The NLCD provides nationwide data on land cover and land cover change at a 30-m resolution with a 16-class legend based on a modified Anderson Level II classification system. Systematically aligned over time, the database offers the ability to understand both current and historical land cover and land cover change to enable assessment of trends. Using the NLCD 2016 dataset, a layer was created by using only three categories out of the 13 to identify impervious areas such as primary roads in urban areas, secondary roads in urban areas, and tertiary roads in urban areas. The new layer was then converted to match the 3-meter spatial resolution from the DEM and the standard State Plane Coordinate system. **Error! Reference source not found.** shows the impervious areas derived from the NLCD 2016 as updated by the future land use map.

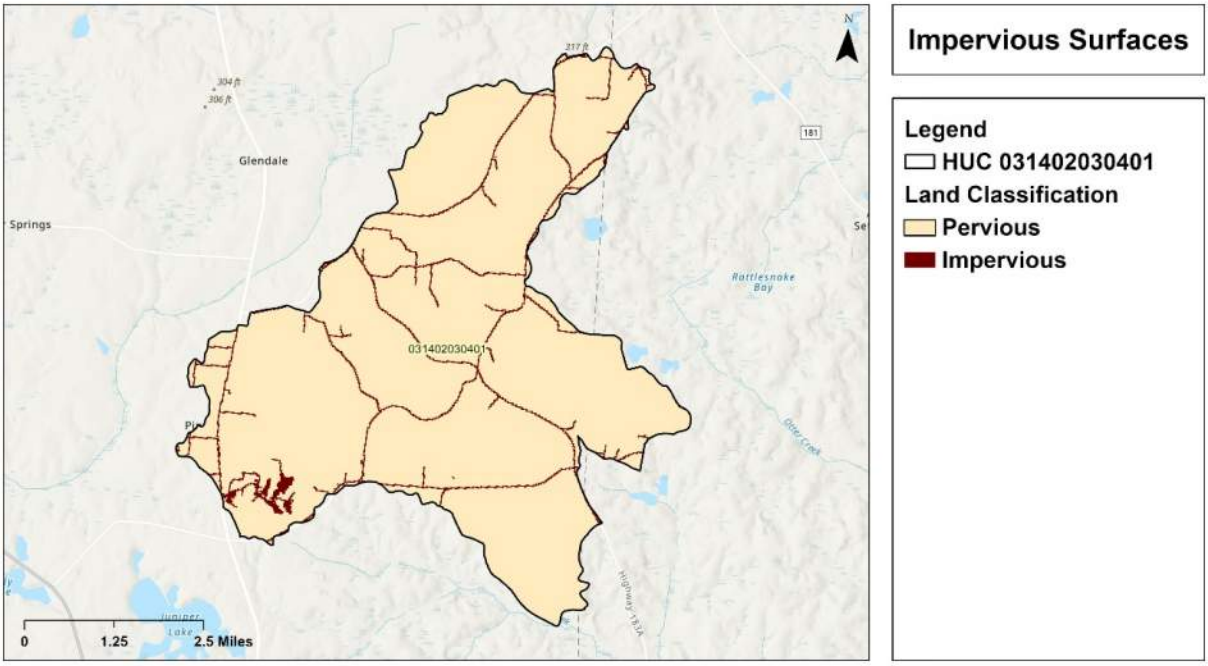

Figure 25. Impervious area map for the HUC 031402030401 sub-watershed, processed by FAU.

1.9 Water bodies

Water bodies were defined in the statewide land use land cover dataset to set soil water holding capacity to zero in model simulations (**Error! Reference source not found.**). Note that tiny water bodies may be missing from the maps. Soils were discussed previously in Section 1.4.

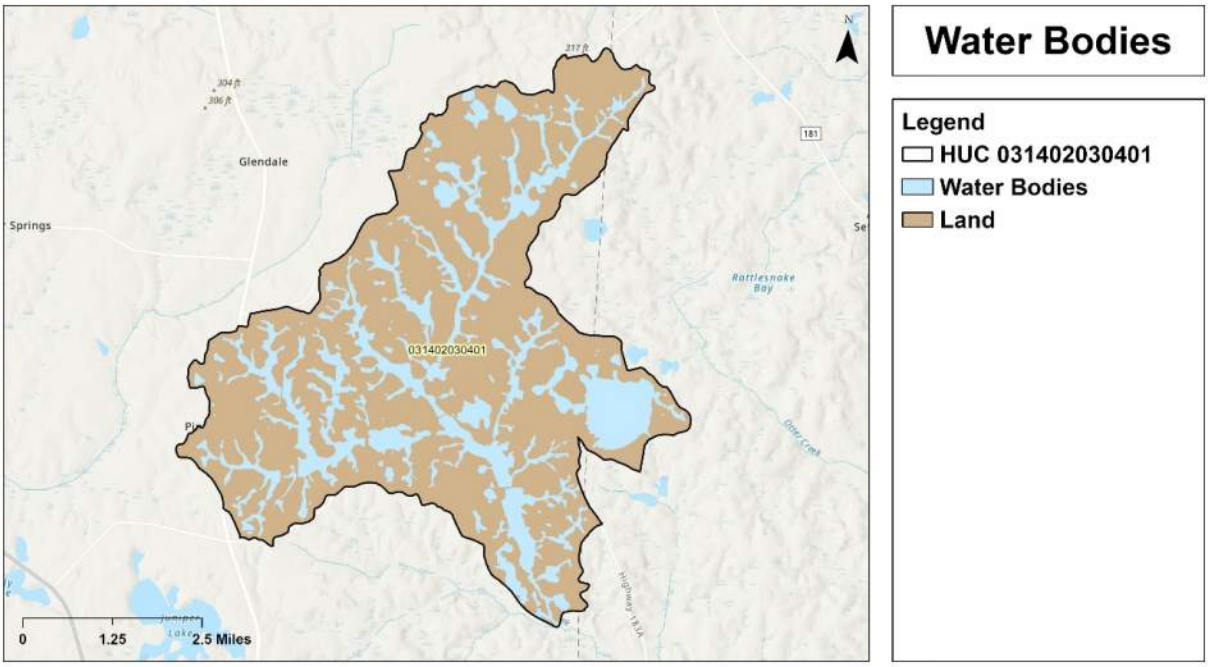

Figure 26. Water bodies map for the HUC 031402030401 sub-watershed, processed by FAU.

1.10 Natural Resources

Understanding the study area's natural resources is critical to identifying potential sources of water quality degradation and areas to designate for conservation, protection, and restoration. One possible goal of watershed master planning is to protect terrestrial wildlife, aquatic habitat, and buffer zones. USGS maintains important sources of information on physical and geographical features as well as soil and mineral resources, surface and ground water resources, topographic maps, and water quality monitoring data. The USDA's Natural Resources Inventory (NRI) (www.nrcs.usda.gov/technical/NRI) is a survey of information on natural resources on non-federal land in the United States that captures data on land cover and land use, soil erosion, prime farmland soils, wetlands, habitat diversity, erosion, conservation practices, and related items. Since 2001, the NRI has been updated continually with annual releases of NRI data from all 50 states. The information provided can be used for addressing agricultural and environmental issues down to the county or cataloging unit level. Therefore, this data can be used to determine erosion and site-specific soil characteristics for certain land uses such as croplands, pasturelands, forestlands, etc., but the data is typically provided as inventories, not GIS layers.

1.11 Demographics

Demographics data is important for determining several key indicators for watershed master planning such as the ability to pay for improvements, social justice issues, land acquisition costs, property/land use, and communication strategies. The US Census has databases at the census tract level. Based on the census data for the study area, **Error! Reference source not found.** outlines population and racial composition demographics.

Table 5. Demographics and Housing Characteristics of Cities and Towns in Walton County.

Demographic Parameter	**Miramar Beach**	**Freeport**	**DeFuniak Springs, City**	**Paxton**	**Rosemary Beach**	**Santa Rosa Beach***	**Walton County**

*It includes the communities of Point Washington to the East and a 15-mile stretch of the Emerald Coast from the east side of Miramar Beach to the west side of Seagrove Beach and the beach communities along 30A, including Grayton Beach and Seaside.

** Census Designated Place

1.12 Stormwater Infrastructure Inventory

Local community stormwater systems consist of drainage ditches, storm sewers, retention ponds and other facilities constructed to store runoff or carry it to a receiving stream, lake, ocean, or other waterbody. Other man-made features include yards and swales that collect runoff and direct it to the sewers and ditches. When most of these systems were built, they were typically designed to handle the amount of water expected during a 10-year storm. Larger storms overload them, and the resulting backed-up sewers and overloaded ditches produce shallow flooding. Another urban drainage problem occurs in the areas protected by levees. Being in floodplains, they are flat and do not drain naturally, especially when a levee blocks the flow to the river. To drain these areas, channels have been built and pumps installed to mechanically move the water past the levee. Often, these man-made systems do not have the capacity to handle heavy rains or intense storms.

Another challenge with stormwater infrastructure is related to recordkeeping. It is not uncommon for stormwater data to be incomplete in most jurisdictions and completely lacking in others. Quality of data differs from jurisdiction to jurisdiction; some are in GIS formats, while others are paper maps or as-builts that represent the infrastructure at a macroscale level. The condition of the assets may be lacking, and the maintenance history may not be available either. Stormwater assets may have been installed with no records, especially in rural areas, farm fields, and private property.

Walton County passed Ordinance No. 2008-06 that prohibits unauthorized discharges into storm drains or ditch systems. In addition, the Public Works Division is currently running a continuous public awareness campaign aimed at encouraging the adoption of best management practices (BMPs) for managing stormwater runoff. This initiative targets both the business community and the residents of Walton County.

To address the issue of flooding, Walton County has implemented several measures along the years, such as:

- Drainage Systems: The county has invested in the development and maintenance of drainage systems, including ditches, canals, and retention ponds, to manage stormwater runoff and reduce flood risk.
- Floodplain Management: Walton County has adopted floodplain management regulations and participates in the National Flood Insurance Program (NFIP) to encourage responsible development in flood-prone areas.
- Elevation Standards: New construction projects within flood zones are required to adhere to specific elevation standards to minimize potential flood damage.

- Emergency Response: The county has established emergency response plans to assist residents during flood events, including evacuation procedures and the provision of emergency shelters.

Key stormwater assets for the HUC and Walton County are indicated in **Error! Reference source not found.** and **Error! Reference source not found.**, respectively. Stormwater structures and management processes in the county consist of stormwater outfall, water wells, weir, pollutant control boxes, inlets catch basins, pipes culverts, ditch conveyance swales, structures, pipes and open conveyance.

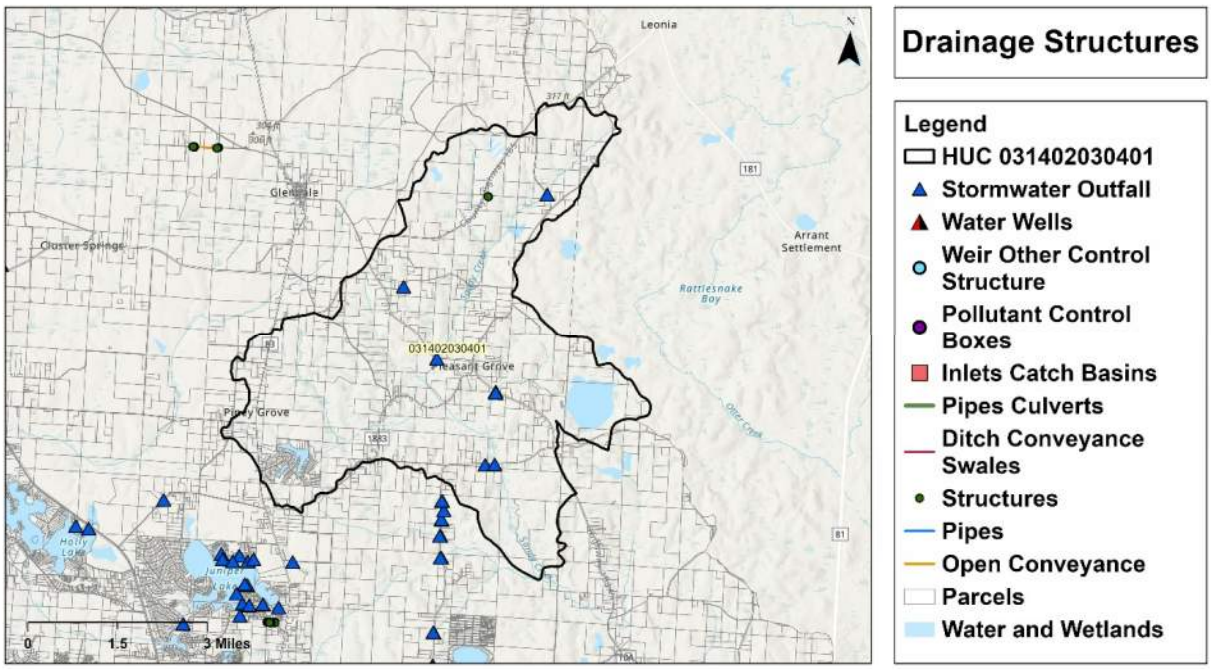

Figure 27. Stormwater Infrastructure for the HUC 031402030401. Processed by FAU.

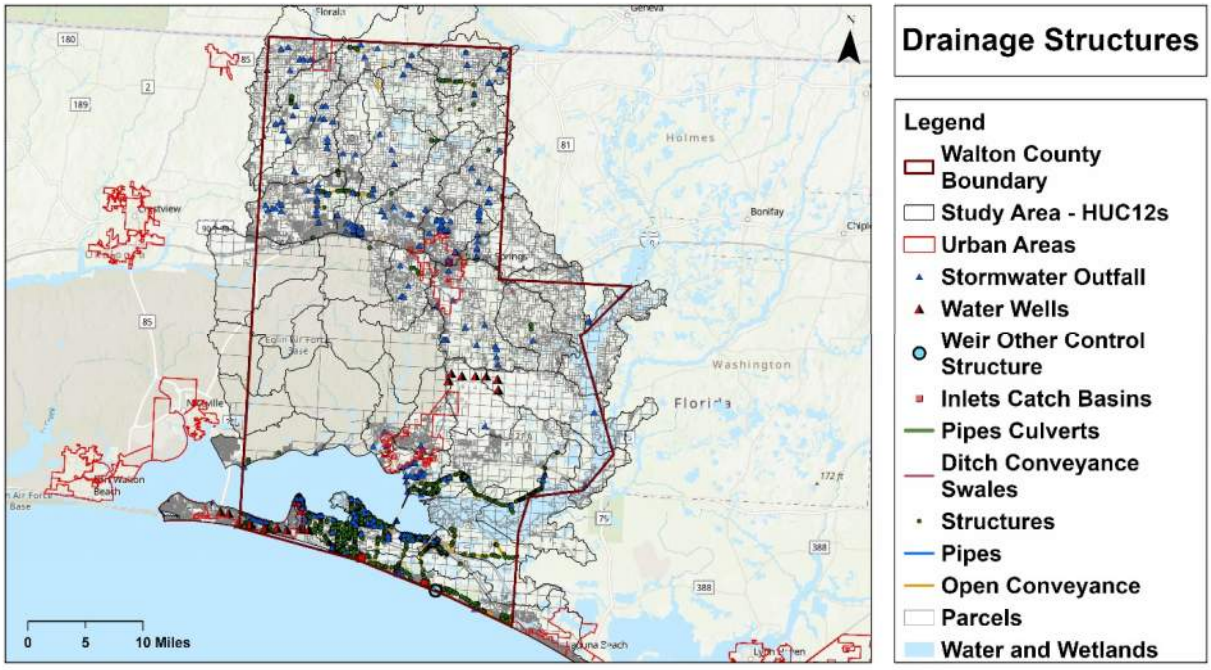

Figure 28.Stormwater Infrastructure for Walton County. Processed by FAU.

Although nature-based infrastructure might be installed, it is not certain. The stormwater system must maintain compliance with the stormwater regulations, which requires record-keeping, policy development, inspections and maintenance. The goals of such stormwater management may include:

- Best landscape practice;
- Control car washing contribution to pollution;
- Enforce the Stormwater Pollution Prevention Plan (SWPPP) by site evaluation, assessment, erosion and sediment controls, preventive maintenance, certification and inspection reporting for construction sites and city planning;
- Implement a hazardous material elimination system;
- Eliminate illicit dumping;
- Proactive and reactive catch basin inspections and maintenance;
- Street sweeping to control debris;
- Maintain swales to help prevent stormwater pollution flooding.

1.13 Data Gaps

FAU has developed comprehensive databases to address the information needed for the vulnerability assessment. These are included in **Error! Reference source not found.**. The data

can be used to model the impacts of flood routing during the storm of interest. As a result, the modeling pieces (discussed in Chapter 2) will include the following:

- Flood response model results (Cascade 2001)
- Flood risk/hazard mapping
- Vulnerability assessments to identify areas of concern for future repetitive losses

There is only one data gap for the area – existing stormwater infrastructure records are incomplete. However, for the purposes of this plan, this data gap does not limit the findings as there are two scales: 1) the sub-watershed level and 2) community hotspots. A neighborhood level vulnerability assessment will require the local infrastructure inventory.

Table 6. List of datasets collected by FAU as of List of datasets collected by FAU for the project (12/20/2020)

2.0 ASSESSMENT OF VULNERABLE AREAS

Defining flood risk due to compounding hydrographic influences is the central concern of this WMP. Modeling and assessment of vulnerability focused on the combination of a high-water table, heavy rains, and impervious conditions that can lead to localized nuisance flooding events. Through a previous survey with local officials, the number of days of continuous nuisance flooding that the public will tolerate before that flooding is considered destructive is about 4 days (E Science 2014).

For a large study area, small parts may actually be at risk. The point is to identify where further study might be needed. A screening tool accomplishes this goal applied to the sub-watershed scale to designate areas that are susceptible to periodic flooding events. Utilizing the information collected and analyzed in Chapters 1, analysis of flood vulnerability can be performed.

2.1 Historical and Existing Challenges

Walton County has faced various historical and existing challenges as well as natural hazards over the years. Some of these include:

- Hurricane and Tropical Storms: being situated along the Gulf Coast, Walton County is vulnerable to hurricanes and tropical storms, which can lead to damage to the built and natural environment, as well as poses risks to human and wild life.
- Coastal Erosion: The county's coastline is subject to erosion due to natural processes and human activities. Erosion can lead to the loss of beaches and threaten coastal structures and properties.
- Flooding: heavy rainfall, storm surges from hurricanes, and other factors can cause localized flooding, particularly in low-lying areas. Flood events can disrupt daily life, damage property, and impact transportation.
- Water Quality and Quantity: as in many coastal areas, managing water quality and maintaining an adequate water supply are ongoing challenges. Pollution from stormwater runoff and other sources can affect water quality, and groundwater resources need to be carefully managed to sustain the growing population.
- Wetland Loss: The county's wetlands face the threat of degradation and loss due to urban development and other human activities. Protecting these essential ecosystems is vital for maintaining biodiversity and mitigating flood risks.
- Urbanization and Development: Balancing the demand for development and growth with the preservation of natural habitats and resources is a persistent challenge. Unplanned

urbanization can lead to habitat destruction, increased runoff, and exacerbate flooding risks.

- Land Use and Zoning: Proper land use planning and zoning are essential to address issues related to population growth, infrastructure development, and natural hazard mitigation. Ensuring responsible development practices can help minimize risks.
- Invasive Species: Like many regions, Walton County faces the threat of invasive plant and animal species. These invasive species can disrupt local ecosystems, negatively impacting native flora and fauna.
- Sea-Level Rise: With rising sea levels due to climate change, coastal communities like Walton County's coastal areas are at greater risk of inundation and storm surges during extreme weather events.

The fast growth of the population and urban development in the coastal areas of the county exacerbates effort to protect open space for land percolation of water. While regulations are in place to reduce the influx of stormwater, the challenges will continue with development.

2.1.1 Existing Management Efforts in the Watershed

The county is under Northwest Florida Management District (NWFMWD) jurisdiction, which covers the Florida Panhandle region. The NWFMWD is responsible for managing and protecting water resources in its designated regions, which includes issues related to water supply, water quality, flood control, and natural resource conservation. Local governments have local stormwater utility infrastructure and planning/policy tools to reduce future flood potential. Most of the major projects to date have been focused on addressing the water quality issues and flooding due to extreme rainfall.

2.1.2 Critical Target Areas Identification

By modeling the HUC 031402030401 sub-watershed flood response to a series of rainfall events (plus king tides), and further classifying flood risk as the probability of inundation, it is possible to identify critical target areas. These areas are particularly vulnerable to flooding and are subject to further study through a scaled-down modeling approach. The screening tool is first applied at the greater watershed level to provide an initial risk assessment focused on the hydrologic response to a rainfall event given the unique characteristics and features of the sub-watershed or study area. The process is discussed later in Section 2.2 with results presented in Section 2.3.

2.1.3 Potential Preservation Areas

Walton County boasts several areas with high biodiversity value. These areas include the unique coastal dune lakes, which support diverse ecosystems and contribute to water quality along the coast. Wetlands are crucial habitats that provide refuge for a variety of plant and animal species while acting as natural water filters. State parks like Topsail Hill Preserve and Grayton Beach State Park are valuable conservation areas with diverse coastal ecosystems. Additionally, preserving the Choctawhatchee River Basin is essential for the biodiversity of the region.

2.2 Vulnerability Maps

2.2.1 Screening Tool

The screening tool utilizes topographic data from various sources (Section 1.1), water table elevations (Section 1.2) and surface water gauges (Section 1.3) downloaded from the NWFWMD DBHYDRO website, tidal information for coastal areas obtained from the NOAA Current & Tides website (Section 1.3), soil maps obtained from the USDA (Section 1.4), and another key dataset as described previously in Chapter 1. The design storms are discussed in Section 1.6. The reason this is critical is that to do any modeling (as required by the CRS program), a screening tool should be used to identify regions with a high risk of inundation based on multiple collected datasets and hydrological models. **Error! Reference source not found.** shows how the GIS layers interface in the tool and how they are combined for spatial analysis.

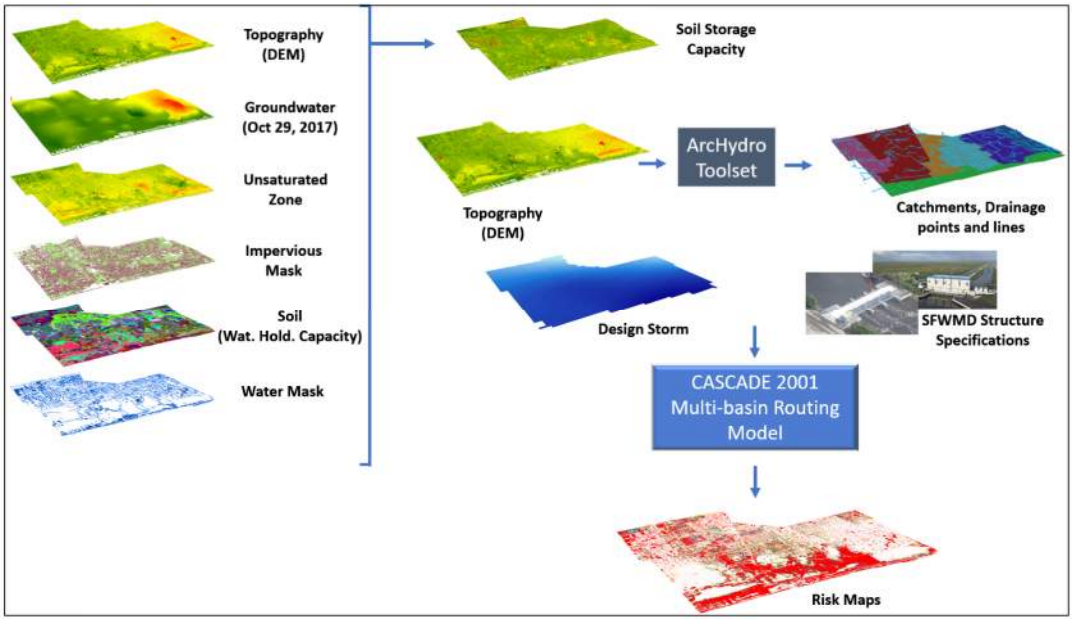

Figure 29. Screening tool methodology for creating flood risk maps.

The model chosen for this screening tool is Cascade 2001, which is a multi-basin hydrologic/hydraulic routing model developed by the SFWMD. The model permits the investigator to run different storm events to determine flooding scenarios. The boundaries are critical for basin studies and must be chosen carefully. The following data layers collected in the prior section are processed to develop the input files for Cascade 2001:

- Topography
- Soils
- Development intensity
- Groundwater elevations
- Surface water/Outlet locations

The software creates a glass box where water rises to a certain level and then decreases. Running the simulation requires defining the basin (HUC or sub-HUC) and input of the following data:

- Area
- Portion of area above a given elevation
- Initial groundwater stage
- Longest travel time for the runoff to reach the most distance point of discharge
- Ground storage as estimated from the USDA gridded National Soil Survey Geographic Database (gNATSGO)

  Ground storage ≈ (Water holding capacity) × (Surface elevation – GW elevation)
  = 2 × (AWS for a soil layer of 0-150 cm) / 150cm × (Surface elevation – GW elevation)

- Available water storage (AWS) for a soil layer of 0-150 cm
- Average amount of precipitation that can be stored in the soil layer

The output from the model is an elevation surface that can be used to develop a flood map for the study area (**Error! Reference source not found.**), which shows the spatial distribution of probabilities of flooding during the modeled 1-day 100-year storm event.

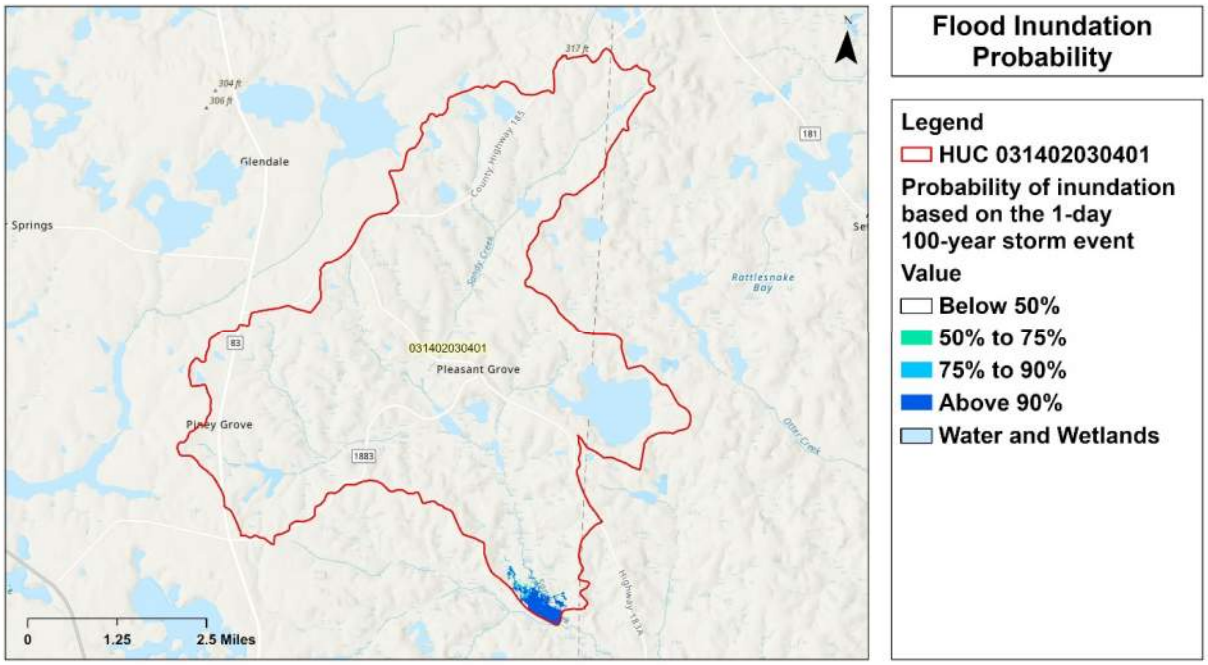

Figure 30. Probability of flood risk map during the modeled 1-day 100-year storm event for the HUC 031402030401, processed by FAU.

2.2.2 Identification of Vulnerable Areas

Given these assumptions and the Cascade 2001 outputs, the goal of this methodology is to produce a spatially-temporally quantified understanding of nuisance-destructive flood potential in the study area given observed values. Risk is a function of compounding geo-hydrological features, namely, surface water, groundwater, topography, build-out, and time of year. A GIS-based algorithm and spatial interpolation generated layers of the greatest observable hydrographic surfaces. These outputs were then compared with high resolution topographic LiDAR data to develop digital elevation models that reflect the observed risk landscape. These models can then be combined into Cascade 2001 to produce vector and volume information, in combination with soils, vegetation and impervious surfaces, allowing the observed model outputs to be extrapolated into a more predictive context.

To evaluate flood vulnerability at this scale, the analysis starts with a binary flooding surface (0 = below 50% chance of flooding; 1 = above 50% flooding) based on output from the screening tool for a specified design storm. Next, attributes of that raster based on "VALUE = 1" query are extracted using *Extract by Attributes* tool. Then the *Batch Project* tool was used to map critical facilities data to the common coordinate system (NAD83 UTM Zone 17N), unit = meters. Then a field was added using *Add Field* for [PriorityTier] = assigned Tier #1-4 value from the DOR codes

and [Area_sqmeter]. The critical facilities layers were then merged into a single layer to calculate the polygon geometry for [Area_sqmeter] using the *Merge* tool. Next, *Zonal Statistics as Table* is used to calculate the SUM of flooded values ("VALUE = 1") within each critical parcel. Output table has fields for SUM (i.e., total # of flooded pixels per critical parcel) and AREA in map units of square meters (since each pixel in the flooding surface has a cell size of 3-meters by 3-meters, each area is equal to the SUM value multiplied by 9 m^2). Using the *Join Field* tool, the SUM and AREA fields are joined to the merged critical facilities layer based on a key attribute, first renaming these fields for clarity (e.g., AREA_FLOODED_3d25y). Once all field data is included, the next step involves using *Export Table* to export the dataset as a CSV file. Note that non-flooded parcels have zero flooded area, so they receive a <Null> value from the zonal statistics tool. To replace null values with zeros, we use *Calculate Field* in the attribute table along with the following Python expression (replacing the respective field name): "0 if !AREA_FLOODED_3d25y! is None else !AREA_FLOODED_3d25y!". Next, the CSV file is saved as an Excel Workbook (.xlsx). The Range is converted to an Excel Table, and the columns are rearranged in the desired order. Finally, the "percent-flooded" columns are calculated as follows:

- PCT_FLOODED_3d25y = ([@[AREA_FLOODED_3d25y]]/[@[TotalArea_sqmeter]])*100
- PCT_FLOODED_1d100y = ([@[AREA_FLOODED_1d100y]]/[@[TotalArea_sqmeter]])*100

After this calculation, the table is sorted to show the higher priority tiers and higher percent-flooded values first. To reduce the number of critical facilities shown in the final table, a filter was created to show only critical facilities with 10% or more flooded area in the parcel during both storm events. Records with duplicate parcel ID numbers were removed from the table. The results of this procedure are discussed in Section 2.4 of this document.

With respect to dams and levees, for purposes of the NFIP, FEMA only recognizes systems that meet, and continue to meet, minimum design, operation, and maintenance standards that are consistent with comprehensive floodplain management criteria. The Code of Federal Regulations, Title 44, Section 65.10 (44 CFR 65.10) describes the information needed for FEMA to determine if a levee system reduces the risk from the 1% annual chance flood. FEMA has accredited levees and Provisionally Accredited Levees (that have a specified timeframe to obtain the necessary data to confirm the levee's certification status). If a levee system no longer meets Section 65.10, FEMA will de-accredit the levee system and issue an effective FIRM showing the levee-impacted area as a SFHA. FEMA coordinates its programs with USACE, who may inspect, maintain, and repair levee systems. USACE has authority under Public Law 84-99 to supplement local efforts to repair flood control projects that are damaged by floods. Like FEMA, USACE provides a program to allow public sponsors or operators to address levee system maintenance deficiencies. Failure to do so within the required timeframe results in the levee system being placed in an inactive status in

the USACE Rehabilitation and Inspection Program. Levee systems in an inactive status are not eligible for rehabilitation assistance under Public Law 84-99. There are no levees/dams listed in the sub-watershed study area.

2.3 Modeling Results

Error! Reference source not found. to **Error! Reference source not found.** are a series of maps that depict risk of flooding in the basin based on the following scenarios:

1. 3-day 25-year storm event. Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (**Error! Reference source not found.**)
2. 1-day 100-year storm event. Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (**Error! Reference source not found.**)
3. 1-day 10-year storm event. Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (**Error! Reference source not found.**)
4. 1-day 5-year storm event. Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (**Error! Reference source not found.**)

In all storm event scenarios, a small portion of flooding is noted at the creek entrance to the HUC. As this basin is not connected to the ocean and its altitude is above 20 feet, the HUC is expected to remain unaffected by sea level rise, therefore SLR scenarios were not computed.

The design storm simulation determined that approximately 0.71% of the HUC total area or 0.19 mi² has a probability of inundation above 50% for a 3-day 25-year design storm. For comparison, approximately 0.76% of the HUC's total area, or 0.20 mi² would be expected to be inundated during a 1-day 100-year design storm. Approximately 0.52% of the HUC's total area, or 0.14 mi², would be expected to be inundated during a 1-day 10-year design storm. Finally, approximately 052% of the HUC's total area, or 0.14 mi², would be expected to be inundated during the 1-day 5-year storm. **Error! Reference source not found.** compares the four storm events.

Table 7. HUC 031402030401 expected inundated area by storm event.

Storm Event	Area with probability of inundation below 50% (Sq Mi)	Area with probability of inundation above 50% (Sq Mi)	Area with probability of inundation below 50% (%)	Area with probability of inundation above 50% (%)
3-day 25-year	26.79	0.19	99.29%	0.71%
1-day 100-year	26.78	0.20	99.24%	0.76%
1-day 10-year	26.84	0.14	99.48%	0.52%

1-day 5-year	26.84	0.14	99.48%	0.52%

Processed by FAU.

2.4 Risk and Vulnerability

The screening tool modeling exercise from the prior section identified areas within the communities that are vulnerable to flooding. Higher priority concerns should be those properties or assets that are considered essential and need to be kept in service during a flooding event. All other improvements are local. To help with prioritization, the following is suggested:

- Tier 1 - Critical facility protection (water/sewer utilities, public safety, hospitals, schools, power, shelters)
- Tier 2 - Essential facilities (groceries, pharmacies, roadways)
- Tier 3 - Economic centers (protecting jobs)
- Tier 4 - At risk communities
- Tier 5 - Other urban/suburban property
- Tier 6 - Agriculture/public property/vacant/undeveloped

Error! Reference source not found. outlines the priority of land use based on DOR land use codes from the property appraiser's office and assigns an associated priority level to each parcel. Note that for residential property, identifying at-risk communities (income, age, disability, health) requires a further drilldown to the neighborhood level (i.e. wealthy neighborhoods with few older, poor health individuals would have a lower priority than at risk communities, which generally have lower value housing and denser development). In the latter case, more people are impacted, and those people have less ability to mitigate risk. Based on these priorities, the relative risk priority DOR land use codes were evaluated based on a scale of 1 to 6, where 1 is higher priority (more vulnerable) and 6 is the least priority (least vulnerable).

Table 8. Priority of Land Use based on (DOR) land use codes. Processed by FAU.

Having assigned the risk priority from 1 to 6 in the DOR codes and the percentage of the parcel that floods during the applicable design storm, properties that are more critical to the function of the community can be identified. The methodology is to first convert the DOR code priority tier to its inverse scale by the following equation:

Consequence of risk factor = 7 – DOR Code Priority Tier

The flood risk factor from the screening tool is interpreted based on flooding probability. We take all parcels in tiers #1-4 that have a greater than 50% chance of flooding during a particular design storm and calculate the percent of the parcel that would flood during that event. The percentage is converted to a 6-point scale termed as the Flood Risk Factor, shown in **Error! Reference source not found.**.

Table 9. Flood Risk Factor Classification.

Percent of Parcel Flooded	Flood Risk Factor
90-100%	6
80-89%	5
70-79%	4
60-69%	3
50-59%	2
<50%	1

The priority is further developed by assigning 75% of the importance to the consequence of flooding and 25% importance to flood risk, or three times the importance to the consequence of flooding to come up with a composite score as follows:

Flood Risk Factor × 25% + Consequence of Risk Factor × 75% = Composite Score

Example: 1 × 25% + 6 × 75% = 4.75

Those higher priority properties that received the higher composite score are where the mitigation strategies and financial resources should focus first.

2.4.1 Results

Error! Reference source not found. and **Error! Reference source not found.** depict the HUC 031402030401 sub-watershed priority of land uses showing the critical facilities that should receive priority. The first map (**Error! Reference source not found.**) exclusively displays critical facility parcels within the HUC without any flooding. The second map (**Error! Reference source not found.**) overlays critical facilities onto the 1-day 100-year storm event scenario. **Error! Reference source not found.**is a mosaic showing critical facilities overlaid in the 1-day 100-year storm event for the whole county.

Additionally, **Error! Reference source not found.**illustrates the composite score based on 1-day 100-year storm event for the HUC, which is the result of the calculations explained above, pinpointing parcels that should be prioritized. It considers only parcels classified as 1 to 4 tiers, and within the 50% probability of inundation area. Lastly, **Error! Reference source not found.** is a mosaic showing the results for composite score overlaid in the 1-day 100-year storm event for the coastal area of Walton County. As the subwatershed is not coastal, the results based on 5 ft. SLR + 1-day 100-year storm event were not computed for the basin.

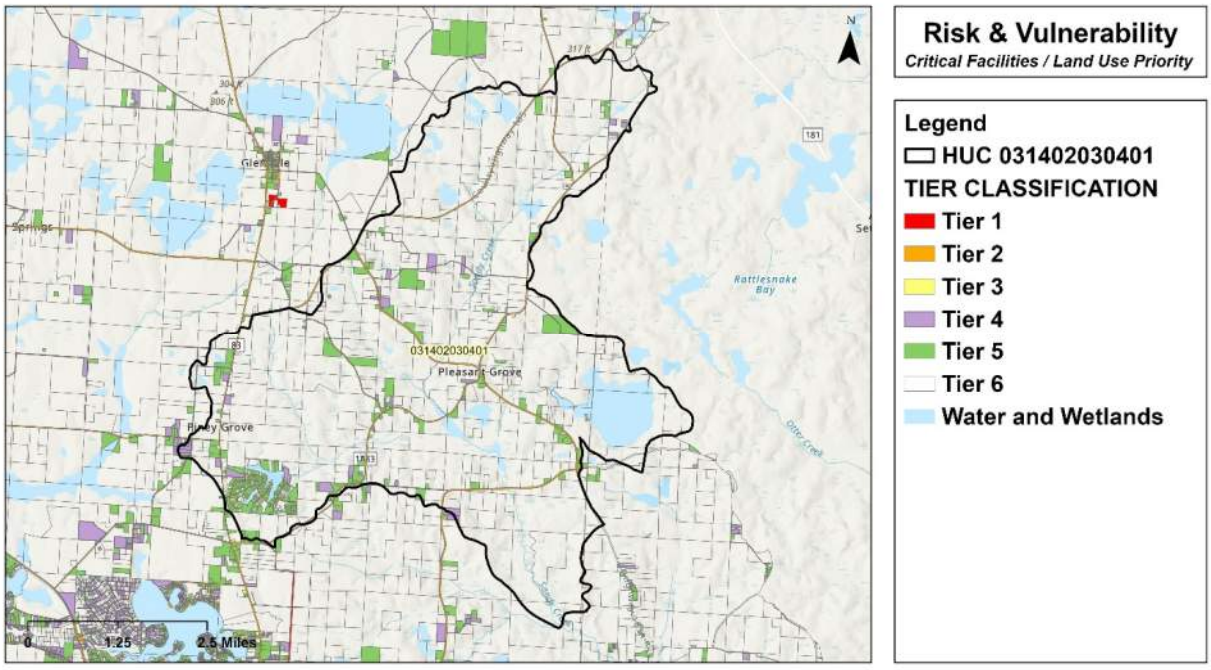

Figure 35. HUC 031402030401 sub-watershed Critical Facilities (priority of land uses) map. Processed by FAU.

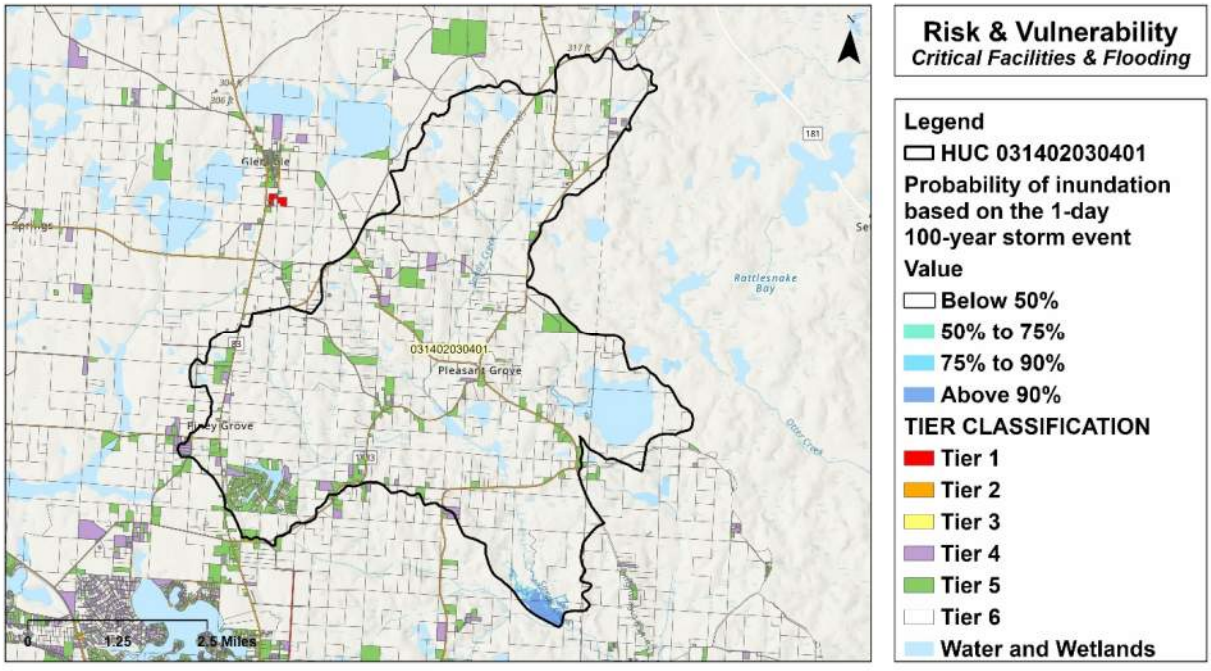

Figure 36. HUC 031402030401 sub-watershed Critical Facilities (priority of land uses) map overlaid on the 1-day 100-year storm event probability of inundation. Processed by FAU.

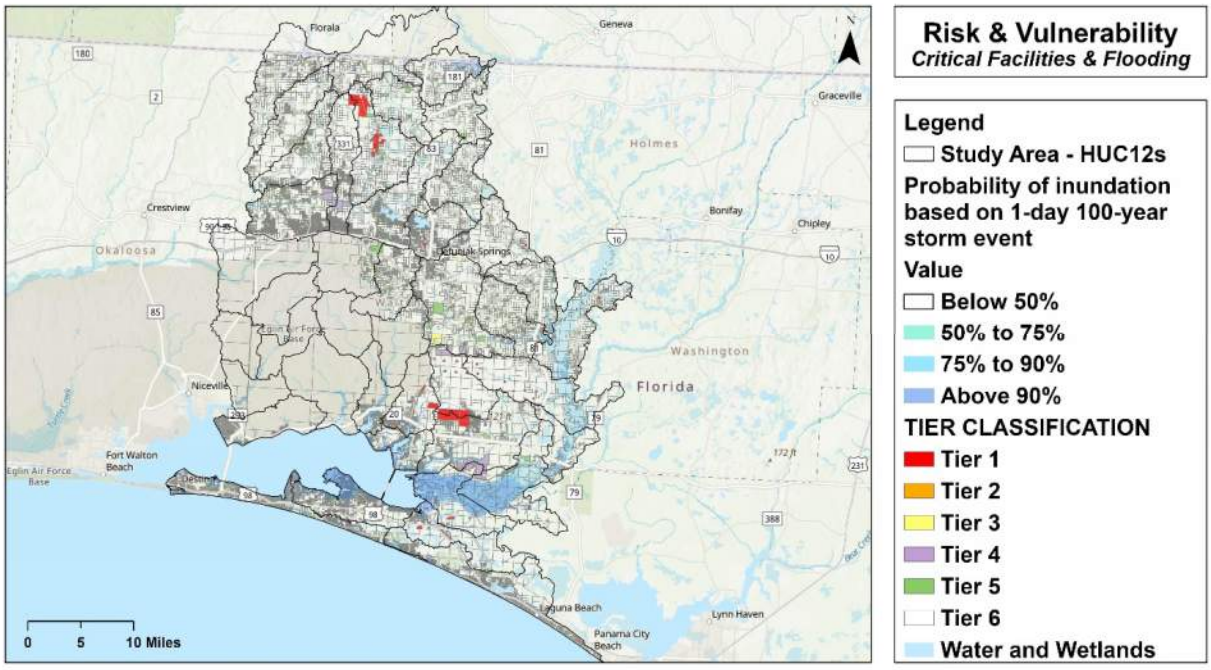

Figure 37. Walton County (mosaic) - Critical Facilities (priority of land uses) map overlaid on the 1-day 100-year storm event probability of inundation for Walton County. Processed by FAU.

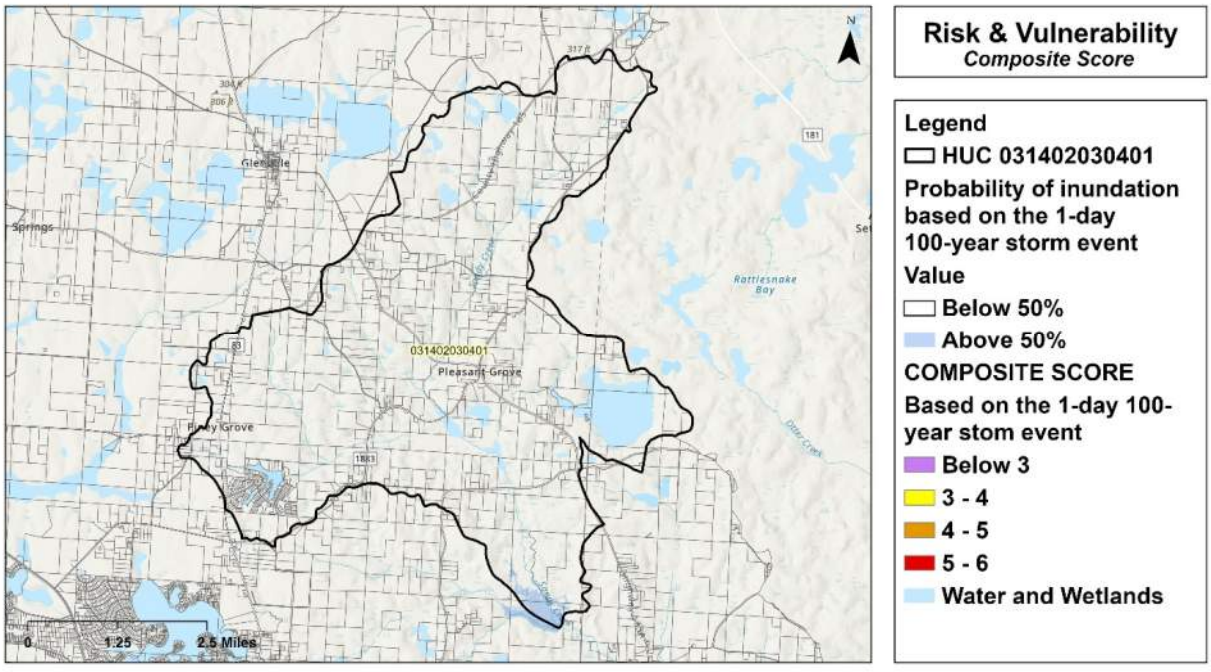

Figure 38. HUC 031402030401 sub-watershed Composite Score Risk map, with calculation based on 1-day 100-year storm event. Processed by FAU.

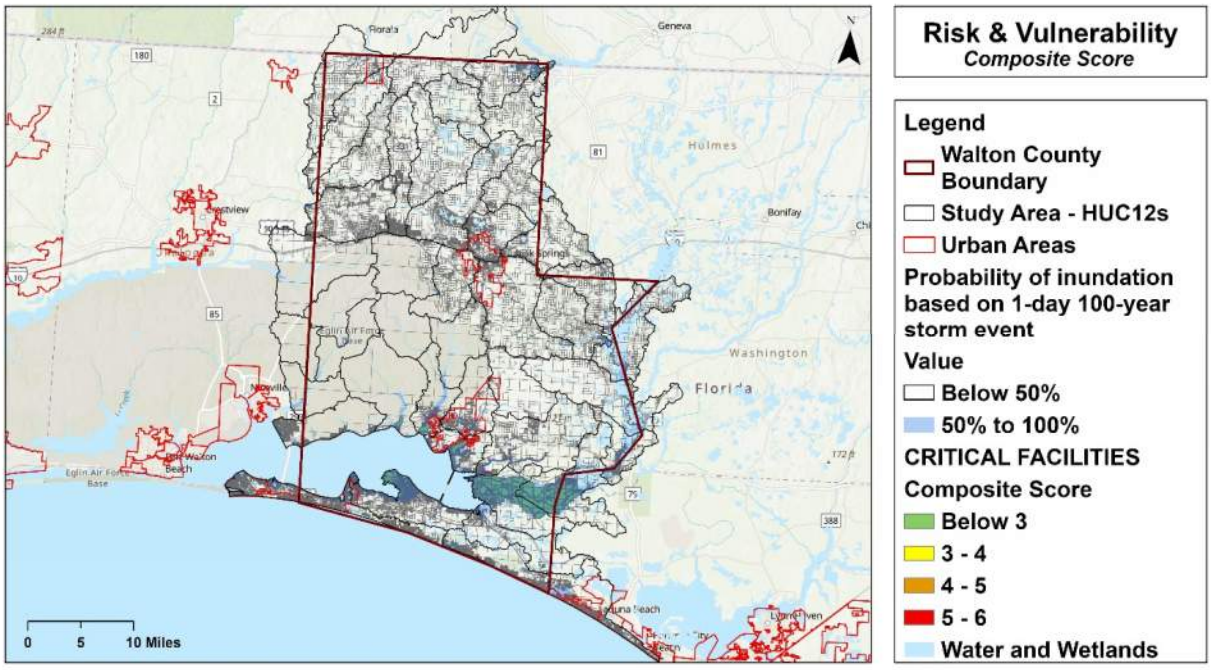

Figure 39. Walton County (mosaic) - Composite Score Risk map overlaid on the 1-day 100-year storm event probability of inundation. Processed by FAU.

Please note that due to the scale of the map, the composite score layer is not properly visible in this map.

Please note that the composite score results display outcomes exclusively for parcels within the flooding path area. Consequently, for parcels outside this flooding path, the composite results will be null. The composite score combines the flooding path area with the land use priority results to identify the most vulnerable areas deserving of priority.

2.4.2 Solutions

Chapter 5 of the Watershed Master Plan for Walton County describes a list of possible gray and green stormwater strategies to combat flooding that can be implemented as solutions for the county. The same solutions can also be applied at the HUC level, including HUC 031402030401. A summary of these flood mitigation strategies is listed in **Error! Reference source not found.**. For more detailed information, please see Chapter 5-5.3 (Solutions).

Table 10. List of possible gray and green stormwater strategies to combat flooding.

Strategy Class	Implementation Strategy	Applications	Benefits	Cost	Barriers to Implementation
Green	Rainwater harvesting	Local, small scale, easily implemented in developed areas	Protects property, treats runoff	Under $5,000	Limited volume disposed of, so many are needed, maintenance
Gray	Pervious paving	Parking lots, patios, driveways, anything except paved roads due to traffic loading	Reduces roadway and parking lot flooding	$10-20/sf, requires bumpers and sub-base to maintain paver integrity	Must be maintained via vacuuming or the perviousness fades after 2-3 years
Green	Detention	Common for new development, but difficult to retrofit; limited to open areas	Removes water from streets, reduces flooding	$200K/ac	Land availability, maintenance of pond, discharge location Uses up land that could otherwise be developed
Gray	Exfiltration Trench	Any low-lying area where stormwater collects and the water table is more than 3 ft below the surface; densely developed areas where retention is not available, roadways	Excess water drains to aquifer, some treatment provided	$250/ft	Significant damage to roadways for installation, maintenance needed, clogging issues reduce benefits
Gray	Central sewer installation	All areas where there are septic tanks. Mostly a water quality issue	Public health benefit of reducing discharges to lawns, canals, and groundwater from septic tanks	$15,000 per household	Cost, assessments against property owners, property rights issues
Green	Flood prone property acquisition	Regional agency - could be any low-lying areas	Removes flood prone areas from risk	$2K-$100K/ac depending on whether it is already developed	Difficult to implement if occupied, issues with willing sellers, cost, lack of funds for acquisition

Strategy Class	Implementation Strategy	Applications	Benefits	Cost	Barriers to Implementation
Gray	Pump stations	Any low-lying area where stormwater collects, and there is a place to pump the excess stormwater to such as a canal; common for developed areas	Removes water from streets, reduces flooding	Start at $1.5 to 5 million each, number unclear without more study	NPDES permits, maintenance cost, land acquisition, discharge quality
Gray	Armored sewer systems	Any area where gravity sanitary sewers are installed	Keeps stormwater out of sanitary sewer system and reduces potential for disease spread from sewage overflows	$500/manhole	Limited expense beyond capital cost
Gray	Sea walls	Barrier islands and downtown coastal areas	Protects property	$1200/ft	Private property rights, neighbors
Policy	Changes in land use	Applicable universally	Achieves flood risk mitigation by adjusting permitted land use	Low but may incur private property rights conflicts and litigation	Private property rights conflicts and litigation
Gray	Roadway base protection	Low-lying areas, coastal communities	Protects roads and access routes	$1 million per lane-mile	Cost, adjacent properties become uninsurable
Policy	Enhanced elevation of buildings	Developers would implement this for new construction	Reduced flood risk	Varies	Potential issues with building structure or latticework, and existing homes that are not elevated

2.4.3 Impacted Adjustment Areas

In the evaluation of flood risk management strategies within the framework of the National Flood Insurance Program Community Rating System (CRS), the concept of impact adjustment plays a pivotal role in determining the extent to which CRS-credited activities or elements influence the vulnerability of a community's Special Flood Hazard Area (SFHA) and the structures located within it. It's important to note that while the usual results of impact adjustment are related to the SFHA area, in this specific analysis, it was used 1-day 100-year storm event inundation area performed by FAU instead.

In this context, the following table presents a breakdown of the impact adjustment calculations for a 1-day 100-year storm event inundation. The values are expressed in acres and depict the areas of interest as well as the deductions considered in the evaluation process.

The outcomes of these calculations provide valuable insights into the impact adjustment scenarios:

With ALL State Lands:

This scenario reflects the remaining inundation area after accounting for deductions A, B, and C. It represents the effect of CRS-credited activities without considering the influence of state lands in managing flood risks.

With NO State Lands:

In this case, the remaining inundation area is determined by considering all deductions, including state lands (both open space and not open space – see **Error! Reference source not found.**).

These calculations highlight the dynamic nature of impact adjustment within the CRS framework. By accurately gauging the influence of individual elements, the system ensures that credit allocations align closely with a community's efforts in flood risk mitigation.

Table 11. Impacted Adjustment Areas for HUC 031402030401. Processed by FAU.

AREAS	**ACRES**
HUC-12 Sub-watershed: 031402030401	17267.54
All of the 1-day 100-year storm event inundation	**130.73**
Subtract	
A. Bodies of Water in 1-day 100-year inundation > 10 acres	0.00
B. Federal Land in 1-day 100-year inundation > 10 acres	0.00
C. Reservation/Tribal Land in 1-day 100-year inundation > 10 acres	0
D. State Land in 1-day 100-year inundation > 10 acres that is open space	0.00
E. State Land in 1-day 100-year inundation > 10 acres that is NOT open space	0.00
The remainder is either:	
With ALL State Lands: All of the 1-day 100-year inundation minus (A+B+C) or	130.73
With NO State Lands: All of the 1-day 100-year inundation minus (A+B+C+D+E)	130.73

2.4.4 Repetitive Loss Property Map

A Repetitive Loss (RL) property is a building that has had two or more loss or damage due to a specific hazard, such as floods, hurricanes, or other natural disasters, over $1,000 each, paid by the National Flood Insurance Program (NFIP) within any ten-year period since 1978. There are more than 122,000 RL properties in the nationwide (FEMA, 2005).

These data are essential for assessing the vulnerability of certain areas to recurrent losses and for developing strategies to mitigate the risks. However, due to privacy concerns, the data cannot be openly shared with the public. For this reason, the data were converted into a hot spot analysis map. These maps, instead of identifying the specific location of the repetitive loss properties, highlight clusters of repetitive loss claims and areas where the probability of repetitive losses is higher than would be expected by random chance. In other words, it helps pinpoint locations that have a higher concentration of properties prone to repetitive losses. **Error! Reference source not found.** indicates the results from hot spot analysis in point data, showing aggregated counts, and raster data, showing the estimated probability of repetitive loss.

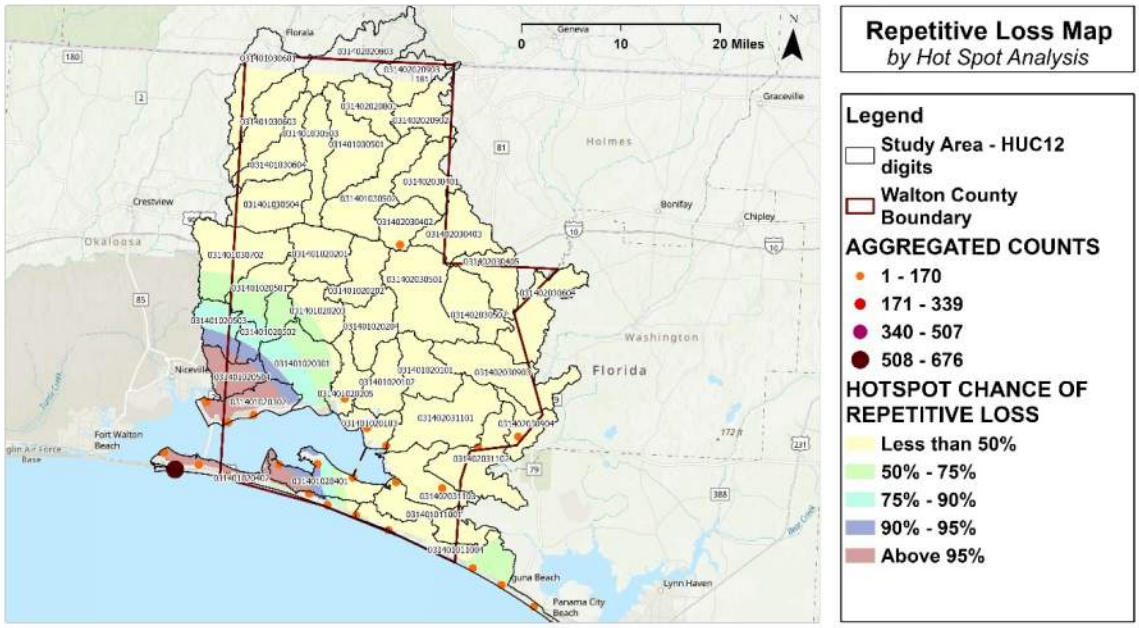

Figure 40. Repetitive Loss map for Walton County by Hot Spot Analysis. Processed by FAU.

2.4.5 Priority Projects

Although there are a good amount of parcels falling within tiers 2 (roads), 4 and 5 of priority of land uses, none of them are within the flooding zone, once flooding in the area is minor and not alarming. Consequently, when considering the composite score, it is notable that the results are null, indicating no priority for intervention within the basin.

X.0 EXECUTIVE SUMMARY

The goal of the appendices to the watershed plan are to outline the issues associated with the individual HUC12s that contribute or impact the community's flood vulnerability and there for its flood protection efforts. Floodplain analysis includes developing a watershed model and identifying associated inundation polygons. It builds upon information generated from the watershed evaluation so that planning and management decisions can be formulated.

This appendix describes the issues and modeling associated with one of the HUC12s that affects Walton County. In developing the County-wide plan, this HUC 12 was analyzed so as to determine how it brings or removes floodwaters from the County. For the NFIP process the goal is to analyze all communities at the HUC12 level. From a community perspective the HUC12 is less useful to residents than a community-wide plan. Hence in all cases the HUC12 results were mosaicked into the community-wide plan. Details can be found in the HUC12 appendices, some of which were brought into the community plan.

To reduce redundancy, information of the plans, ordinances, policies and regulations were rolled up to the community-wide plan and will not be repeated in the appendices. Likewise, the community wide mapping was parced for HUC12 use.

1.0 WATERSHED CHARACTERIZATION

In this section, key aspects of the watershed are characterized. This is important for later being able to identify the most vulnerable areas and to mobilize resources to implement an action plan. Understanding the characteristics of the watershed involves gathering existing information and data sets from previous planning efforts. It is important to note that this step is iterative and ongoing as new data are generated and projects are implemented and monitored.

To assess the historical and current conditions of the study area, the following existing data sets that characterize the physical and natural features of the watershed were obtained for each HUC-12 subwatershed in the study area:

- Topographic data (LiDAR)
- Relevant waterway locations
- Groundwater levels
- Soils data
- Land uses including vacant land, wetlands, impervious, etc.
- Precipitation records
- Catchment delineations for flood routing

In addition, the FEMA flood maps must be obtained, and the storm of interest must be identified for screening purposes (1-day, 2-year, 5-year, and 100-year events as well as the 3-day 25-year storm event to achieve class 4 in the CRS Manual). In developed areas, many sources of data are already available – the key is putting the key datasets in a format that can queried for screening to identify the priority areas of the watershed. Table 6 is a summary of datasets available at cwr3.fau.edu that were used to construct this plan.

This watershed master plan is a drilldown of the larger Walton County TMDL region, which involves 42 HUC 12-digit sub-watersheds (**Error! Reference source not found.**). **Error! Reference source not found.** shows Walton County Drainage Network and the location of urban areas (cities and towns). In **Error! Reference source not found.**, the HUC-12 digits (031402030402) is highlighted among all the HUCs to help identifying its location.

The city of DeFuniak Springs shares a portion of its boundary with the basin. Demographics data and other considerations of DeFuniak Springs, along with other cities in Walton County, will be covered in subsequent discussions.

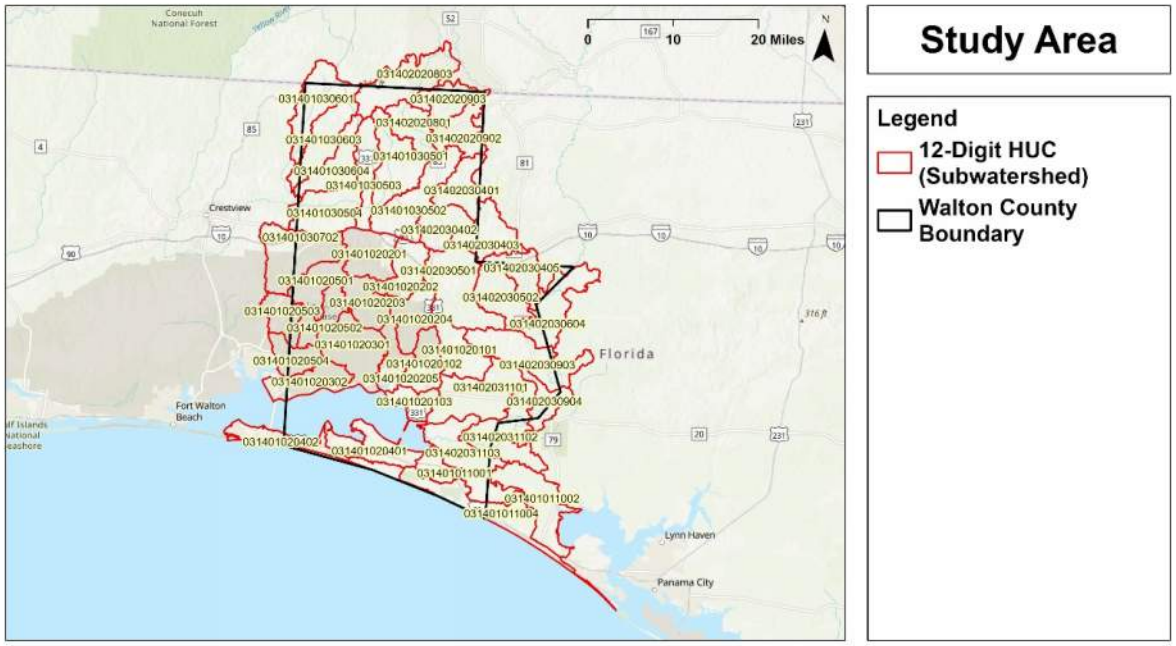

Figure 1. Walton County and all HUCs 12-digit subwatershed, processed by FAU.

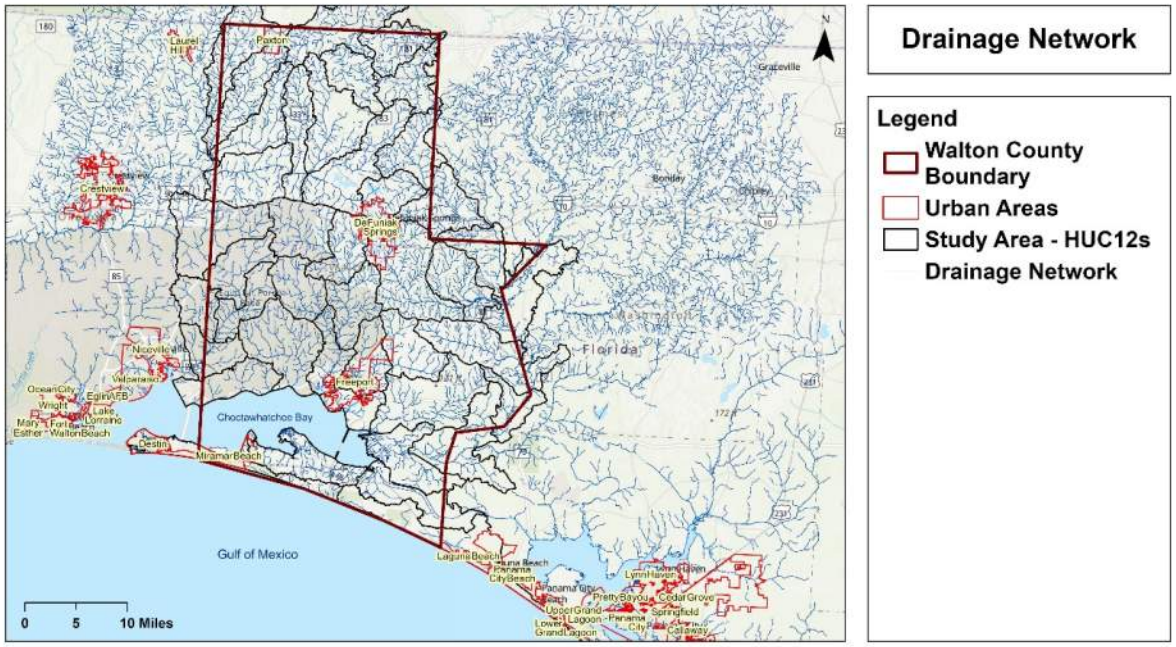

Figure 2. Walton County Drainage Network and urban areas (cities and towns), processed by FAU.

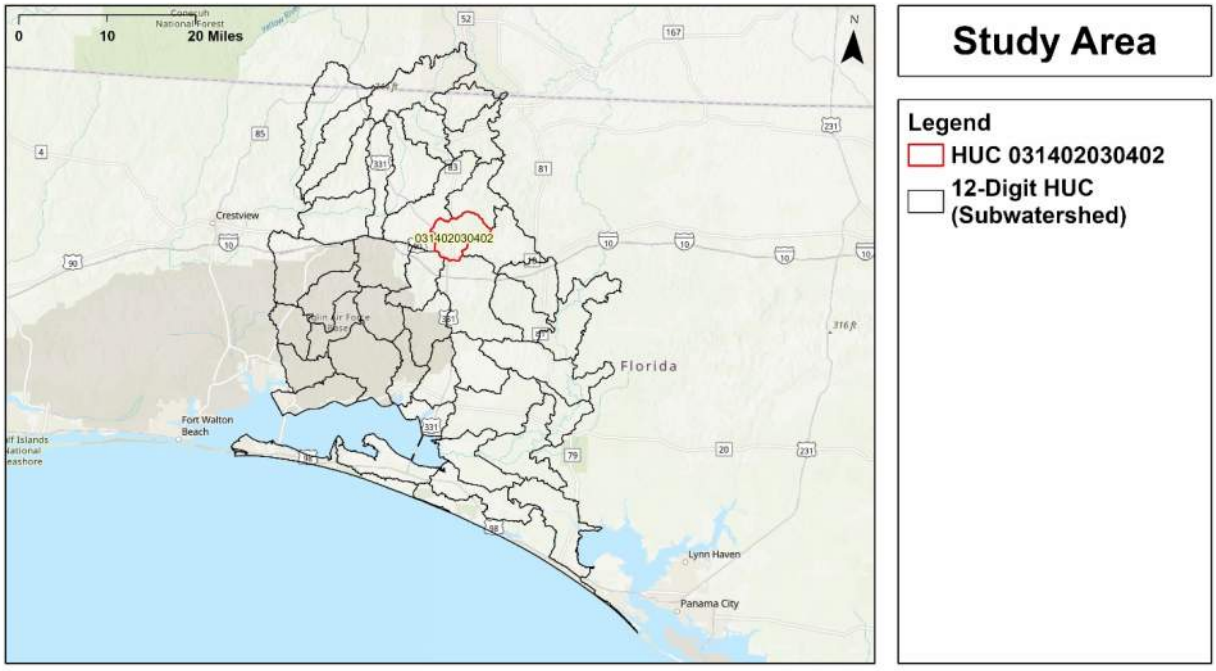

Figure 3. HUC 031402030402 sub-watershed location.

Located in the northwestern region of Florida, Walton County has 1,037.7 square miles of land and it is the 12th largest county in Florida by area, while also sits the highest point in the state, with a height of 345 feet in its northern end. With a population of 75,305 residents according to

the 2020 census and an estimate population in July of 2022 of 83,304, the county has experienced consistent growth within the past several years, driven by factors such as tourism, retirement migration, and regional population dynamics. The county was the residence for 55,043 people according to Census 2010, which leads to a percent change of 36.8% in 10 years, between 2010 and 2020, and a percentage change of 10.6% in two years, between 2020 and 2022 (United States Census Bureau).

The surge in population, particularly in the southern part of Walton County, has resulted in a corresponding expansion of infrastructure to cater to the growing needs. Essential facilities such as potable water systems, wastewater treatment plants, electrical utilities, roads, and schools have been developed to support this increasing population. However, the infrastructure expansion has brought about a significant change in the natural environment. Prior to the existing development , tropical cyclone impacts would be mitigated by natural barriers such as vegetated sand dunes, wetlands, and deserted beaches, which would absorb some of the destructive forces. Now, with the proliferation of costly infrastructure and residential dwellings in coastal areas, these storms pose a higher risk of potential damage. The very areas where development is occurring are becoming more vulnerable to the impact of severe storms, highlighting the importance of considering and implementing adequate measures to address potential storm damage in these coastal regions (Walton County Local Mitigation Strategy Plan, 2015).

Demographically, Walton County presents a heterogeneous age distribution, encompassing a blend of younger and elderly cohorts. The median age of approximately 44 years reflects the presence of both younger families and retirees seeking a serene and picturesque environment. Ethnically, the county' population is predominantly White with smaller yet notable populations of Hispanic/Latino, African American, and other racial/ ethnic groups.

Economically, the tourism sector stands as a dominant force in Walton County, constituting 23.4 percent of the workforce, according to Walton County Economic Development Alliance in 2011, due to its renowned beach destinations, such as Santa Rosa Beach, Miramar Beach, and the New Urbanist Communities of Seaside and Rosemary Beach. Following closely behind is the trade, transportation & utilities sector, accounting for 20.3 percent of employment, while construction stands at 10.0 percent in third place. Education, health care services, and public administration also play significant roles within the top five employment sectors, reflecting the diversified economic landscape of the county (Walton County Local Mitigation Strategy Plan, 2015).

The natural environment in Walton County contributes to its distinctive appeal to visitors and tourists. The county's coastal environment along the Gulf of Mexico showcases picturesque vistas, including white sand beaches, undulating dunes, and coastal dune lakes. These lakes, a rarity worldwide, provide unique ecological habitats. Walton County is also committed to environmental conservation, with designated protected areas comprising state parks, forests, and wildlife management zones. These preserved landscapes offer abundant opportunities for recreational activities, including hiking, fishing, and birdwatching.

The presence of wetlands and waterways further enhances the natural attributes of Walton County. Various rivers and creeks alongside Choctawhatchee Bay permeate the landscape, fostering

diverse ecosystems and serving as crucial habitats for a wide range of wildlife species. This rich natural heritage encourages exploration and nurtures an appreciation for the environment.

DeFuniak Springs serves as the county seat and boasts a diverse economy. Anchored by sectors such as healthcare, education, retail, government services, and a thriving small business community, DeFuniak Springs offers a range of employment opportunities. Surrounded by the natural beauty of forests, lakes, and wetlands, the city enjoys the presence of Lake DeFuniak, a noteworthy natural resource. With a population of approximately 5,100 residents, DeFuniak Springs is a vibrant city featuring a mix of economic activities. The land area of DeFuniak Springs is approximately 12.6 square miles (32.7 square kilometers).

Freeport boasts a diverse demographic profile, and a developing economy. The city is situated along the shores of Choctawhatchee Bay, which provides opportunities for recreational opportunities and supports local ecosystems. Surrounded by lush forests and intersected by waterways, Freeport enjoys a rich environmental setting. In terms of economics, Freeport's economy is in a phase of growth and diversification, with sectors including healthcare, education, retail, and small businesses. The city is also strategically positioned for future economic expansion due to its proximity to major transportation corridors. Demographically, Freeport is a close-knit community with a population of approximately 2,600 residents, comprising a mix of permanent residents, retirees, and individuals seeking a suburban or rural lifestyle. The city reflects a diverse demographic composition, showcasing a variety of cultures, and backgrounds. Freeport occupies a land area of about 13.6 square miles (35.3 square kilometers)

Further along the coast, Miramar Beach stands as a coastal gem known for its tourism and hospitality industry. Luxury resorts, vacation rentals, gourmet restaurants, high-end retail shops, and entertainment venues thrive within this bustling city. Miramar Beach's main attraction lies in its stunning white sand beaches along the Gulf of Mexico, providing endless opportunities for beach activities and water sports. Its boundaries extend into neighboring Okaloosa County, attracting a blend of permanent residents, vacation homeowners, and rental property occupants. Miramar Beach, including its neighboring areas, covers an estimated land area of around 4.7 square miles (12.2 square kilometers).

Continuing along the Gulf Coast, we encounter Santa Rosa Beach. This coastal community is renowned for its vibrant tourism industry, offering a plethora of accommodations ranging from upscale resorts to charming vacation rentals. Its demography reflects a mix of permanent residents, seasonal visitors, and individuals seeking a coastal lifestyle, resulting in a diverse and dynamic community. Santa Rosa Beach spans a larger area compared to other cities in Walton County, with an estimated land area of approximately 31.2 square miles (80.8 square kilometers).

A summary of the existing CRS classifications for the communities in the study area is is listed in **Error! Reference source not found.**. No cities in Walton County are listed in the FEMA Community Rating System Eligible Communities.

Table 1: Community Rating System for Walton County. Effective April 1, 2023.

Community #	Community Name	CRS Class Rating	Premium Discount for SFHA	% Discount for Non- SFHA	Status
120317	Walton County	6	20%	10	Cycle

Based on the 2014-2016 SFWMD Level 1 land use for Walton County, only 7.07% of the land use in the county is urban and built up, and water/wetlands makes up 29.16% of the land use. The majority of land is upland forest, with 48.3%, as shown in **Error! Reference source not found.**.

Table 2. Land use table for Walton County (2023 Florida Geographic Data Library (FGDL)).

Level 1 Land Use-Land Cover Type	Area (Acres)	Percentage of Total
Agriculture	52958.94669	7.17%
Barren Land	9242.05986	1.25%
Rangeland	40326.66002	5.46%
Transportation, Communication, and Utilities	11815.69287	1.60%
Upland Forest	356796.0541	48.30%
Urban and Built-Up	52194.79061	7.07%
Water	61593.80508	8.34%
Wetlands	153759.9055	20.82%
Total	**738687.9147**	**100.00%**

Walton County has a history of flooding and has implemented various measures for flooding mitigation over the years (see section 2.12 for more details). The County has experienced flooding primarily due to heavy rainfall events and proximity to large water bodies such as the Gulf of Mexico, Choctawhatchee Bay, and numerous rivers and creeks. The topography of the region, with low-lying areas in the coastal areas and wetlands, also contributes to flood vulnerability. The proximity to the ocean (Gulf of Mexico) makes the county vulnerable to sea level rise. Over the years, Walton County has faced multiple flooding incidents, including:

- March 1997: Heavy rainfall led to significant flooding throughout the county, resulting in property damage and road closures.
- April 2009: Intense storms caused widespread flooding, damaging homes and infrastructure and resulting in the declaration of a state of emergency.
- April 2014: Heavy rainfall caused severe flooding, leading to the evacuation of some residents and the closure of roads.

Today, the goal of a stormwater management system in many communities is to keep the community as a place to live and do business while limiting risk from damage due to flooding. The short-term impacts from stormwater include flooding in low-lying areas and standing water in areas with limited soil storage capacity. Less common, but of increasing frequency, is the potential for extensive inundation of some areas, especially low-lying areas, during periods with

high groundwater levels and groundwater impacted by sea level rise. As a result, there is a need to understand the economic impact of flooding events and to create cost-effective stormwater infrastructure and policy solutions to protect property. This means preserving as much property and economic activity as possible without disrupting current activity or expending funds on inappropriate projects with limited long-term or social value.

1.1 Surface Topography

Topography is a key parameter that influences many of the processes involved in flood risk assessment, and thus, up-to-date, high-resolution, high-accuracy elevation data are required. In order to meet the requirements for FEMA Risk Mapping, Assessment, and Planning (RiskMAP), 1-meter (2015 to present) and 1/9 arc-second (~ 3-meter) (2010 -2015) LiDAR DEMs were acquired. The 1 m × 1 m LiDAR tiles were kriged to create a topographic map of the study area (**Error! Reference source not found.**). This accuracy meets the 3DEP Quality Level 2 vertical root mean square error accuracy threshold of ±10 cm for FEMA (Arundel et al., 2015). The LiDAR used for this basin was 2016.

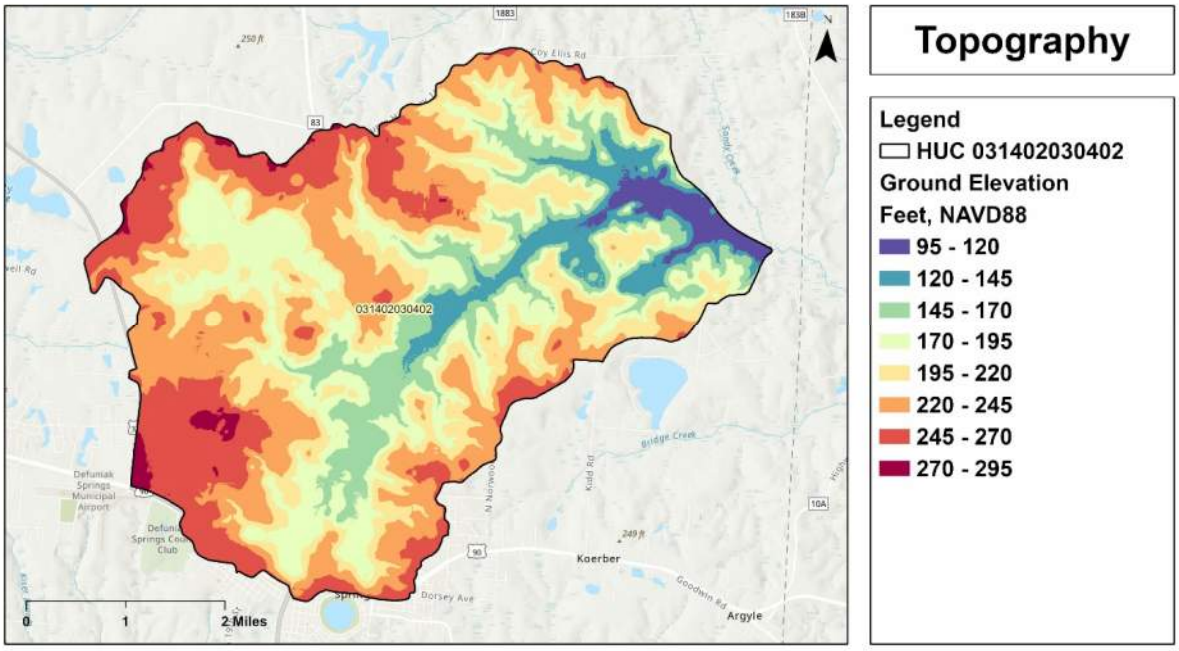

Figure 4. Topographic map of the HUC 031402030402 sub-watershed, processed by FAU

1.1.1 Geomorphological Considerations

Walton County's coastal area is characterized by the presence of barrier islands, extensive sandy beaches, and coastal dune systems. These features are influenced by the dynamic processes of wave action, tidal currents, and wind-driven sediment transport. The shoreline is subject to natural changes, including erosion and accretion, which significantly shape the coastal geomorphology.

Inland Walton County exhibits a mix of wetlands, forests, rolling hills, and rivers. These landforms are influenced by a combination of factors, including underlying geology, fluvial processes, and the region's hydrological regime.

Like many areas in Florida, Walton County is underlain by limestone formations. The specific composition and properties of these limestone formations in Walton County may vary. However, limestone is generally known for its porous nature, which allows for the absorption and storage of water. Underground aquifers within the limestone formations can hold significant volumes of freshwater, contributing to the region's water resources.

For context, the FIRM panel index of HUC 031402030402 sub-watershed is shown in **Error! Reference source not found.**.

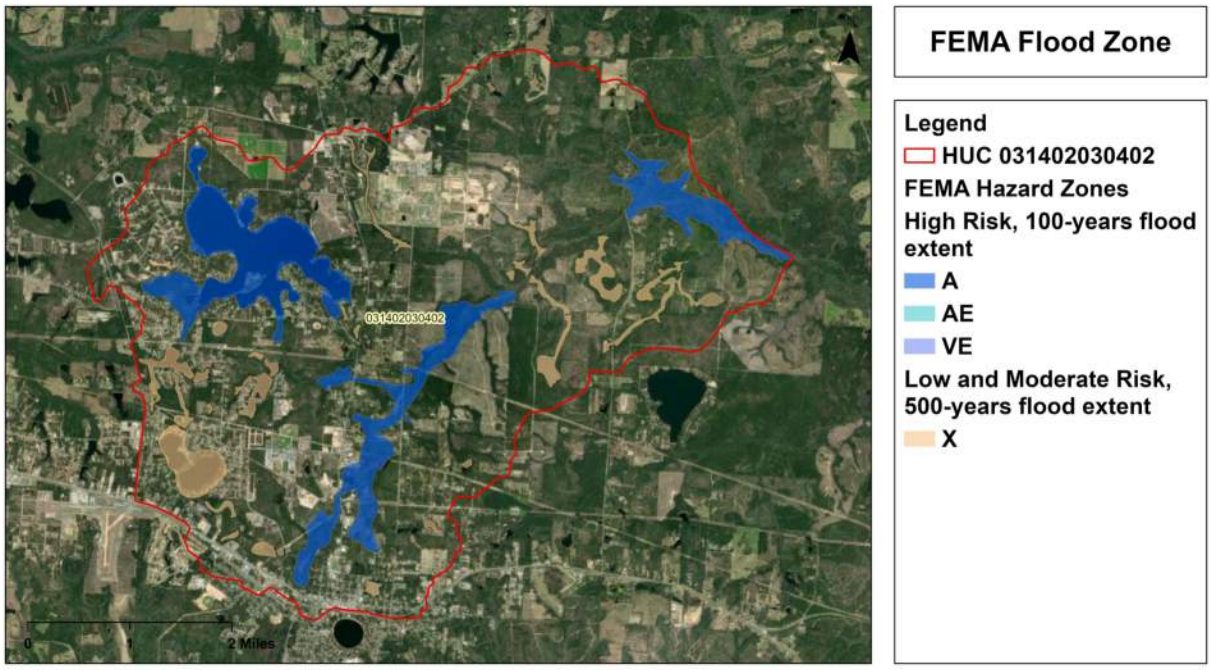

Figure 5. FEMA Flood Zone map (2020) for HUC 031402030402 sub-watershed, processed by FAU.

1.1.2 Waterway Features

In Walton County, Florida, the waterway features are primarily influenced by the presence of rivers, creeks, bayous, and the proximity to the Gulf of Mexico. To the south of Walton County lies the Gulf of Mexico. Sandy beaches, barrier islands, and the open waters of the Gulf itself characterize the coastline along the Gulf. The Gulf of Mexico influences the coastal processes, including wave action, tidal currents, and sediment transport along the shoreline. The combination between sea level rise and King tide would have detrimental consequences for the county costal

area, including the sub-watershed 031402030402 as it will reach the area thought Choctawhatchee Bay.

Walton County is home to several rivers and creeks that meander through its landscape. These waterways provide drainage for the inland areas and contribute to the overall hydrological system. Examples of significant rivers in the county include the Choctawhatchee River and the Shoal River. In addition, Walton County features bayous and estuaries that connect inland water systems to the Gulf of Mexico.

Choctawhatchee Bay serves as a vital estuarine ecosystem, where freshwater from rivers and creeks mixes with the saltwater from the Gulf of Mexico, serving as a vital estuarine ecosystem. This unique brackish water environment supports a rich diversity of flora and fauna, including various fish species, shellfish, migratory birds, and wetland vegetation, contributing to the overall biodiversity of the region. It also plays a significant role in the local economy of Walton County as it supports commercial and recreational fishing industries, providing livelihoods for local fishermen and contributing to the seafood industry, while also offering a range of recreational opportunities for residents and visitors alike, such as boating, kayaking, paddle boarding, and sailing. **Error! Reference source not found.** shows the bathymetry offshore.

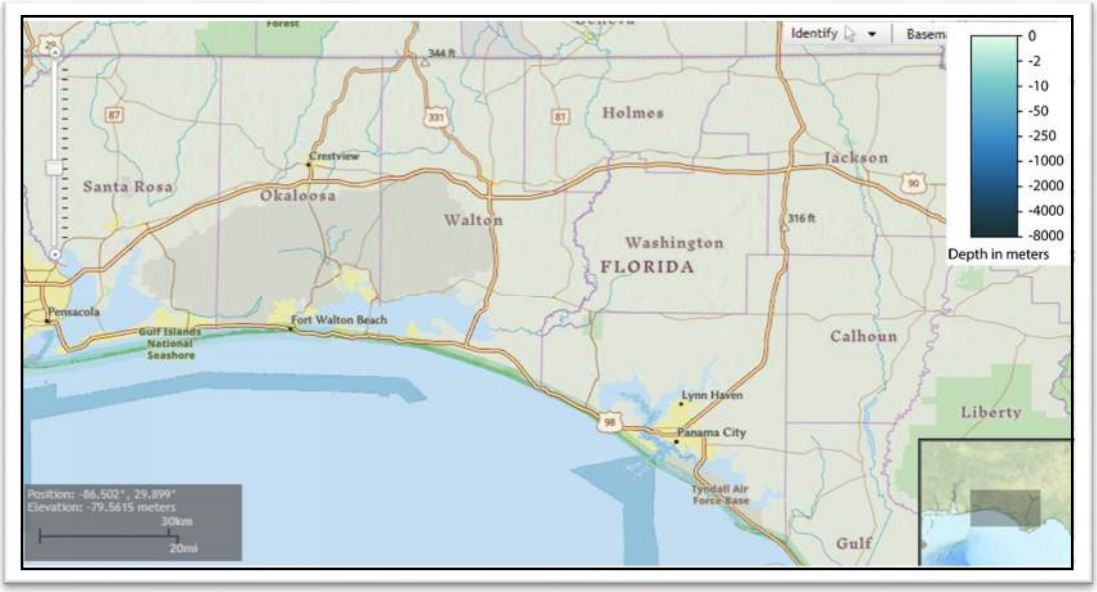

Figure 6. Bathymetry map of the shore of Walton County and surrounding counties of Florida Panhandle. Source: ncei.noaa.gov/maps/bathymetry/

Numerous tributaries exist throughout both the freshwater and estuarine portions of the watershed and can influence the overall hydrology of the area depending on rainfall and regional hydrological conditions. **Error! Reference source not found.** shows the location of all four surface water stations along with ground water stations (wells) and the drainage network of Walton County.

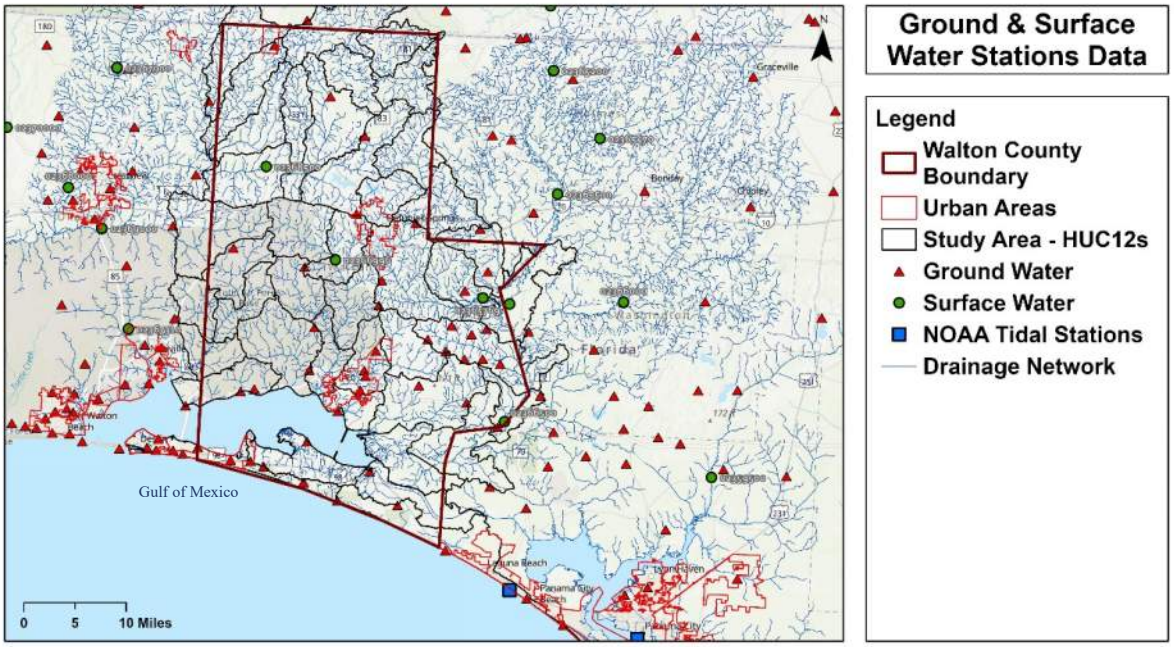

Figure 7. Ground & Surface Water Stations with drainage network for Walton County, processed by FAU.

1.1.3 Hydrologic Boundaries

The geographic area of the subject sub-watershed should be clearly defined to ensure that implementing the WMP will address all the major sources and causes of impairments and threats. Although there is no rigorous definition or delineation of this concept, one way to identify the geographic extent of the watershed master planning effort is to consult the United States Geological Survey (USGS) map of hydrologic units. A hydrologic unit is part of a watershed mapping classification system showing various areas of land that contribute surface water runoff to designated outlet points, such as lakes or stream segments. USGS designates drainage areas as sub-watersheds (including smaller drainages) numbered with 12-digit hydrologic unit codes (HUCs), nested within watersheds (10-digit HUCs). These are combined into larger drainage areas called subbasins (8 digits), basins (6 digits), and subregions (4 digits), which make up the large regional drainage basins (2 digits).

Region>>Subregion>>Basin>>Sub-basin>>Watershed>>Sub-watershed

The HUC 031402030402 has no major rivers and canals, but creeks, include:

- West Sandy Creek

- Andrews Mill Creek
- Poley Bran

Given that stream flow data are critical for estimating flooding, **Error! Reference source not found.** shows the historical streamflow during June 2022 to July 2023 for USGS 02366966. However, as there are only four surface water station within Walton County, it was necessary to use the nearest station to the sub-watershed 031402030402, which is USGS 02366966 Alaqua Creek Near Pleasant Ridge, FL.

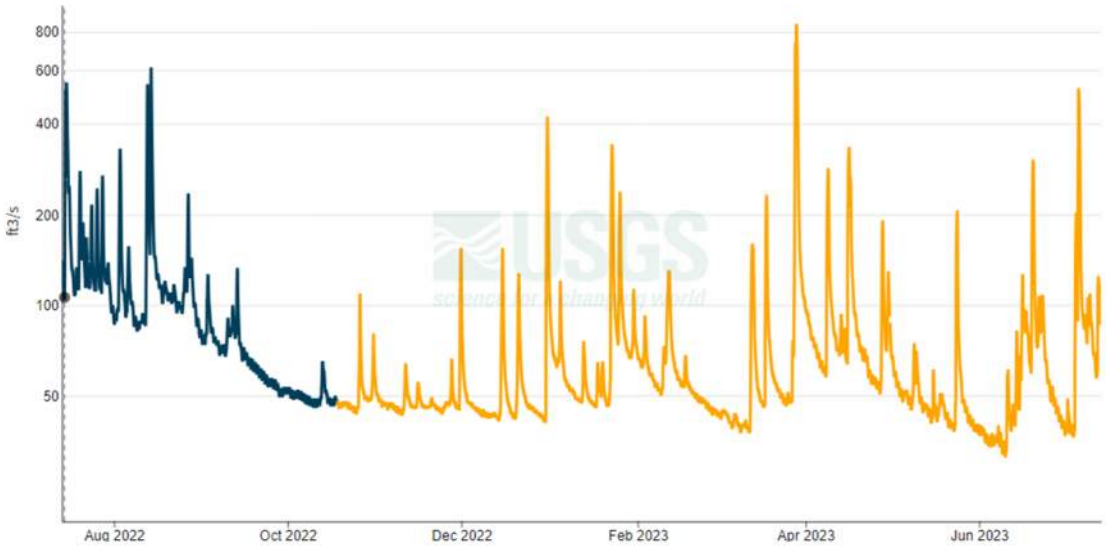

Figure 8. Average streamflow for Alaqua Creek Near Pleasant Ridge, FL (USGS 02366966 Surface-Water, June 2022 to July 2023).
Source: USGS Water Data Services (https://waterdata.usgs.gov/monitoring-location/02366996/#parameterCode=00065&period=P7D).

1.2 Groundwater

In this region of Florida, there is a direct interaction between groundwater and surface water. In addition to low land elevations and topographic relief, the groundwater and surface water are controlled by the canals, rivers, and tides. Since there is a limited number of groundwater monitoring stations, the strong relationship between groundwater and surface water was leveraged to develop a 99th- percentile surface of the water table elevation for mapping purposes. To establish a common date for modeling, the recorded groundwater table elevations were sorted in ascending order to determine the 98th - 100th percentile date of occurrence in Excel®, following the procedure detailed in Romah (2011). This procedure was automated for this effort using a python code to process the groundwater data more efficiently. Outliers and anomalous groundwater levels in the database are initially identified (e.g. catastrophic storm events) and replaced by region-specific mean values based on observations available from the nearest well. Missing date-specific data are estimated using simple temporal interpolation based on observations available in time. If a station

(or monitoring well) data contains large amounts of missing data, it is not used in the generation of the groundwater surface.

In Walton County, the average annual rainfall is abundant, reaching 65 inches at DeFuniak Springs. This rainfall predominantly infiltrates the sand-and-gravel aquifer and eventually seeps into streams or the underlying artesian Floridan aquifer. The county's two major aquifers are the sand-and-gravel aquifer and the Floridan aquifer. While the sand-and-gravel aquifer provides water for rural domestic use and plays a crucial role in water storage and streamflow maintenance, it also serves as a recharge source for the Floridan aquifer. Water from the sand-and-gravel aquifer contains varying levels of dissolved solids, pH, and iron content. The Floridan aquifer, being the primary water supply source, underlies the entire county and yields around 500 to 1,000 gallons per minute from wells, except along the Gulf Coast where the permeability is lower. Recharged by leakage from the sand-and-gravel aquifer, the Floridan aquifer's movement is predominantly southward away from the potentiometric high in northwestern Walton County. It discharges through springs, seeps along the Choctawhatchee River, and by wells. In southern Alabama, the Floridan aquifer is directly recharged by rainfall when it is exposed or close to the land surface. (Bureau of Ecology, 1974).

Once a common time period is determined across the majority of shallow groundwater wells, canal data can be gathered for that common date (and two days prior, in the event the canals were deliberately lowered). Data was obtained from the NWFWMD and processed by FAU at cwr3.fau.edu. Between stations, an ArcGIS tool permits a line to be drawn to replicate the rivers and streams to establish points for a gradient between stations. The same is true for the ocean, but it is a constant head boundary. The topography and points where streams join form boundary conditions for the screening tool on the edges of the basin and affect localized groundwater. The tide issue is resolved by using the common date for high tide.

Error! Reference source not found. shows the drainage network of HUC 031402030402 and points out the location of the ground water station in the surroundings. A groundwater-surface layer for the HUC 031402030402 sub-watershed was created using several datasets including water level data from USGS and NWFWMD and groundwater elevation contour maps. The datasets were used to generate a raster surface of the groundwater elevation (**Error! Reference source not found.**).

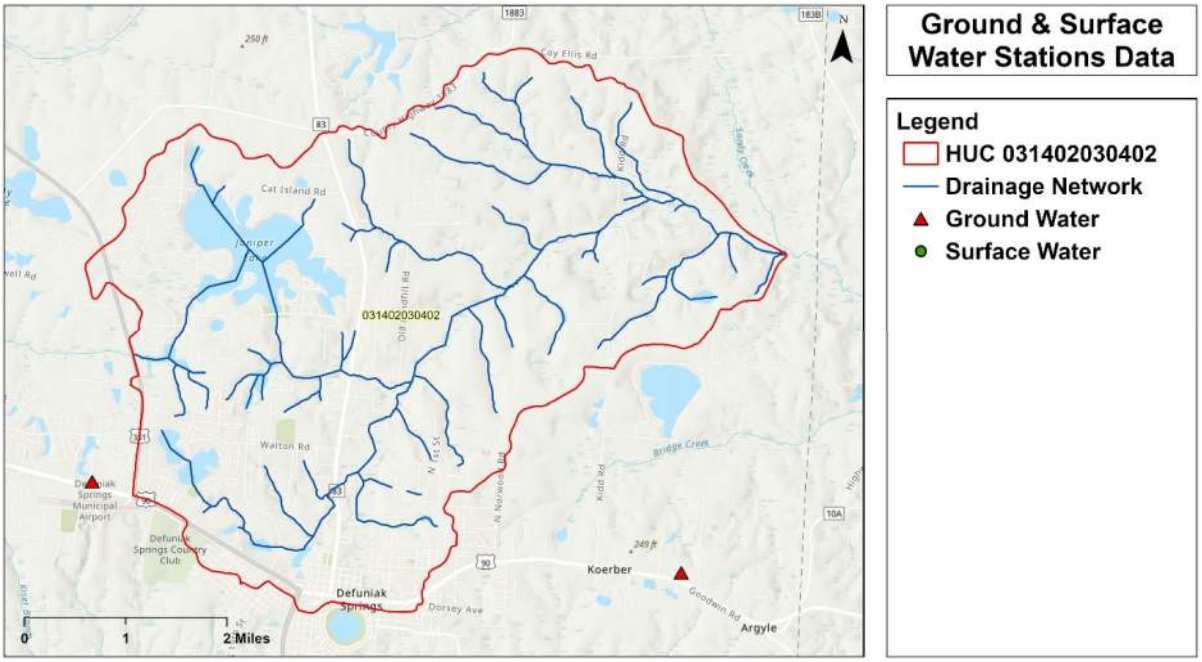

Figure 9. Ground and Surface Water Stations in the HUC 031402030402 sub-watershed, processed by FAU.

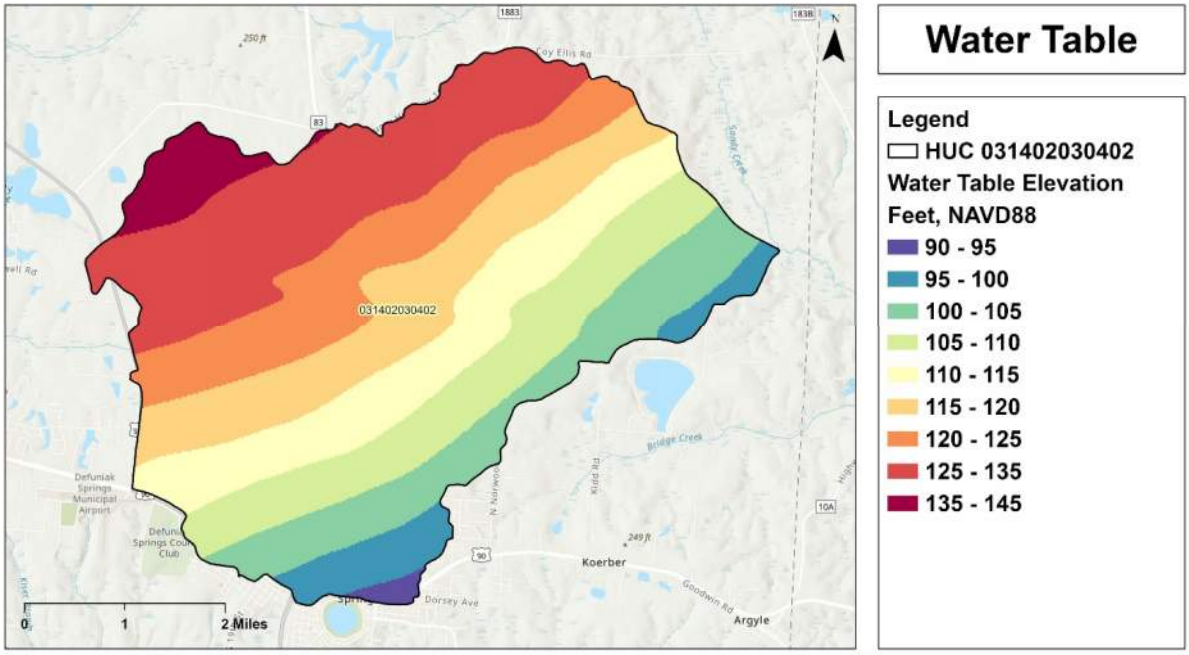

Figure 10. Elevation of the top of the surface groundwater layer for the HUC 031402030402 sub-watershed, created by multiple linear regression analysis – elevation NAVD88, processed by FAU.

1.3 Surface Water/Tides

Historically, surface water and tides have been an important factor in determining how much freshwater is delivered, how fast this water enters wetlands and estuaries, and the quality of that water. Evapotranspiration and rainfall do not coincide in the study area, which makes water supply planning difficult. **Error! Reference source not found.** shows the observed rainfall over Walton County for every month between 1900 and 2023 - each rectangle is a month and each column is a year. The 12-month total precipitation decreased 7.5 inches from May 1900 to April 2023. From May 1900 to April 2023, the average 12-month total precipitation was 60.5 inches, for the entire county.

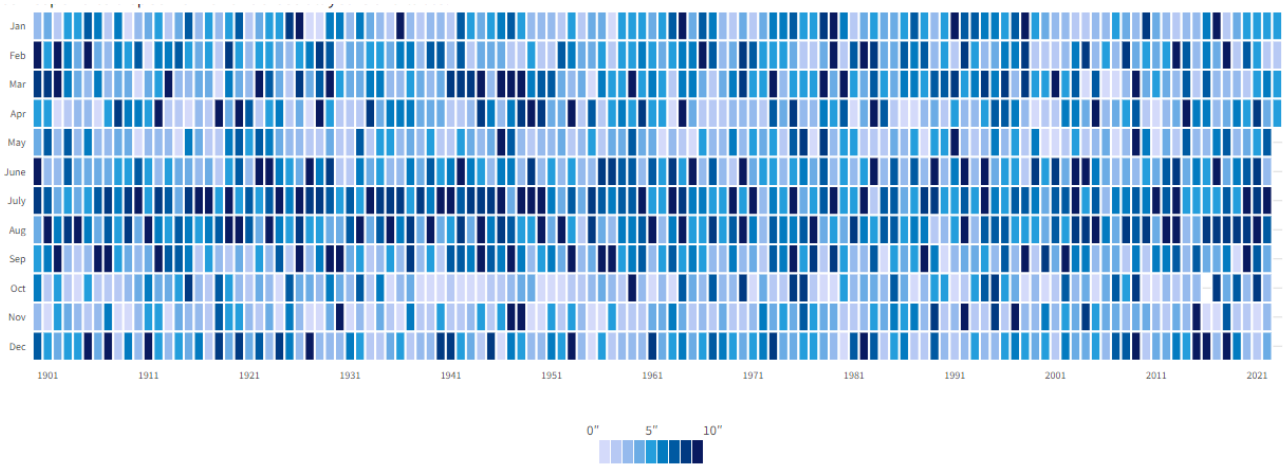

Figure 11. Monthly precipitation in Walton County, FL.
Source: National Centers for Environmental Information
(https://usafacts.org/issues/climate/state/florida/county/walton-county/#precipitation/).

While the topography (Section 1.1) and native soil (Section 1.4) create an environment that is highly permeable and capable of infiltrating significant percolation into the soil, changes in land use and land cover have resulted in water falling on impervious areas, where the water collects in pools or runs off rapidly, in direct contrast to the natural condition. This runoff flowing over impermeable regions can lead to larger scale flooding.

Tidal data can be gathered from NOAA tidal gages and other gages monitored by local governments. The location of tide gages is important to ensure they accurately depict tides, as opposed to inland waters. To set a boundary for the coastal areas, the high tide on the common date from 12/03/2018 to 12/10/2018 was selected. **Error! Reference source not found.** shows the two closest tide stations to Walton County. Since there is no NOAA tide station in Walton County, the Panama City Beach station (8729210) was used.

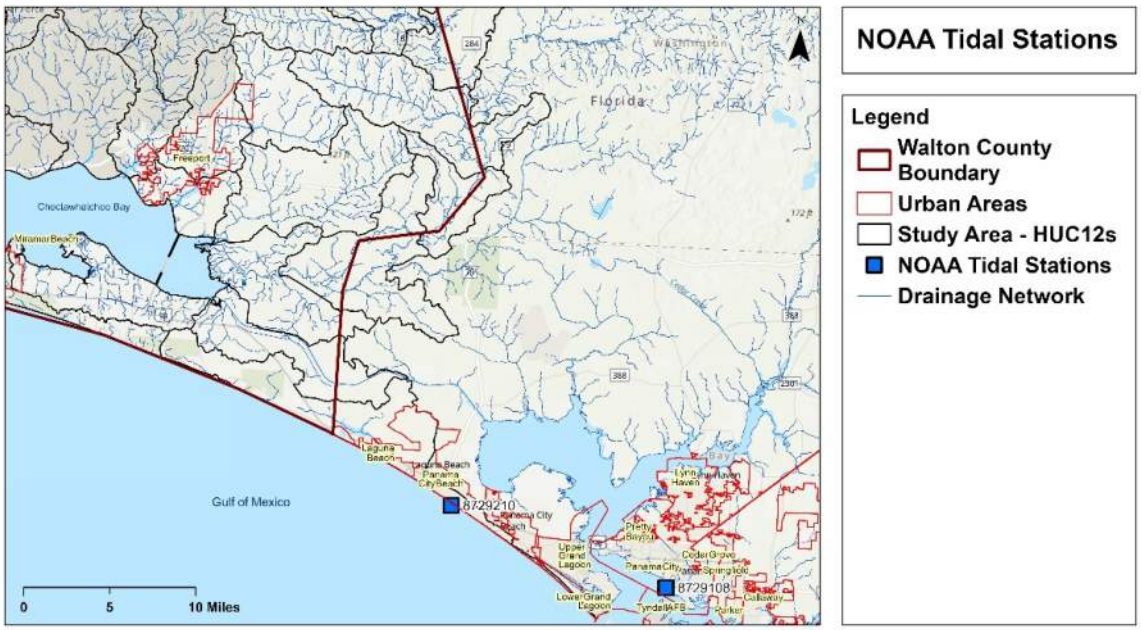

Figure 12. Locations of Florida tidal stations maintained by NOAA near to Walton County, processed by FAU.

1.4 Soils

Soil can store water if there is adequate distance between the topographic surface and the groundwater, and the soil types are capable of absorbing the water. Soil storage capacity is the volume of soil pores in the unsaturated zone that is available to store infiltrated stormwater (Gregory et al., 1998). Throughout Florida, it is common to have large volume storm events that fill the voids in the unsaturated zone as shown in **Error! Reference source not found.**.

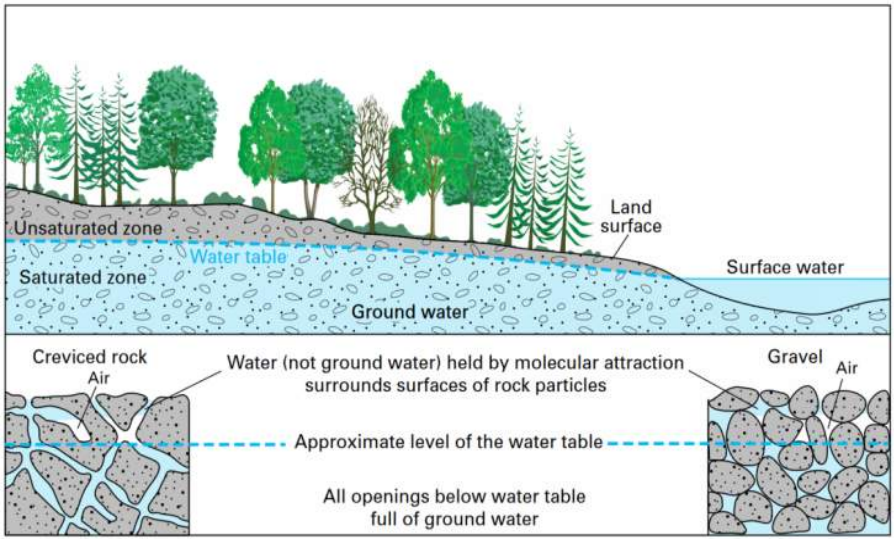

Figure 13. Zones where underground water exists.
Source: USGS, 2020.

The unsaturated zone is the portion of the subsurface above the water table that contains soil/rock and air and water in its pores as shown in **Error! Reference source not found.**. This zone affects the rate at which the aquifer is recharged by controlling water movement from the surface of the land downward towards the aquifer. During rain events, the soil voids fill up quickly resulting in the water table rising to the surface, and the surplus rainfall becomes runoff.

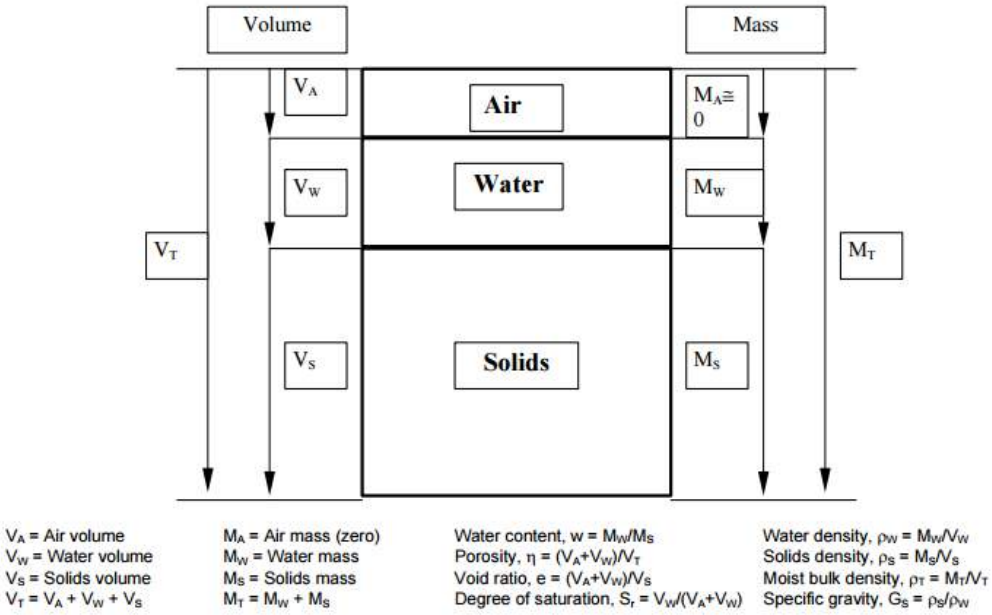

Figure 14. Saturated zone soil phase diagram and definitions.
Source: Gregory et al., 1998.

Soil data is available from the United States Department of Agriculture (USDA) or other agencies in the form of maps that can be incorporated as a GIS layer. The Gridded SSURGO (gSSURGO) dataset from USDA is chosen. This dataset is similar to the standard product from USDA Natural Resources Conservation Service (NRCS) Soil Survey Geographic (SSURGO) database, but is in the Environmental Systems Research Institute, Inc. (ESRI®) file geodatabase format. A file geodatabase allows for statewide or even Conterminous United States (CONUS) tiling of data. The gSSURGO dataset contains all of the original soil attribute tables in SSURGO. All spatial data are stored within the geodatabase instead of externally as separate shape files. Both SSURGO and gSSURGO are considered products of the National Cooperative Soil Survey (NCSS). Figure 15 shows the unsaturated zone found by the difference between the groundwater elevation layer and surface topography.

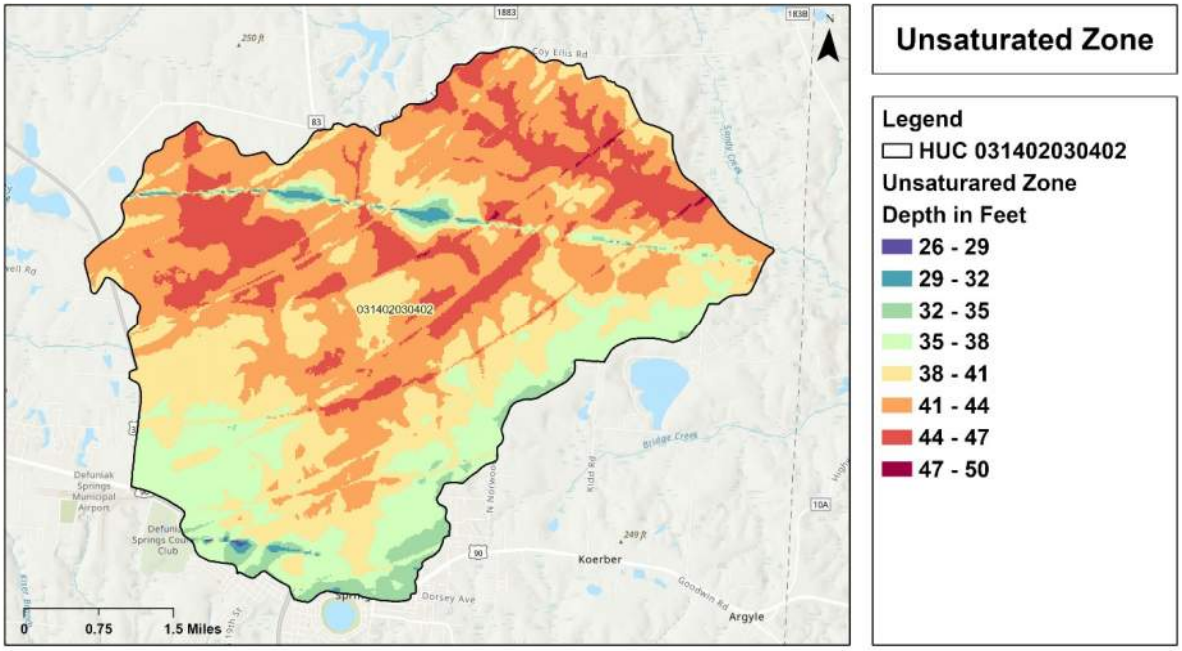

Figure 15. Unsaturated zone map for HUC 031402030402, processed by FAU.

The available water storage from USDA derived for the soil layer (0-150 cm or 0-5 ft) statewide is shown in **Error! Reference source not found.**, which covers most of Florida with a spatial resolution of 10 m. The unit is in cm. As a result of applying this layer to the study area (**Error! Reference source not found.**), the estimated soil storage capacity can be illustrated. A significant portion of the basin demonstrates a moderately favorable soil storage capacity, falling within the range of 35 to 47 feet of remaining capacity.

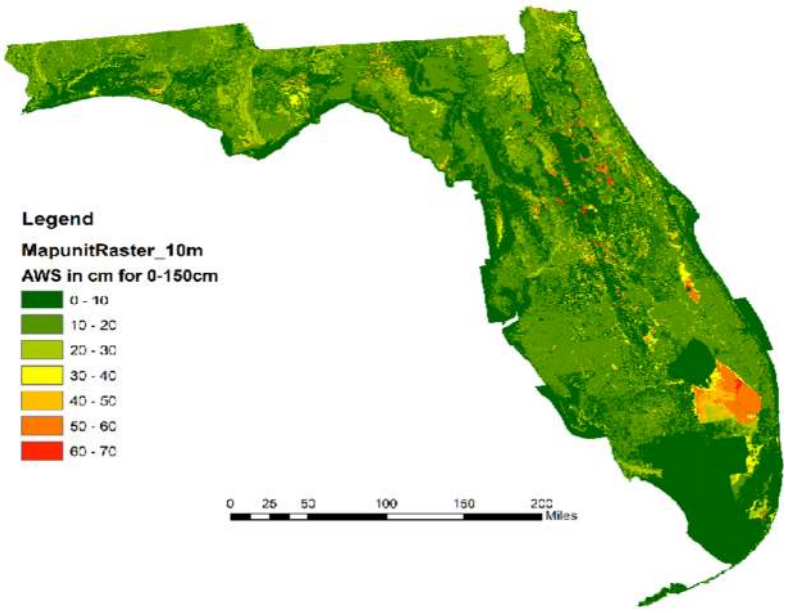

Figure 16. Available water storage derived from the gSSURGO soil database for all of Florida, as processed by FAU.

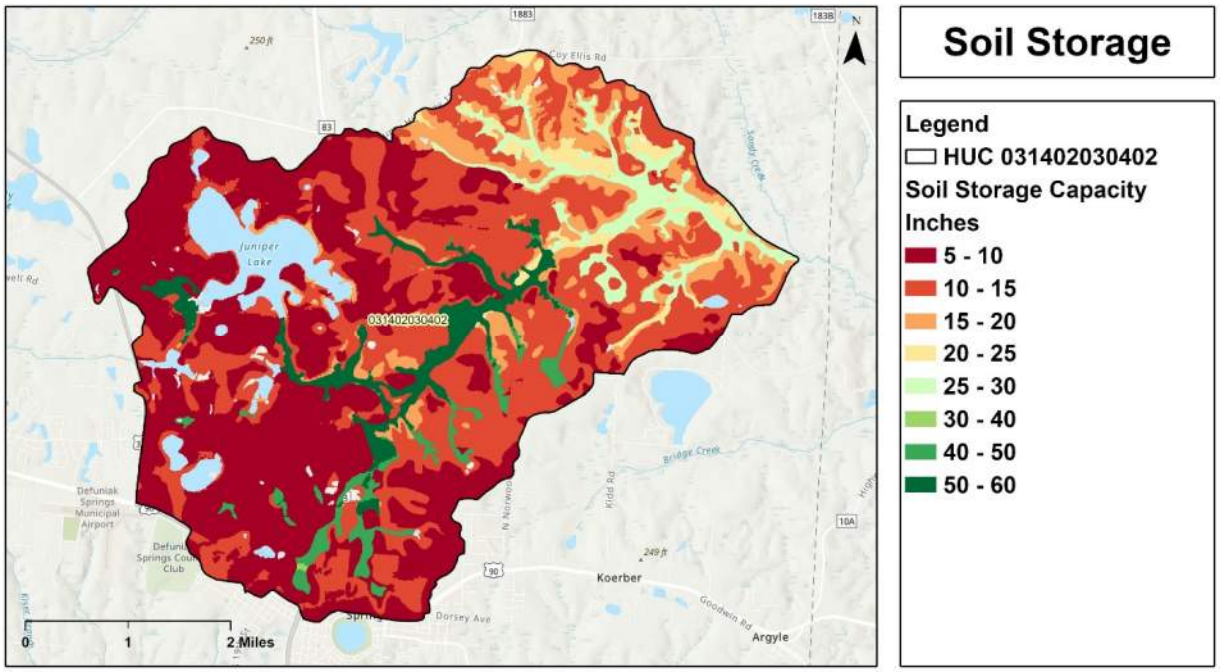

Figure 17. Water storage capacity of soil for the HUC 031402030402, processed by FAU.

Lastly, **Error! Reference source not found.** shows the water holding capacity for the basin, which refers to the capacity of a particular soil texture to retain water against the force of gravity.

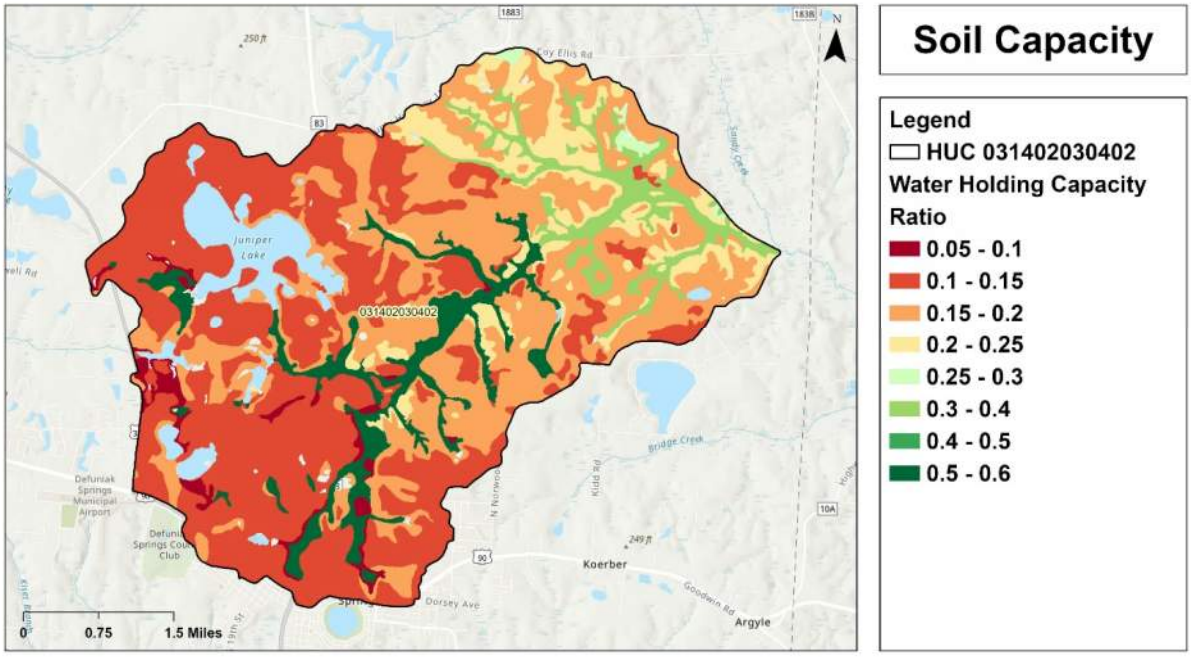

Figure 18. Water Holding Capacity (ratio) for the HUC 031402030402, processed by FAU.

1.5 Land Cover

The USGS produces the NLCD of nationwide data on land cover at a 30-m resolution with a 16-class legend based on a modified Anderson Level II classification system. NLCD is coordinated through the 10-member Multi-Resolution Land Characteristics Consortium (MRLC) to provide digital land cover information nationwide. For the conterminous United States, NLCD 2016 contains 28 different land cover products characterizing land cover and land cover change across 7 epochs from 2001-2016, urban imperviousness and urban imperviousness change across 4 epochs from 2001-2016, tree canopy and tree canopy change across 2 epochs from 2011-2016 and western U.S. shrub and grassland areas for 2016 (**Error! Reference source not found.**).

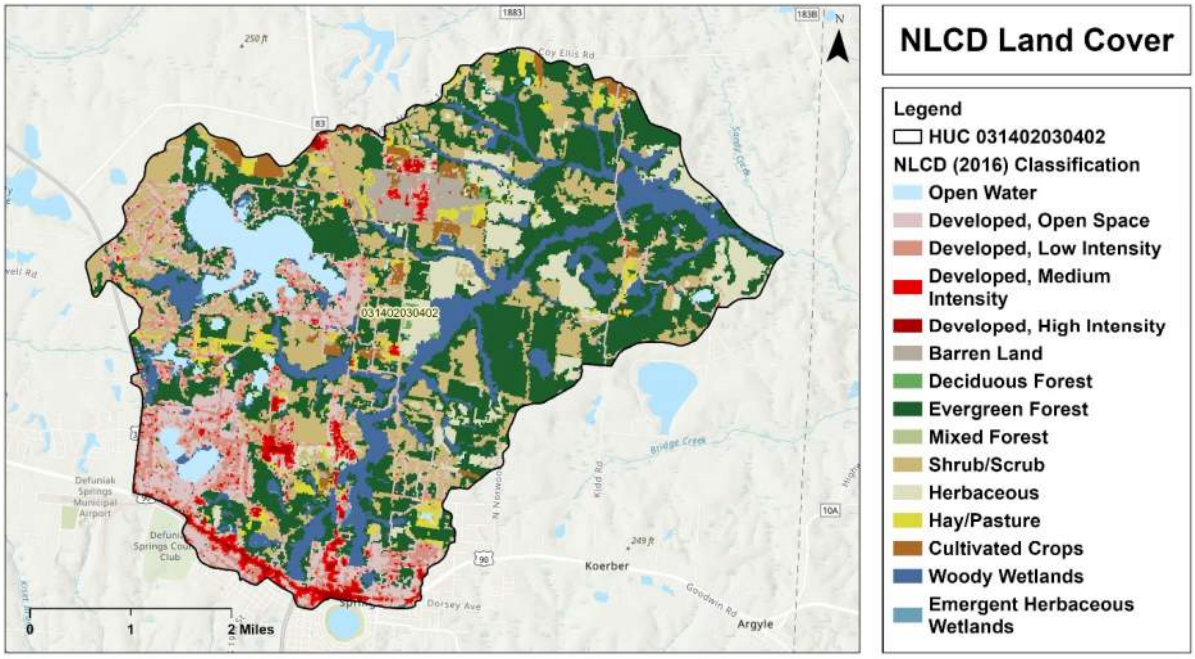

Figure 19. Land use in the HUC 031402030402 (from the NLCD 2016 database), processed by FAU.

The dataset is derived from the Florida Land Use Cover Classification System (FLUCCS), which is digitized by photo-interpretation on county-based aerial photography with varying resolution in the range of 4 in - 2 ft pixel. The NLCD2016 has a 30-meter resolution derived from Landsat imagery. Hence, the NLCD maps appear much coarser and pixelated compared to the 2023 Florida Geographic Data Library (FGDL) (https://fgdl.org/fgdlmap/) maps. A view of the latter is provided in **Error! Reference source not found.**. The future land use maps need to be used for the final land cover, as adjusted for future stormwater improvements set by regulatory standards.

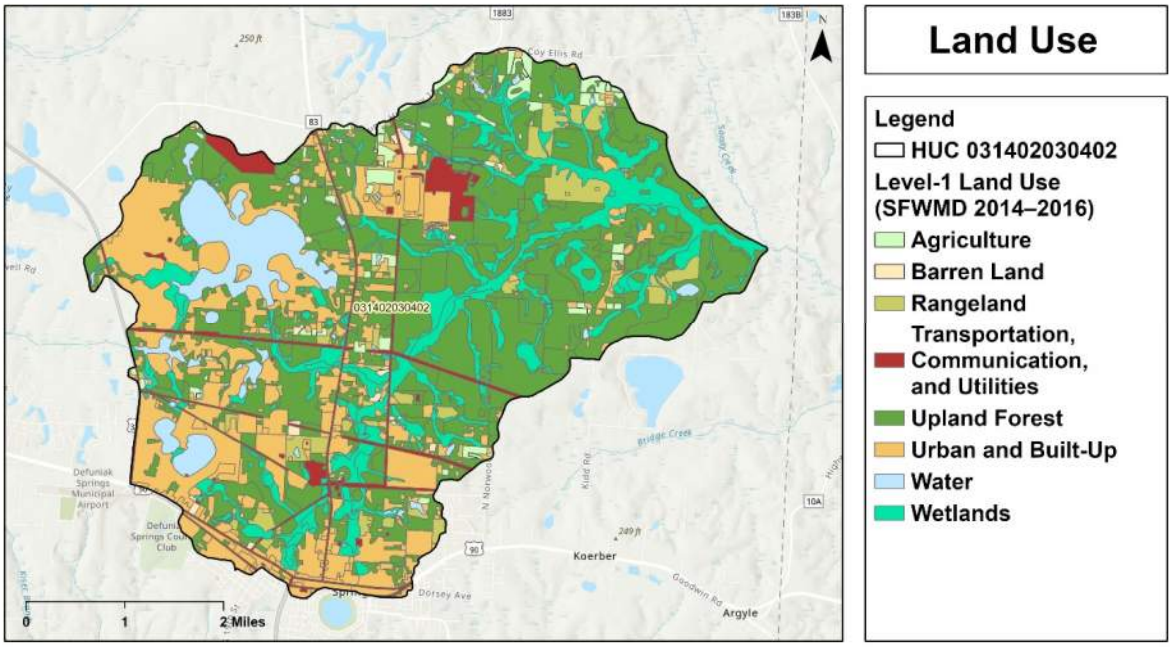

Figure 20. Land use in the HUC 031402030402 (2023 Florida Geographic Data Library (FGDL)), processed by FAU.

In the HUC 031402030402 sub-watershed, the predominant land cover is upland forest, accounting for 35.85% of the area, followed by wetlands that comes in second with 19.55%. Developed land constitutes also a great portion of the basin, with 18.97% categorized as urban and built-up, and 16.26 % as Transportation, Communication, and Utilities, once the basin takes a small portion of the city DeFuniak Springs. The percentage of area by land use type is as shown in **Error! Reference source not found.**. **Error! Reference source not found.** shows the roughness of the surface.

Table 3. Land use for HUC 031402030402 subwatershed (2023 Florida Geographic Data Library (FGDL)).

Level 1 Land Use Land Cover Type	Area (Acres)	Percentage of Total
Agriculture	488.95	2.17%
Barren Land	84.63	0.38%
Rangeland	651.63	2.89%
Transportation, Communication, and Utilities	3667.31	16.26%
Upland Forest	8084.01	35.85%
Urban and Built-Up	4279.27	18.97%
Water	886.65	3.93%
Wetlands	4409.95	19.55%
Grand Total:	**22552.40**	**100.00%**

Table 4. Roughness and CN Values for Each Land Use Code.

DOR Code	Use	Impervious %	Roughness
0	Vacant	0	0.4
1	Single Family	29	0.25
2	Mobile homes	21	0.05
4	Condos	60	0.05
7	Vacant –to be developed	0	0.4
8	Multifamily	60	0.05
TH 101	Townhomes	91	0.025
94	Road Right-of-Ways	50	0.08
	Open water	100	n/a
All others	Commercial, etc.	50	0.07

1.6 Precipitation

Rainfall used in the screening tool is based on the SFWMD 3-day 25-year storm, but can be modified for any rainfall event using the accumulated rainfall table obtained from NOAA Atlas 14 Point Precipitation Frequency Estimates (https://hdsc.nws.noaa.gov/hdsc/pfds/pfds_map_cont.html). Figure 21 shows the 3-day 25-year rainfall map based on the NOAA Atlas 14 dataset for the whole state. **Error! Reference source not found.** to **Error! Reference source not found.** rainfall 1-day 100-year, 1-day 10-year, and 1-day 5-year storm event scenarios, in inches.

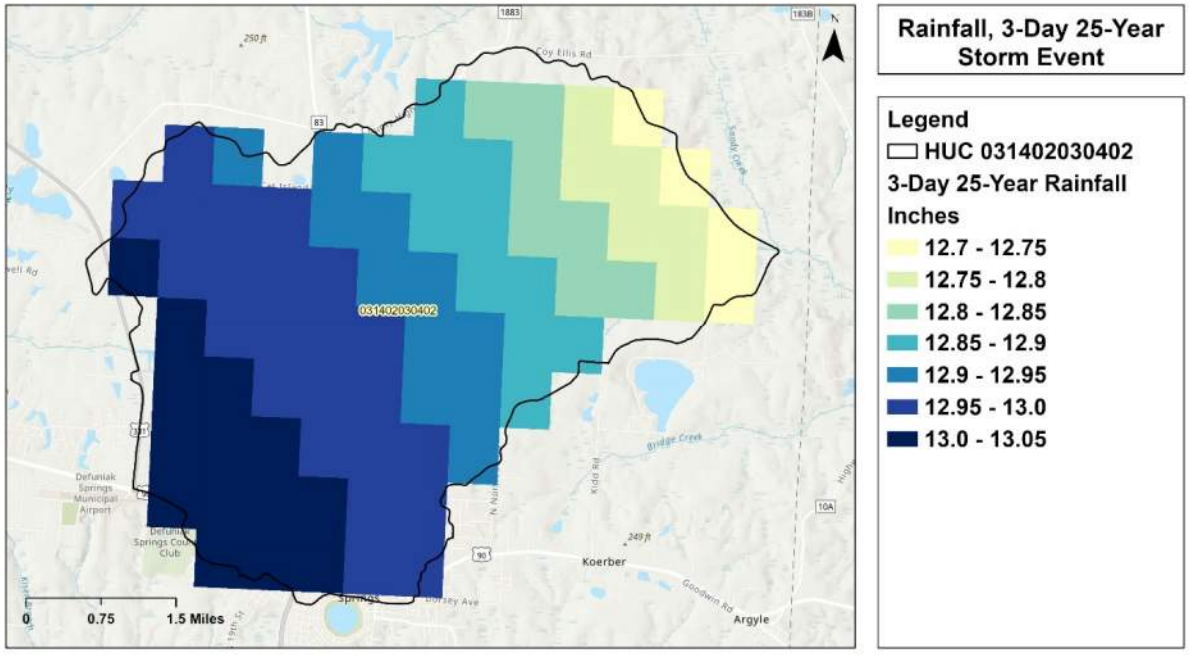

Figure 21. Rainfall distribution map across HUC 031402030402 sub-watershed, for 3-day 25-year storm event, processed by FAU.

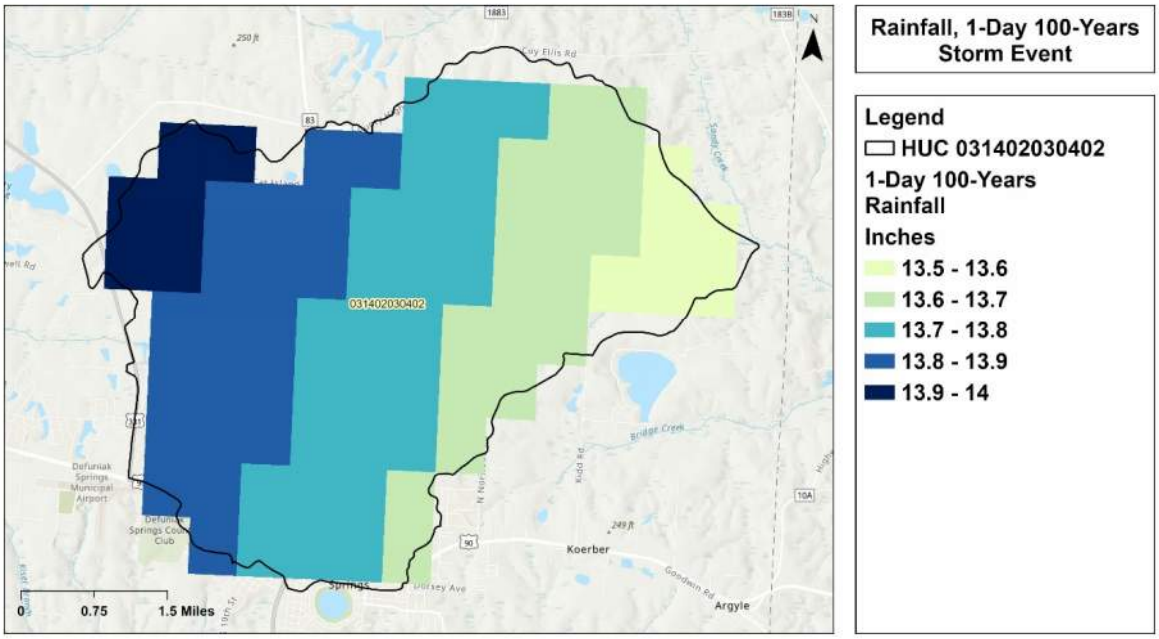

Figure 22. Rainfall distribution map across HUC 031402030402 sub-watershed, for 1-day 100-year storm event, processed by FAU.

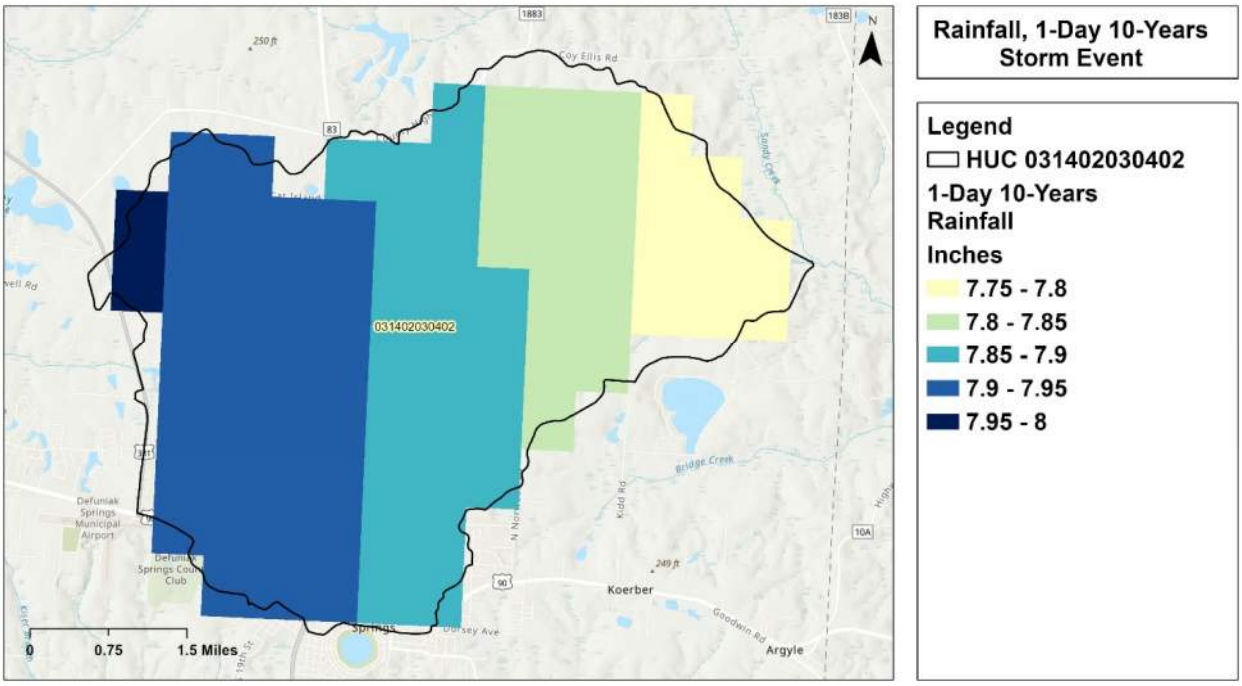

Figure 23. Rainfall distribution map across HUC 031402030402 sub-watershed, for 1-day 10-year storm event, processed by FAU.

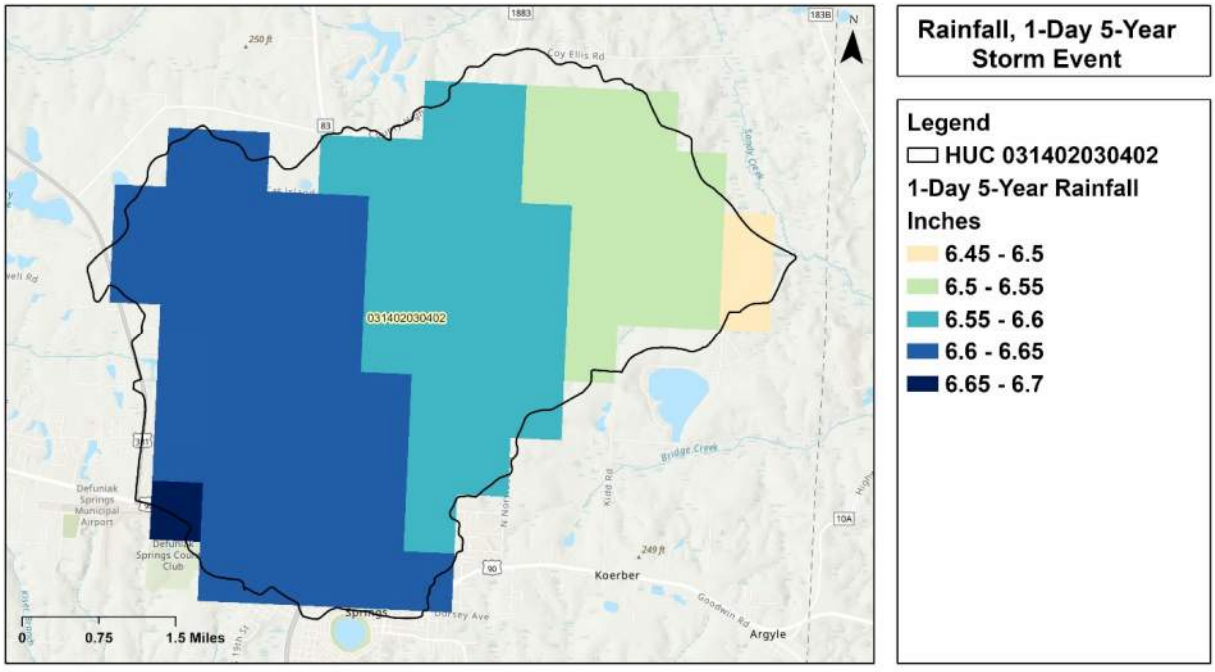

Figure 24. Rainfall distribution map across HUC 031402030402 sub-watershed, for 1-day 5-year storm event, processed by FAU.

1.7 Open Space

Open space is defined as areas that are exempted from development. Generally, this means one or more of the following qualifiers exist:

1. Land that is valuable for recreation, forestry, fishing, or conservation of wildlife or natural resources
2. Land that is a prime natural feature of the state's landscape, such as a shoreline or ridgeline
3. Land that is habitat for native plant or animal species listed as threatened, endangered, or of special concern
4. Land that is a relatively undisturbed example of an uncommon native ecological community
5. Land that is important for enhancing and conserving the water quality of lakes, rivers, and coastal water
6. Land that is valuable for preserving local agricultural heritage
7. Proximity to urban areas or areas with open space deficiencies and underserved populations
8. Vulnerability of land to development
9. Stewardship needs and management constraints
10. Preservation of forest land and water bodies that naturally absorb significant amounts of carbon dioxide

Permanent protection of sensitive areas can provide critical water quality protection and can be achieved through partnerships with landowners, municipalities, land trusts and state agencies. There is limited land in the study area that has been protected via acquisition by federal, state or local agencies, has conservation easements or is designated as wetlands or areas of critical concern. Agricultural land and other land cover will come from the land cover map (in Section 1.5). Added to this will be the water bodies discussed in Section 1.9, whi1ch serve a related condition to open space.

1.8 Impervious Areas

Impervious areas do not permit the infiltration of rainfall to groundwater, and because the water cannot infiltrate, it runs off faster. Faster runoff means that flows to water bodies and storm sewers occur faster and with higher peaks. The result is a disruption of the natural and potentially the planned hydrology. Impervious areas include pavement, buildings, and other areas that reduce runoff capacity. In other words, developed areas have much higher imperviousness than open spaces that are natural or agricultural.

The NLCD provides nationwide data on land cover and land cover change at a 30-m resolution with a 16-class legend based on a modified Anderson Level II classification system. Systematically

aligned over time, the database offers the ability to understand both current and historical land cover and land cover change to enable assessment of trends. Using the NLCD 2016 dataset, a layer was created by using only three categories out of the 13 to identify impervious areas such as primary roads in urban areas, secondary roads in urban areas, and tertiary roads in urban areas. The new layer was then converted to match the 3-meter spatial resolution from the DEM and the standard State Plane Coordinate system. **Error! Reference source not found.** shows the impervious areas derived from the NLCD 2016 as updated by the future land use map.

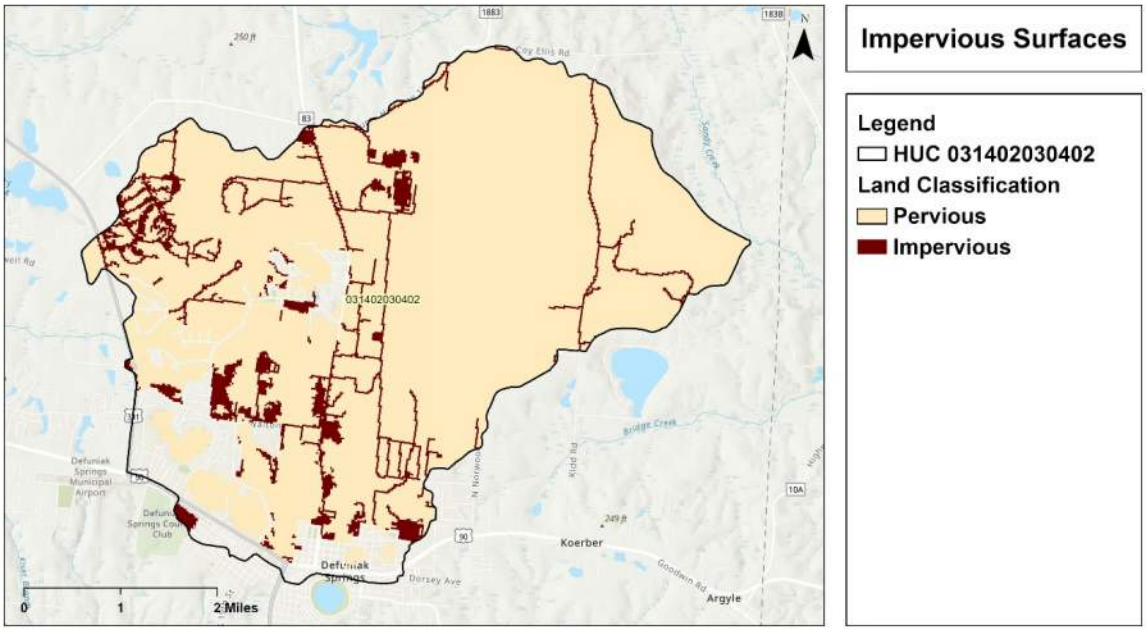

Figure 25. Impervious area map for the HUC 031402030402 sub-watershed, processed by FAU.

1.9 Water bodies

Water bodies were defined in the statewide land use land cover dataset to set soil water holding capacity to zero in model simulations (**Error! Reference source not found.**). Note that tiny water bodies may be missing from the maps. Soils were discussed previously in Section 2.4.

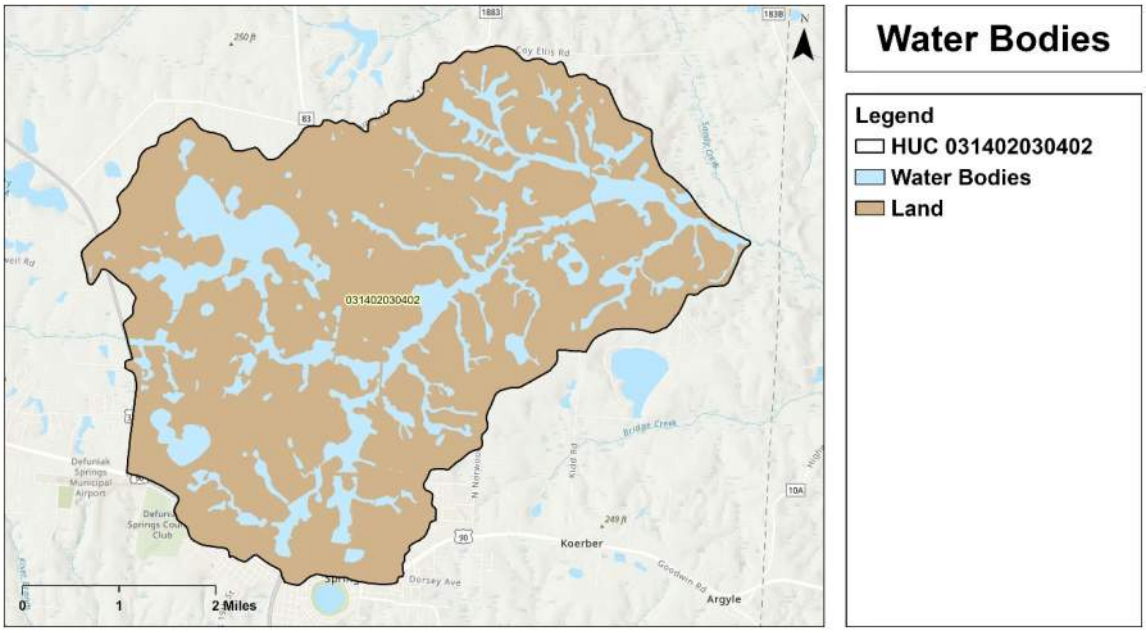

Figure 26. Water bodies map for the HUC 031402030402 sub-watershed, processed by FAU.

1.10. Natural Resources

Understanding the study area's natural resources is critical to identifying potential sources of water quality degradation and areas to designate for conservation, protection, and restoration. One possible goal of watershed master planning is to protect terrestrial wildlife, aquatic habitat, and buffer zones. USGS maintains important sources of information on physical and geographical features as well as soil and mineral resources, surface and ground water resources, topographic maps, and water quality monitoring data. The USDA's Natural Resources Inventory (NRI) (www.nrcs.usda.gov/technical/NRI) is a survey of information on natural resources on non-federal land in the United States that captures data on land cover and land use, soil erosion, prime farmland soils, wetlands, habitat diversity, erosion, conservation practices, and related items. Since 2001, the NRI has been updated continually with annual releases of NRI data from all 50 states. The information provided can be used for addressing agricultural and environmental issues down to the county or cataloging unit level. Therefore, this data can be used to determine erosion and site-specific soil characteristics for certain land uses such as croplands, pasturelands, forestlands, etc., but the data is typically provided as inventories, not GIS layers.

1.11 Demographics

Demographics data is important for determining several key indicators for watershed master planning such as the ability to pay for improvements, social justice issues, land acquisition costs, property/land use, and communication strategies. The US Census has databases at the census tract

level. Based on the census data for the study area, **Error! Reference source not found.** outlines population and racial composition demographics.

Table 5. Demographics and Housing Characteristics of Cities and Towns in Walton County.

Demographic Parameter	**Miramar Beach**	**Freeport**	**DeFuniak Springs, City**	**Paxton**	**Rosemary Beach**	**Santa Rosa Beach***	**Walton County**
Type	CDP**	City	City - County Seat	Town	Unincorporated community		County

*It includes the communities of Point Washington to the East and a 15-mile stretch of the Emerald Coast from the east side of Miramar Beach to the west side of Seagrove Beach and the beach communities along 30A, including Grayton Beach and Seaside.
** Census Designated Place.

1.12 Stormwater Infrastructure Inventory

Local community stormwater systems consist of drainage ditches, storm sewers, retention ponds and other facilities constructed to store runoff or carry it to a receiving stream, lake, ocean, or other waterbody. Other man-made features include yards and swales that collect runoff and direct it to the sewers and ditches. When most of these systems were built, they were typically designed to handle the amount of water expected during a 10-year storm. Larger storms overload them, and the resulting backed-up sewers and overloaded ditches produce shallow flooding. Another urban drainage problem occurs in the areas protected by levees. Being in floodplains, they are flat and do not drain naturally, especially when a levee blocks the flow to the river. To drain these areas, channels have been built and pumps installed to mechanically move the water past the levee. Often, these man-made systems do not have the capacity to handle heavy rains or intense storms.

Another challenge with stormwater infrastructure is related to recordkeeping. It is not uncommon for stormwater data to be incomplete in most jurisdictions and completely lacking in others. Quality of data differs from jurisdiction to jurisdiction; some are in GIS formats, while others are paper maps or as-builts that represent the infrastructure at a macroscale level. The condition of the assets may be lacking, and the maintenance history may not be available either. Stormwater assets may have been installed with no records, especially in rural areas, farm fields, and private property.

Walton County passed Ordinance No. 2008-06 that prohibits unauthorized discharges into storm drains or ditch systems. In addition, the Public Works Division is currently running a continuous public awareness campaign aimed at encouraging the adoption of best management practices (BMPs) for managing stormwater runoff. This initiative targets both the business community and the residents of Walton County.

To address the issue of flooding, Walton County has implemented several measures along the years, such as:

- Drainage Systems: The county has invested in the development and maintenance of drainage systems, including ditches, canals, and retention ponds, to manage stormwater runoff and reduce flood risk.
- Floodplain Management: Walton County has adopted floodplain management regulations and participates in the National Flood Insurance Program (NFIP) to encourage responsible development in flood-prone areas.
- Elevation Standards: New construction projects within flood zones are required to adhere to specific elevation standards to minimize potential flood damage.
- Emergency Response: The county has established emergency response plans to assist residents during flood events, including evacuation procedures and the provision of emergency shelters.

Key stormwater assets for the HUC and Walton County are indicated in **Error! Reference source not found.** and **Error! Reference source not found.**, respectively. Stormwater structures and management processes in the county consist of stormwater outfall, water wells, weir, pollutant control boxes, inlets catch basins, pipes culverts, ditch conveyance swales, structures, pipes and open conveyance.

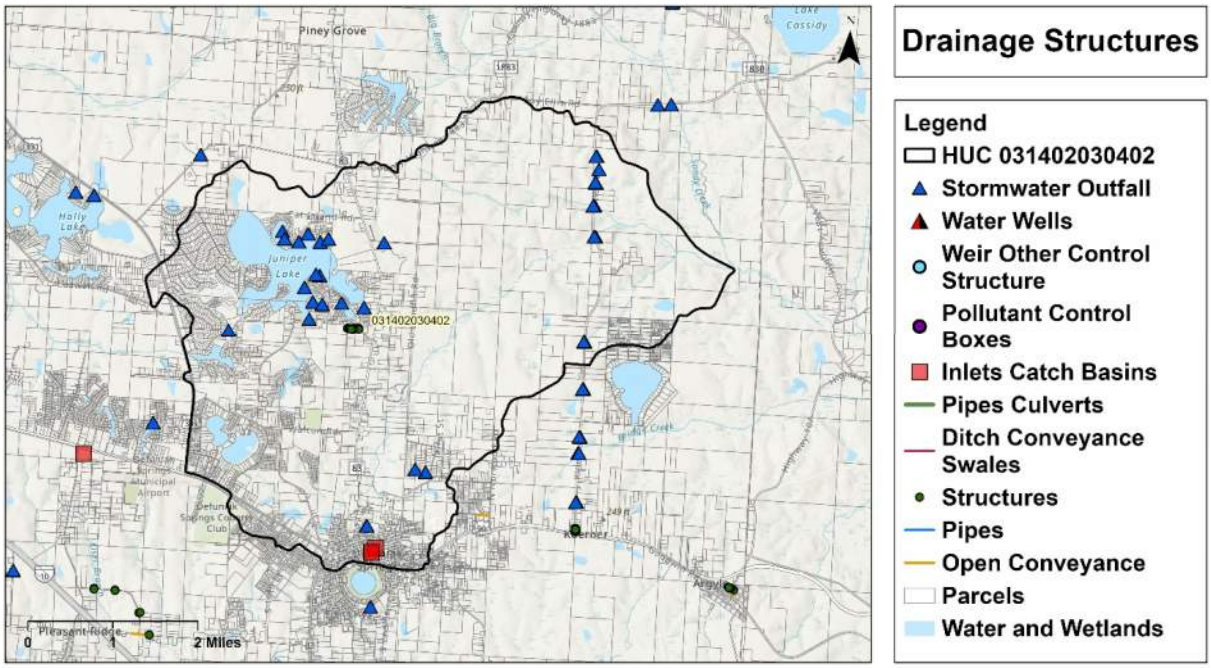

Figure 27. Stormwater Infrastructure for the HUC 031402030402. Processed by FAU.

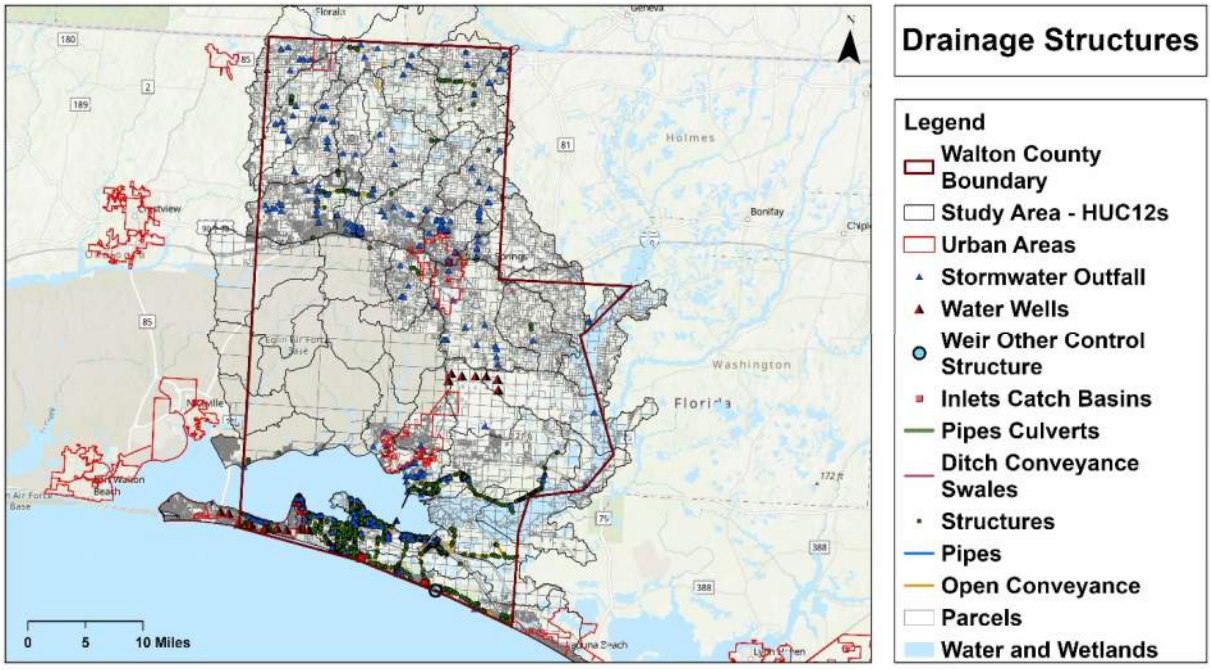

Figure 28.Stormwater Infrastructure for Walton County. Processed by FAU.

Although nature-based infrastructure might be installed, it is not certain. The stormwater system must maintain compliance with the stormwater regulations, which requires record-keeping, policy development, inspections and maintenance. The goals of such stormwater management may include:

- Best landscape practice;
- Control car washing contribution to pollution;
- Enforce the Stormwater Pollution Prevention Plan (SWPPP) by site evaluation, assessment, erosion and sediment controls, preventive maintenance, certification and inspection reporting for construction sites and city planning;
- Implement a hazardous material elimination system;
- Eliminate illicit dumping;
- Proactive and reactive catch basin inspections and maintenance;
- Street sweeping to control debris;
- Maintain swales to help prevent stormwater pollution flooding.

1.13 Data Gaps

FAU has developed comprehensive databases to address the information needed for the vulnerability assessment. These are included in **Error! Reference source not found.**. The data

can be used to model the impacts of flood routing during the storm of interest. As a result, the modeling pieces (discussed in Chapter 2) will include the following:

- Flood response model results (Cascade 2001)
- Flood risk/hazard mapping
- Vulnerability assessments to identify areas of concern for future repetitive losses

There is only one data gap for the area – existing stormwater infrastructure records are incomplete. However, for the purposes of this plan, this data gap does not limit the findings as there are two scales: 1) the sub-watershed level and 2) community hotspots. A neighborhood level vulnerability assessment will require the local infrastructure inventory.

Table 6. List of datasets collected by FAU as of List of datasets collected by FAU for the project (12/20/2020).

2.0 ASSESSMENT OF VULNERABLE AREAS

Defining flood risk due to compounding hydrographic influences is the central concern of this WMP. Modeling and assessment of vulnerability focused on the combination of a high-water table, heavy rains, and impervious conditions that can lead to localized nuisance flooding events. Through a previous survey with local officials, the number of days of continuous nuisance flooding that the public will tolerate before that flooding is considered destructive is about 4 days (E Science 2014).

For a large study area, small parts may actually be at risk. The point is to identify where further study might be needed. A screening tool accomplishes this goal applied to the sub-watershed scale to designate areas that are susceptible to periodic flooding events. Utilizing the information collected and analyzed in Chapters 1 and 2, and comparing to data in Chapter 3, vulnerability can be identified.

2.1 Historical and Existing Challenges

Walton County has faced various historical and existing challenges as well as natural hazards over the years. Some of these include:

- Hurricane and Tropical Storms: being situated along the Gulf Coast, Walton County is vulnerable to hurricanes and tropical storms, which can lead to damage to the built and natural environment, as well as poses risks to human and wild life.
- Coastal Erosion: The county's coastline is subject to erosion due to natural processes and human activities. Erosion can lead to the loss of beaches and threaten coastal structures and properties.
- Flooding: heavy rainfall, storm surges from hurricanes, and other factors can cause localized flooding, particularly in low-lying areas. Flood events can disrupt daily life, damage property, and impact transportation.
- Water Quality and Quantity: as in many coastal areas, managing water quality and maintaining an adequate water supply are ongoing challenges. Pollution from stormwater runoff and other sources can affect water quality, and groundwater resources need to be carefully managed to sustain the growing population.
- Wetland Loss: The county's wetlands face the threat of degradation and loss due to urban development and other human activities. Protecting these essential ecosystems is vital for maintaining biodiversity and mitigating flood risks.
- Urbanization and Development: Balancing the demand for development and growth with the preservation of natural habitats and resources is a persistent challenge. Unplanned

urbanization can lead to habitat destruction, increased runoff, and exacerbate flooding risks.

- Land Use and Zoning: Proper land use planning and zoning are essential to address issues related to population growth, infrastructure development, and natural hazard mitigation. Ensuring responsible development practices can help minimize risks.
- Invasive Species: Like many regions, Walton County faces the threat of invasive plant and animal species. These invasive species can disrupt local ecosystems, negatively impacting native flora and fauna.
- Sea-Level Rise: With rising sea levels due to climate change, coastal communities like Walton County's coastal areas are at greater risk of inundation and storm surges during extreme weather events.

The fast growth of the population and urban development in the coastal areas of the county exacerbates effort to protect open space for land percolation of water. While regulations are in place to reduce the influx of stormwater, the challenges will continue with development.

2.1.1 Existing Management Efforts in the Watershed

The county is under Northwest Florida Management District (NWFMWD) jurisdiction, which covers the Florida Panhandle region. The NWFMWD is responsible for managing and protecting water resources in its designated regions, which includes issues related to water supply, water quality, flood control, and natural resource conservation. Local governments have local stormwater utility infrastructure and planning/policy tools to reduce future flood potential. Most of the major projects to date have been focused on addressing the water quality issues and flooding due to extreme rainfall.

2.1.2 Critical Target Areas Identification

By modeling the HUC 031401030402 sub-watershed flood response to a series of rainfall events and sea levels (plus king tides), and further classifying flood risk as the probability of inundation, it is possible to identify critical target areas. These areas are particularly vulnerable to flooding and are subject to further study through a scaled-down modeling approach. The screening tool is first applied at the greater watershed level to provide an initial risk assessment focused on the hydrologic response to a rainfall event given the unique characteristics and features of the sub-watershed or study area. The process is discussed later in Section 2.2 with results presented in Section 2.4.

2.1.3 Potential Preservation Areas

Walton County boasts several areas with high biodiversity value. These areas include the unique coastal dune lakes, which support diverse ecosystems and contribute to water quality along the coast. Wetlands are crucial habitats that provide refuge for a variety of plant and animal species while acting as natural water filters. State parks like Topsail Hill Preserve and Grayton Beach State Park are valuable conservation areas with diverse coastal ecosystems. Additionally, preserving the Choctawhatchee River Basin is essential for the biodiversity of the region.

2.2 Vulnerability Maps

2.2.1 Screening Tool

The screening tool utilizes topographic data from various sources (Section 1.1), water table elevations (Section 1.2) and surface water gauges (Section 1.3) downloaded from the NWFWMD website, tidal information for coastal areas obtained from the NOAA Current & Tides website (Section 1.3), soil maps obtained from the USDA (Section 1.4), and another key dataset as described previously in Chapter 1. The design storms are discussed in Section 1.6. The reason this is critical is that to do any modeling (as required by the CRS program), a screening tool should be used to identify regions with a high risk of inundation based on multiple collected datasets and hydrological models. Figure 29 shows how the GIS layers interface in the tool and how they are combined for spatial analysis.

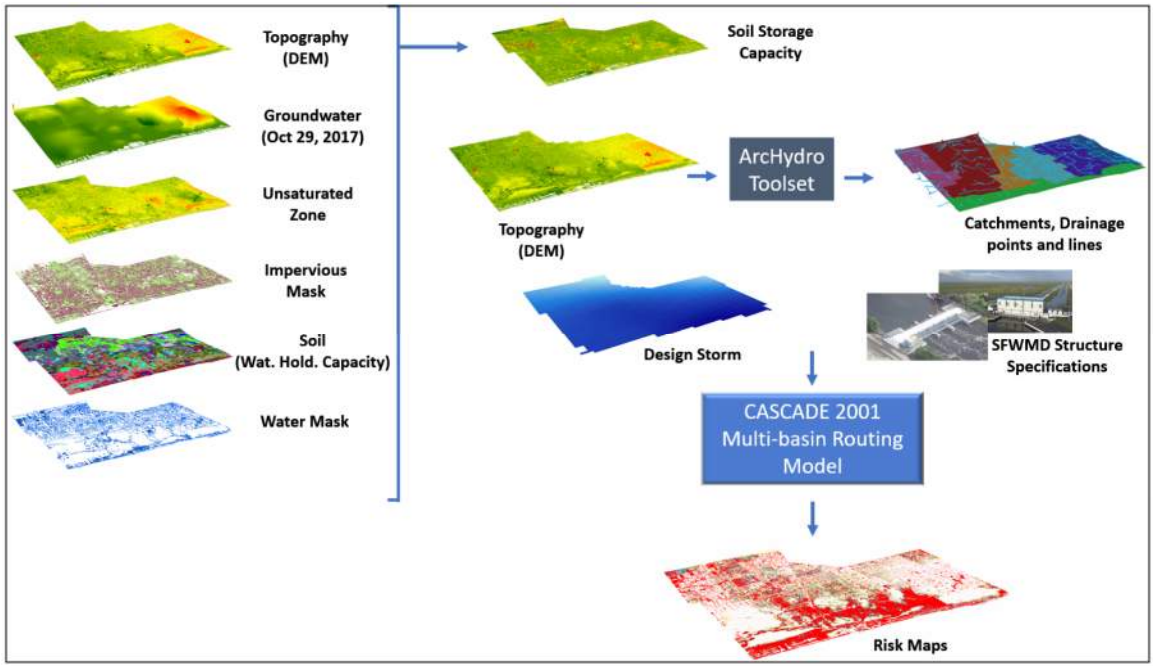

Figure 29. Screening tool methodology for creating flood risk maps.

The model chosen for this screening tool is Cascade 2001, which is a multi-basin hydrologic/hydraulic routing model developed by the SFWMD. The model permits the investigator to run different storm events to determine flooding scenarios. The boundaries are critical for basin studies and must be chosen carefully. The following data layers collected in the prior section are processed to develop the input files for Cascade 2001:

- Topography
- Soils
- Development intensity
- Groundwater elevations
- Surface water/Outlet locations

The software creates a glass box where water rises to a certain level and then decreases. Running the simulation requires defining the basin (HUC or sub-HUC) and input of the following data:

- Area
- Portion of area above a given elevation
- Initial groundwater stage
- Longest travel time for the runoff to reach the most distance point of discharge
- Ground storage as estimated from the USDA gridded National Soil Survey Geographic Database (gNATSGO)

Ground storage ≈ (Water holding capacity) × (Surface elevation – GW elevation)

= 2 × (AWS for a soil layer of 0-150 cm) / 150cm × (Surface elevation – GW elevation)

- Available water storage (AWS) for a soil layer of 0-150 cm
- Average amount of precipitation that can be stored in the soil layer

The output from the model is an elevation surface that can be used to develop a flood map for the study area (**Error! Reference source not found.**), which shows the spatial distribution of probabilities of flooding during the modeled 1-day 100-year storm event.

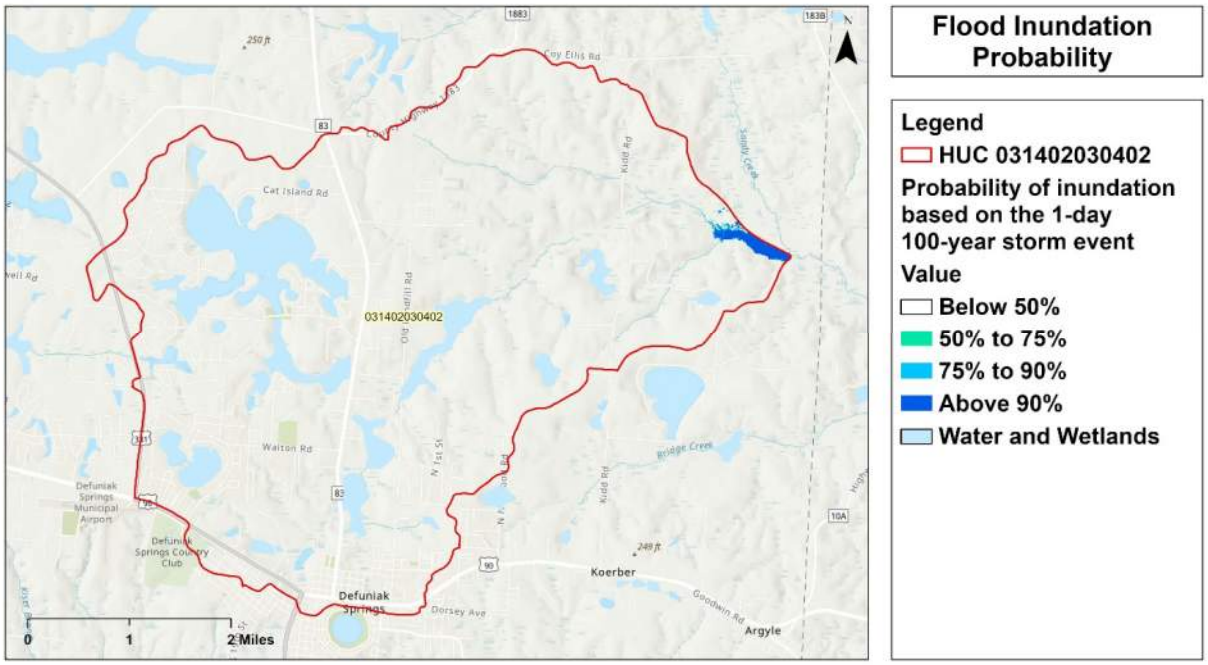

Figure 30. Probability of flood risk map during the modeled 1-day 100-year storm event for the HUC 031402030402, processed by FAU.

2.2.2 Identification of Vulnerable Areas

Given these assumptions and the Cascade 2001 outputs, the goal of this methodology is to produce a spatially-temporally quantified understanding of nuisance-destructive flood potential in the study area given observed values. Risk is a function of compounding geo-hydrological features, namely, surface water, groundwater, topography, build-out, and time of year. A GIS-based algorithm and spatial interpolation generated layers of the greatest observable hydrographic surfaces. These outputs were then compared with high resolution topographic LiDAR data to develop digital elevation models that reflect the observed risk landscape. These models can then be combined into Cascade 2001 to produce vector and volume information, in combination with soils, vegetation and impervious surfaces, allowing the observed model outputs to be extrapolated into a more predictive context.

To evaluate flood vulnerability at this scale, the analysis starts with a binary flooding surface (0 = below 50% chance of flooding; 1 = above 50% flooding) based on output from the screening tool for a specified design storm. Next, attributes of that raster based on "VALUE = 1" query are extracted using *Extract by Attributes* tool. Then the *Batch Project* tool was used to map critical facilities data to the common coordinate system (NAD83 UTM Zone 17N), unit = meters. Then a field was added using *Add Field* for [PriorityTier] = assigned Tier #1-4 value from the DOR codes and [Area_sqmeter]. The critical facilities layers were then merged into a single layer to calculate the polygon geometry for [Area_sqmeter] using the *Merge* tool. Next, *Zonal Statistics as Table* is used to calculate the SUM of flooded values ("VALUE = 1") within each critical parcel. Output table has fields for SUM (i.e., total # of flooded pixels per critical parcel) and AREA in map units of square meters (since each pixel in the flooding surface has a cell size of 3-meters by 3-meters, each area is equal to the SUM value multiplied by 9 m^2). Using the *Join Field* tool, the SUM and AREA fields are joined to the merged critical facilities layer based on a key attribute, first renaming these fields for clarity (e.g., AREA_FLOODED_3d25y). Once all field data is included, the next step involves using *Export Table* to export the dataset as a CSV file. Note that non-flooded parcels have zero flooded area, so they receive a <Null> value from the zonal statistics tool. To replace null values with zeros, we use *Calculate Field* in the attribute table along with the following Python expression (replacing the respective field name): "0 if !AREA_FLOODED_3d25y! is None else !AREA_FLOODED_3d25y!". Next, the CSV file is saved as an Excel Workbook (.xlsx). The Range is converted to an Excel Table, and the columns are rearranged in the desired order. Finally, the "percent-flooded" columns are calculated as follows:

- PCT_FLOODED_3d25y = ([@[AREA_FLOODED_3d25y]]/[@[TotalArea_sqmeter]])*100
- PCT_FLOODED_1d100y = ([@[AREA_FLOODED_1d100y]]/[@[TotalArea_sqmeter]])*100

After this calculation, the table is sorted to show the higher priority tiers and higher percent-flooded values first. To reduce the number of critical facilities shown in the final table, a filter was created to show only critical facilities with 10% or more flooded area in the parcel during both storm events. Records with duplicate parcel ID numbers were removed from the table. The results of this procedure are discussed in Section 5.2 of this document.

With respect to dams and levees, for purposes of the NFIP, FEMA only recognizes systems that meet, and continue to meet, minimum design, operation, and maintenance standards that are consistent with comprehensive floodplain management criteria. The Code of Federal Regulations, Title 44, Section 65.10 (44 CFR 65.10) describes the information needed for FEMA to determine if a levee system reduces the risk from the 1% annual chance flood. FEMA has accredited levees and Provisionally Accredited Levees (that have a specified timeframe to obtain the necessary data

to confirm the levee's certification status). If a levee system no longer meets Section 65.10, FEMA will de-accredit the levee system and issue an effective FIRM showing the levee-impacted area as a SFHA. FEMA coordinates its programs with USACE, who may inspect, maintain, and repair levee systems. USACE has authority under Public Law 84-99 to supplement local efforts to repair flood control projects that are damaged by floods. Like FEMA, USACE provides a program to allow public sponsors or operators to address levee system maintenance deficiencies. Failure to do so within the required timeframe results in the levee system being placed in an inactive status in the USACE Rehabilitation and Inspection Program. Levee systems in an inactive status are not eligible for rehabilitation assistance under Public Law 84-99. There are no levees/dams listed in the sub-watershed study area.

2.3 Modeling Results

Error! Reference source not found. to **Error! Reference source not found.** are a series of maps that depict risk of flooding in the basin based on the following scenarios:

1. 3-day 25-year storm event. Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (**Error! Reference source not found.**)
2. 1-day 100-year storm event. Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (**Error! Reference source not found.**)
3. 1-day 10-year storm event. Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (**Error! Reference source not found.**)
4. 1-day 5-year storm event. Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (**Error! Reference source not found.**)

In all storm event scenarios, a small portion of flooding is noted at the creek entrance to the HUC. As this basin is not connected to the ocean and its altitude is above 20 feet, the HUC is expected to remain unaffected by sea level rise, therefore SLR scenarios were not computed.

The design storm simulation determined that approximately 0.44% of the HUC total area or 0.097 mi² has a probability of inundation above 50% for a 3-day 25-year design storm. For comparison, approximately 0.45% of the HUC's total area, or 0.1 mi² would be expected to be inundated during a 1-day 100-year design storm. Approximately 0.38% of the HUC's total area, or 0.083 mi², would be expected to be inundated during a 1-day 10-year design storm. Finally, approximately 0.37% of the HUC's total area, or 0.082 mi², would be expected to be inundated during the 1-day 5-year storm. **Error! Reference source not found.** compares the four storm events..

Table 7. HUC 031401030402 expected inundated area by storm event.

Storm Event	Area with probability of	Area with probability of	Area with probability of	Area with probability of

	inundation below 50% (Sq Mi)	inundation above 50% (Sq Mi)	inundation below 50% (%)	inundation above 50% (%)
3-day 25-year	21.872	0.097	99.56%	0.44%
1-day 100-year	21.869	0.100	99.55%	0.45%
1-day 10-year	21.886	0.083	99.62%	0.38%
1-day 5-year	21.887	0.082	99.63%	0.37%

2.4 Risk and Vulnerability

The screening tool modeling exercise from the prior section identified areas within the communities that are vulnerable to flooding. Higher priority concerns should be those properties or assets that are considered
essential and need to be kept in service during a flooding event. All other improvements are local. To help with prioritization, the following is suggested:

- Tier 1 - Critical facility protection (water/sewer utilities, public safety, hospitals, schools, power, shelters)
- Tier 2 - Essential facilities (groceries, pharmacies, roadways)
- Tier 3 - Economic centers (protecting jobs)
- Tier 4 - At risk communities
- Tier 5 - Other urban/suburban property
- Tier 6 - Agriculture/public property/vacant/undeveloped

Error! Reference source not found. outlines the priority of land use based on DOR land use codes from the property appraiser's office and assigns an associated priority level to each parcel. Note that for residential property, identifying at-risk communities (income, age, disability, health) requires a further drilldown to the neighborhood level (i.e. wealthy neighborhoods with few older,

poor health individuals would have a lower priority than at risk communities, which generally have lower value housing and denser development). In the latter case, more people are impacted, and those people have less ability to mitigate risk. Based on these priorities, the relative risk priority DOR land use codes were evaluated based on a scale of 1 to 6, where 1 is higher priority (more vulnerable) and 6 is the least priority (least vulnerable).

97	Outdoor Recreational Or Parkland, Or High-Water Recharge Subject To Classified Use Assessment	6
98	Centrally Assessed	6
99	Other Non-Agricultural Acreage	6
100	Parcel With no Values	6
101	Parcels With no Values (ROW - avenues, highways, arterials)	2
102	Parcels With no Values (Water)	6
103	Parcels With no Values (Rail)	2

Having assigned the risk priority from 1 to 6 in the DOR codes and the percentage of the parcel that floods during the applicable design storm, properties that are more critical to the function of the community can be identified. The methodology is to first convert the DOR code priority tier to its inverse scale by the following equation:

Consequence of risk factor = 7 – DOR Code Priority Tier

The flood risk factor from the screening tool is interpreted based on flooding probability. We take all parcels in tiers #1-4 that have a greater than 50% chance of flooding during a particular design storm and calculate the percent of the parcel that would flood during that event. The percentage is converted to a 6-point scale termed as the Flood Risk Factor, shown in **Error! Reference source not found.**.

Table 9. Flood Risk Factor Classification.

Percent of Parcel Flooded	Flood Risk Factor
90-100%	6
80-89%	5
70-79%	4
60-69%	3
50-59%	2
<50%	1

The priority is further developed by assigning 75% of the importance to the consequence of flooding and 25% importance to flood risk, or three times the importance to the consequence of flooding to come up with a composite score as follows:

Flood Risk Factor × 25% + Consequence of Risk Factor × 75% = Composite Score

Example: 1 × 25% + 6 × 75% = 4.75

Those higher priority properties that received the higher composite score are where the mitigation strategies and financial resources should focus first.

2.4.1 Results

Error! Reference source not found. and **Error! Reference source not found.** depict the HUC 031402030402 sub-watershed priority of land uses showing the critical facilities that should receive priority. The first map (**Error! Reference source not found.**) exclusively displays critical facility parcels within the HUC without any flooding. The second map (**Error! Reference source not found.**) overlays critical facilities onto the 1-day 100-year storm event scenario. **Error! Reference source not found.**is a mosaic showing critical facilities overlaid in the 1-day 100-year storm event for the whole county.

Additionally, **Error! Reference source not found.**illustrates the composite score based on 1-day 100-year storm event for the HUC, which is the result of the calculations explained above, pinpointing parcels that should be prioritized. It considers only parcels classified as 1 to 4 tiers, and within the 50% probability of inundation area. Lastly, **Error! Reference source not found.**

is a mosaic showing the results for composite score overlaid in the 1-day 100-year storm event for the coastal area of Walton County. As the subwatershed is not coastal, the results based on 5 ft. SLR + 1-day 100-year storm event were not computed for the basin.

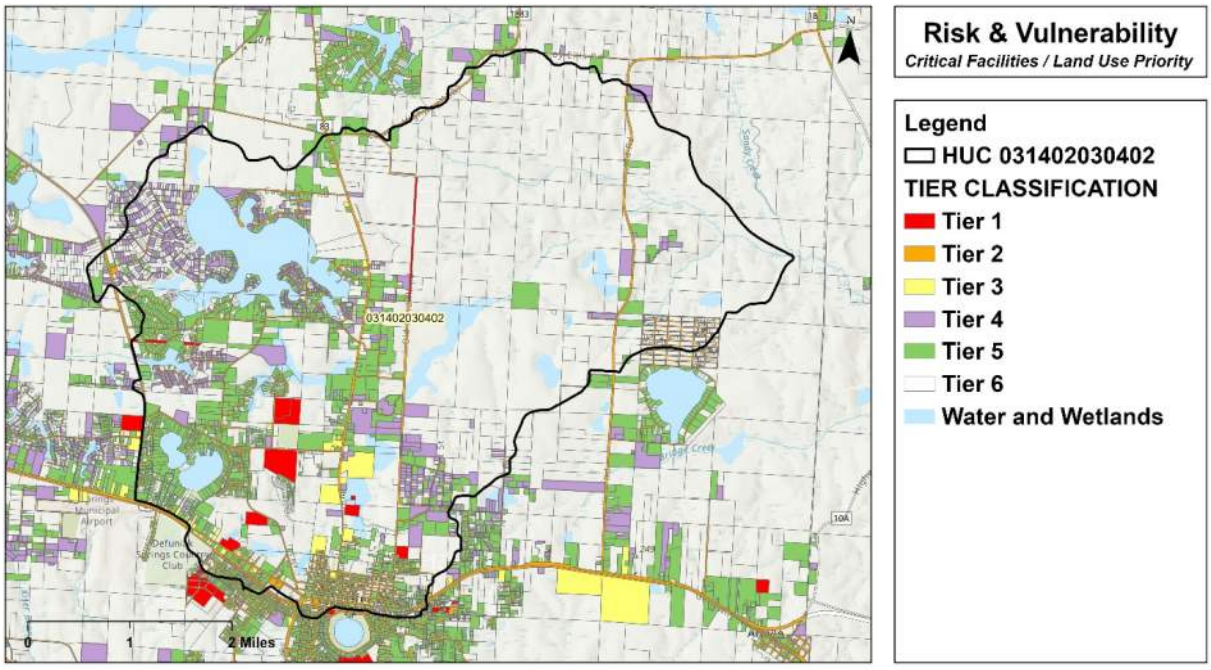

Figure 35. HUC 031402030402 sub-watershed Critical Facilities (priority of land uses) map. Processed by FAU.

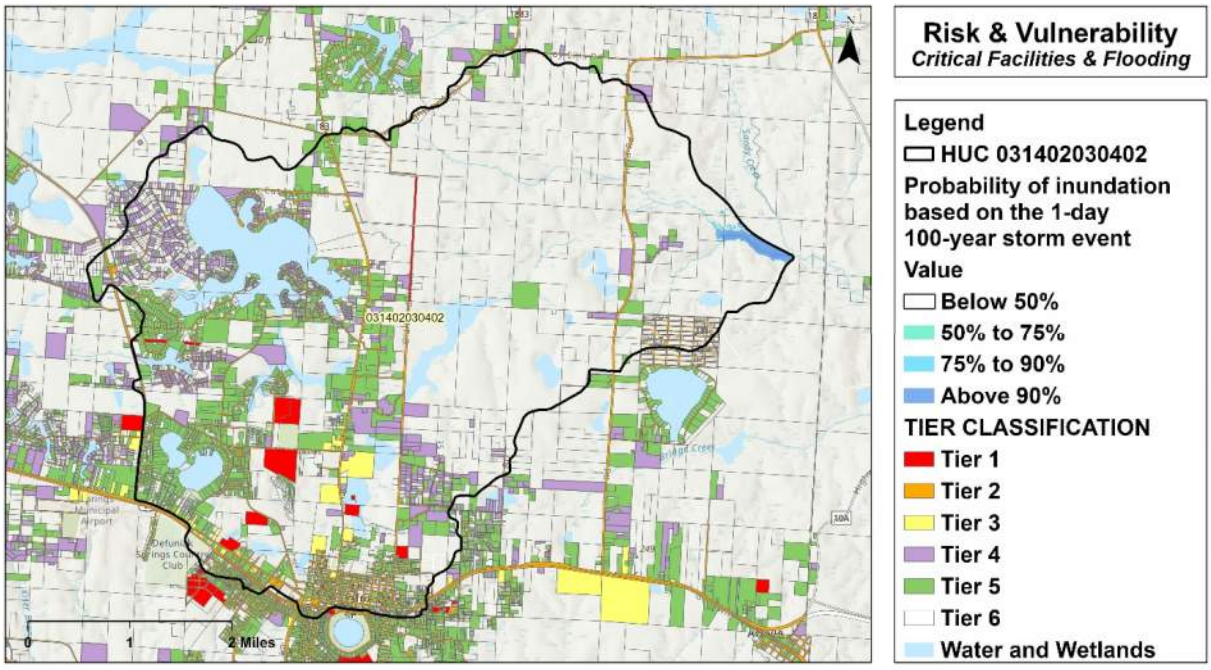

Figure 36. HUC 031402030402 sub-watershed Critical Facilities (priority of land uses) map overlaid on the 1-day 100-year storm event probability of inundation. Processed by FAU.

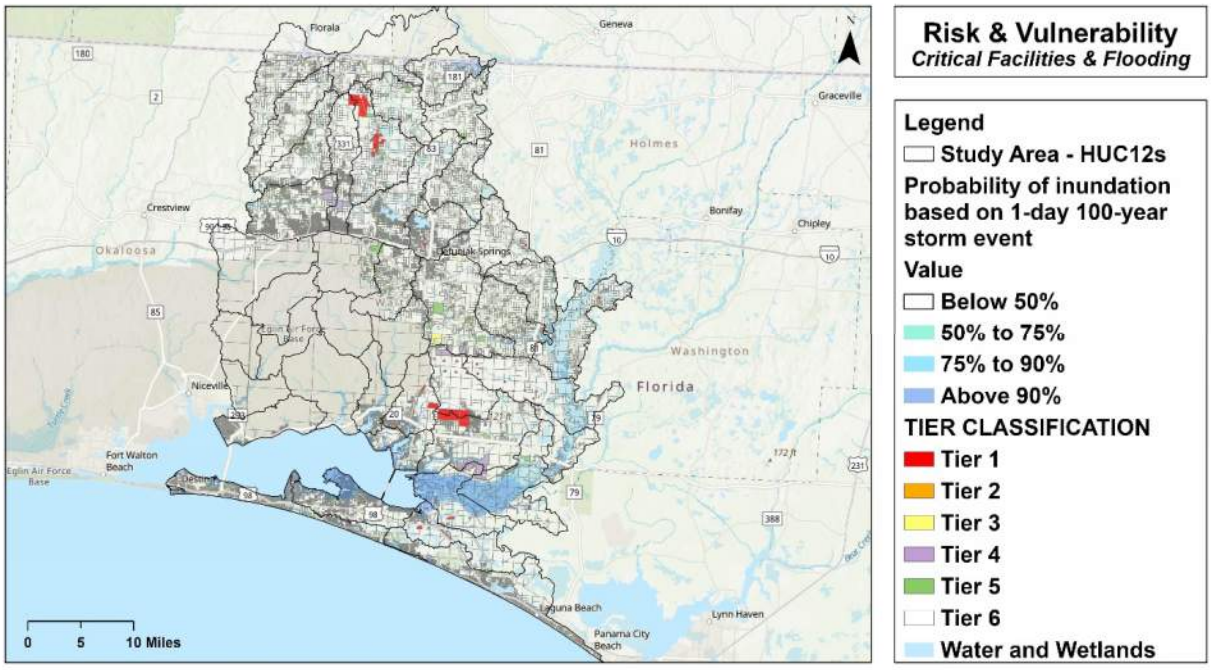

Figure 37. Walton County (mosaic) - Critical Facilities (priority of land uses) map overlaid on the 1-day 100-year storm event probability of inundation for Walton County. Processed by FAU.

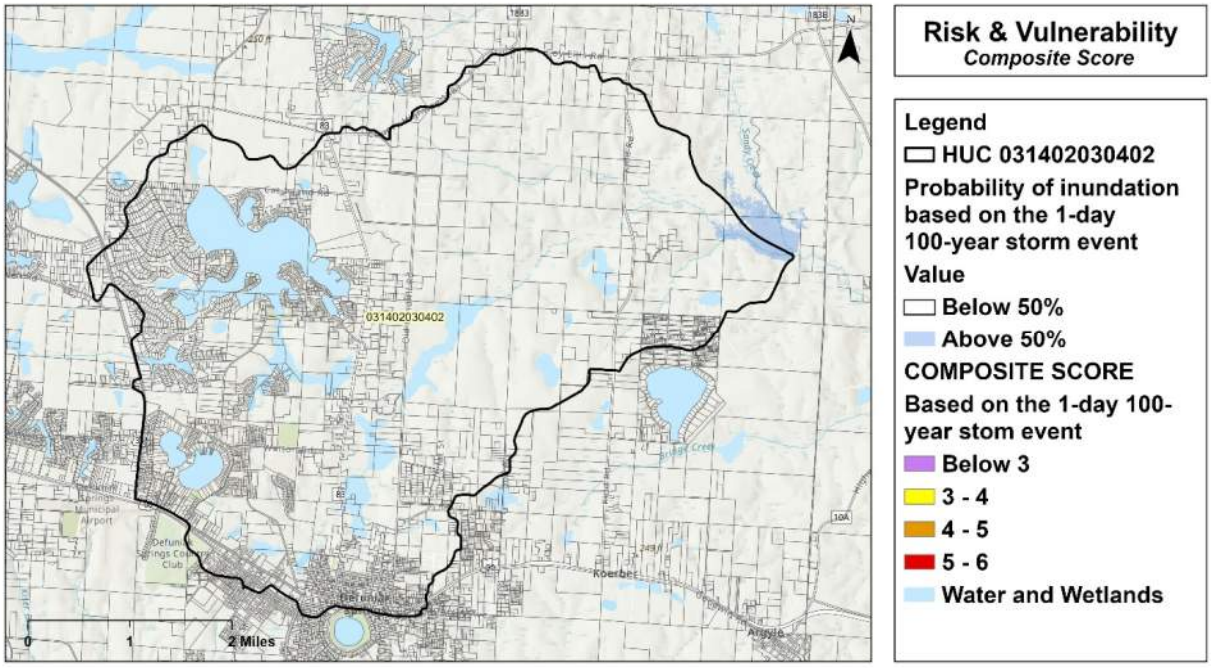

Figure 38. HUC 031402030402 sub-watershed Composite Score Risk map, with calculation based on 1-day 100-year storm event. Processed by FAU.

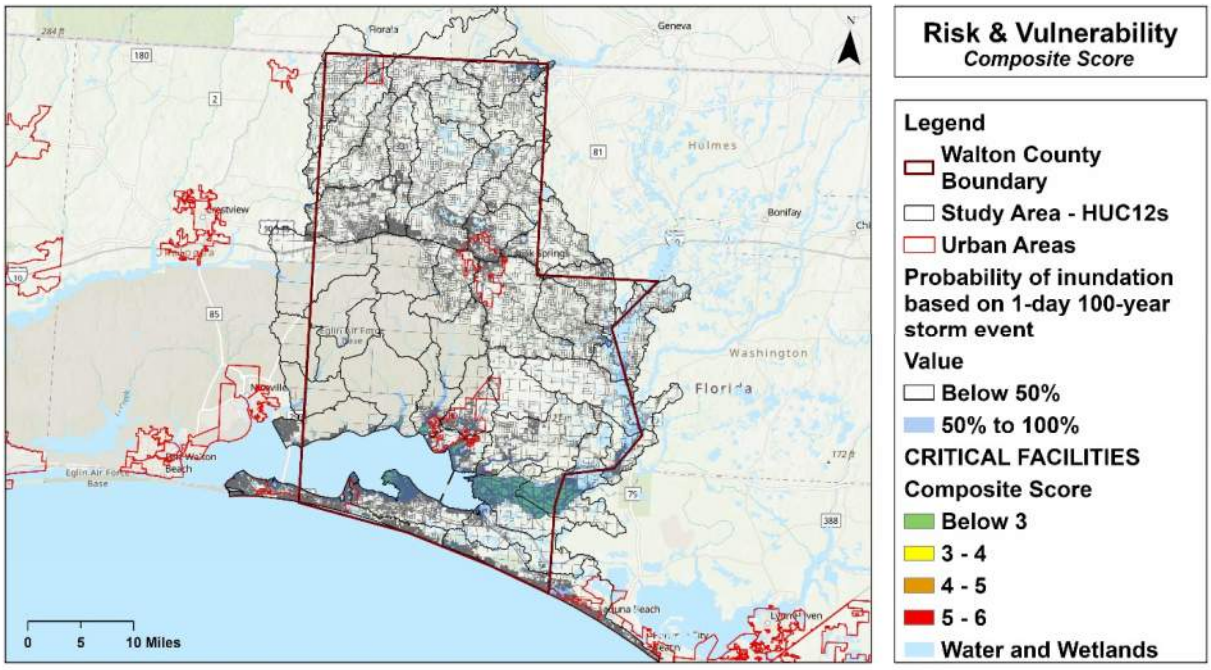

Figure 39. Walton County (mosaic) - Composite Score Risk map overlaid on the 1-day 100-year storm event probability of inundation. Processed by FAU.
Please note that due to the scale of the map, the composite score layer is not properly visible in this map.

Please note that the composite score results display outcomes exclusively for parcels within the flooding path area. Consequently, for parcels outside this flooding path, the composite results will be null. The composite score combines the flooding path area with the land use priority results to identify the most vulnerable areas deserving of priority.

2.4.2 Drill-down – DeFuniak Springs

For enhanced visualization of the urban areas within this HUC 031402030402, Figure 40 to Figure 44 illustrate the same results for critical facilities (land use priorities) and composite scores, but on a reduced scale, which better facilitates the examination of finer details within the urban area (DeFuniak Springs). These maps cover both the 1-day 100-year scenario and the 1-day 100-year + 5 feet SLR scenario, although the results for Sea Level Rise is null due to distance of the basin to the coast and its high elevation.

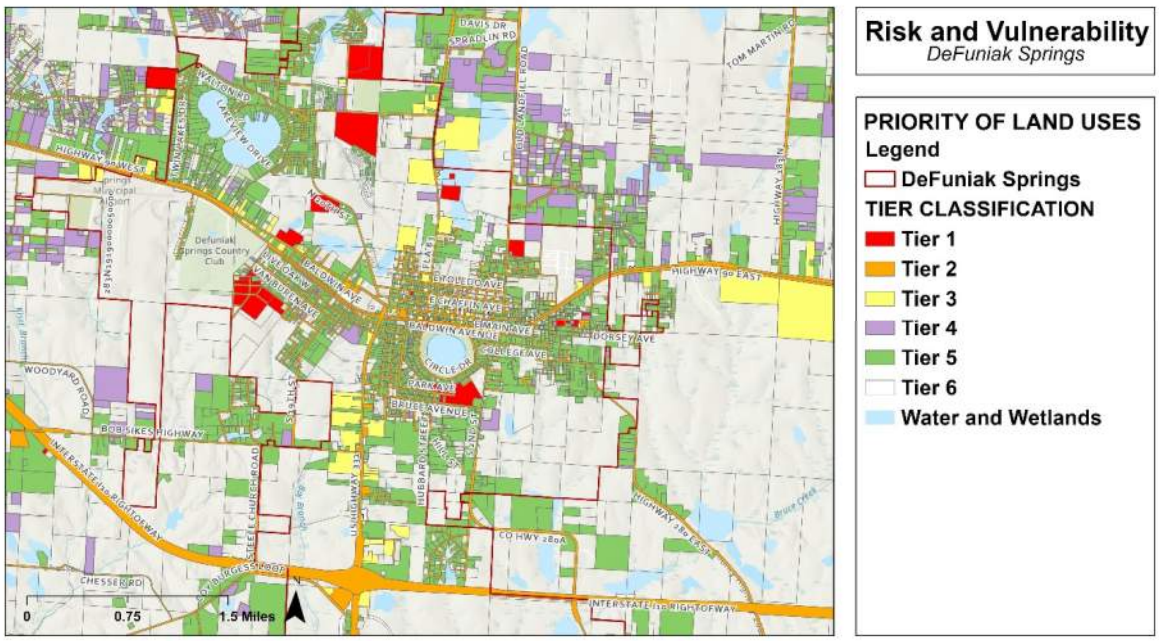

Figure 40. Critical Facilities (priority of land uses) map for DeFuniak Springs. Processed by FAU.

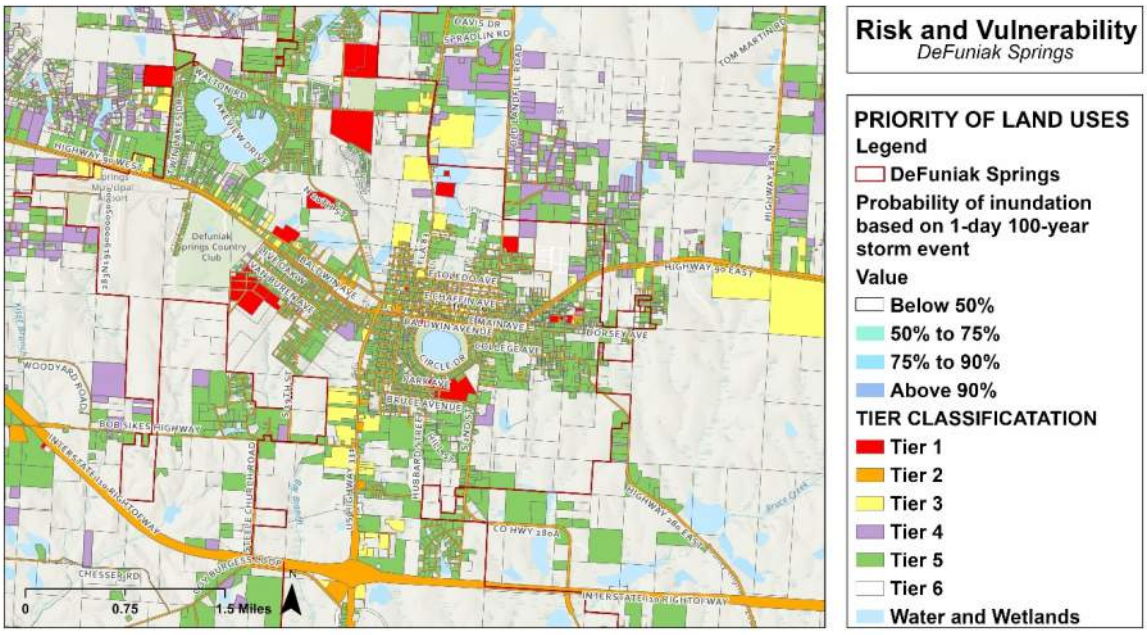

Figure 41. Critical Facilities (priority of land uses) map overlaid in the 1-day 100-year storm event for DeFuniak Springs. Processed by FAU.

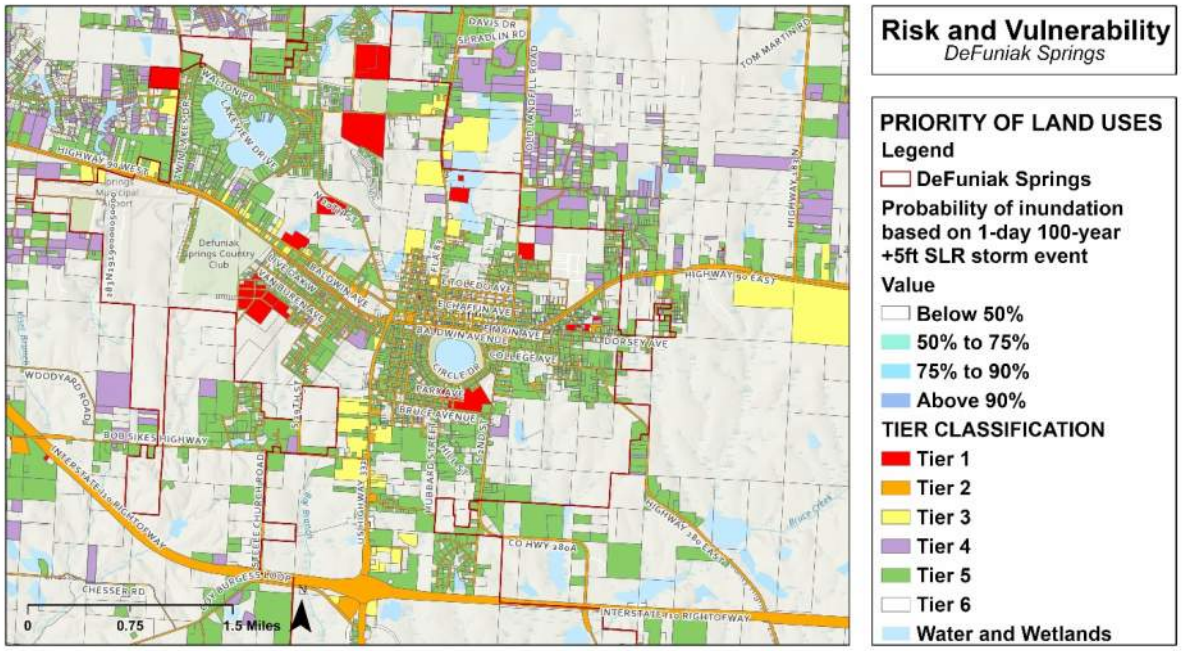

Figure 42. Critical Facilities (priority of land uses) map overlaid in the 1-day 100-year storm event + 5ft SLR for DeFuniak Springs. Processed by FAU.

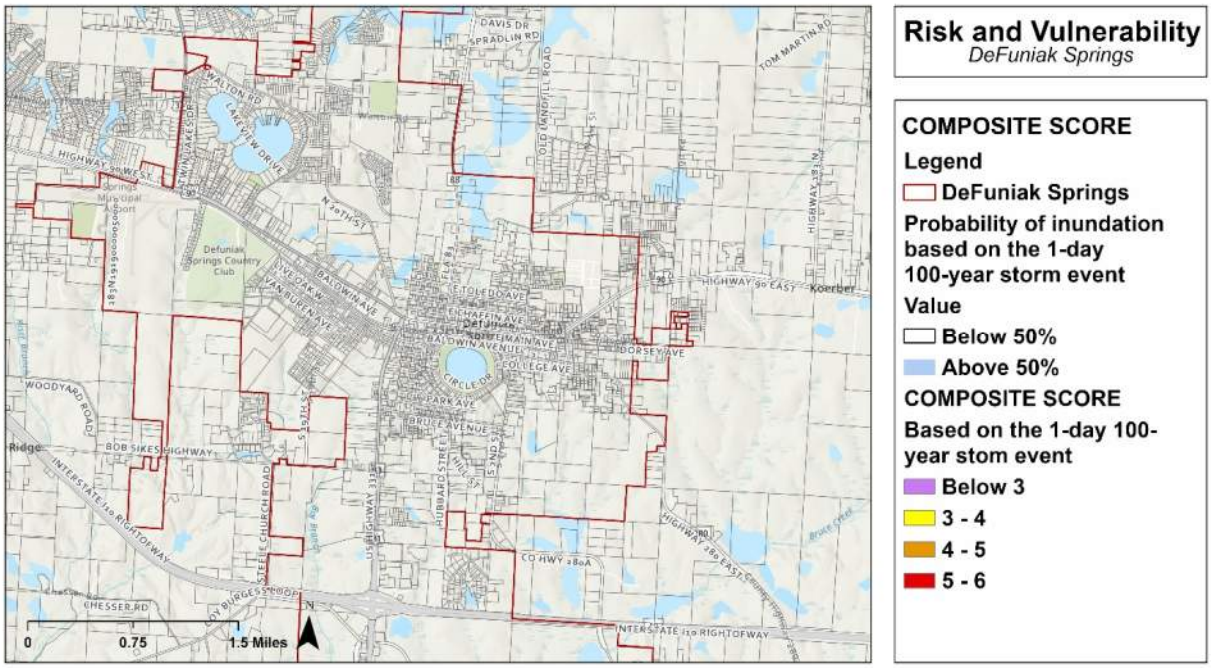

Figure 43. Composite Score map based on 1-day 100-year storm event, overlaid in flooding layer for DeFuniak Springs. Processed by FAU.

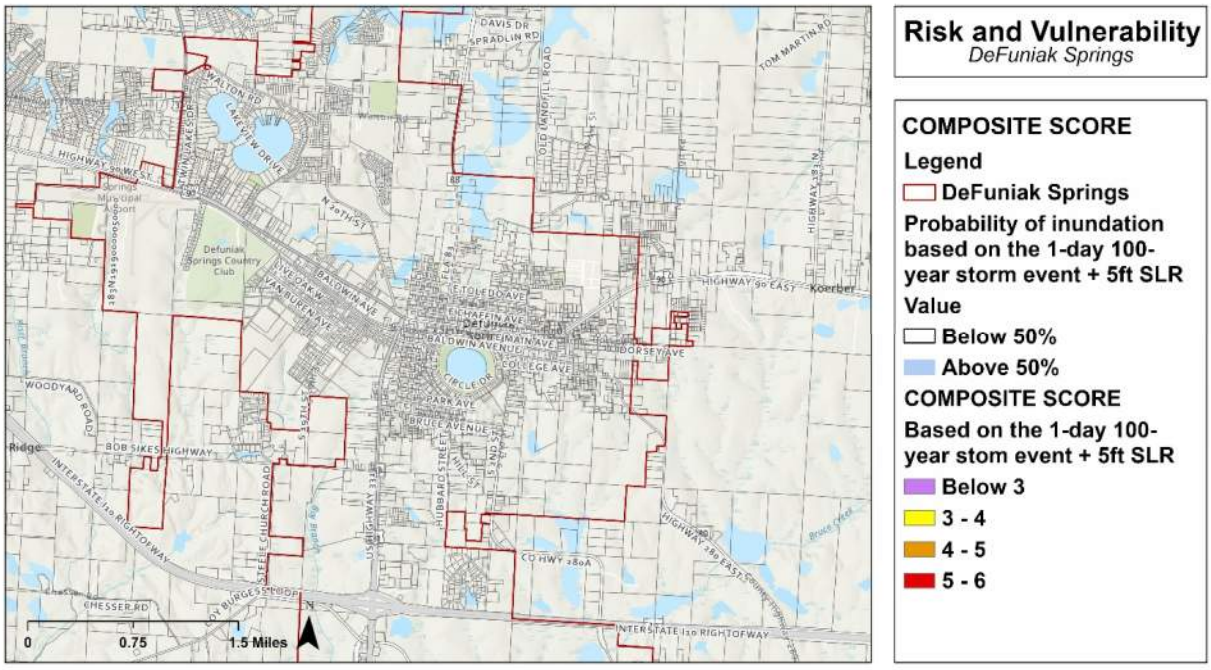

Figure 44. Composite Score map based on 1-day 100-year storm event + 5 feet SLR, overlaid in flooding layer for DeFuniak Springs. Processed by FAU.

The composite score results for this location are null, as the city of DeFuniak Springs shows no indication of flooding in both the 1-day 100-year and 1-day 100-year + 5ft SLR flooding scenarios.

2.4.3 Solutions

Chapter 5 of the Watershed Master Plan for Walton County describes a list of possible gray and green stormwater strategies to combat flooding that can be implemented as solutions for the county. The same solutions can also be applied at the HUC level, including HUC 031402030402. A summary of these flood mitigation strategies is listed in **Error! Reference source not found.**.. For more detailed information, please see Chapter 5-5.3 (Solutions).

Table 10. List of possible gray and green stormwater strategies to combat flooding.

Strategy Class	Implementation Strategy	Applications	Benefits	Cost	Barriers to Implementation
Green	Rainwater harvesting	Local, small scale, easily implemented in developed areas	Protects property, treats runoff	Under $5,000	Limited volume disposed of, so many are needed, maintenance
Gray	Pervious paving	Parking lots, patios, driveways, anything except paved roads due to traffic loading	Reduces roadway and parking lot flooding	$10-20/sf, requires bumpers and sub-base to maintain paver integrity	Must be maintained via vacuuming or the perviousness fades after 2-3 years
Green	Detention	Common for new development, but difficult to retrofit; limited to open areas	Removes water from streets, reduces flooding	$200K/ac	Land availability, maintenance of pond, discharge location Uses up land that could otherwise be developed
Gray	Exfiltration Trench	Any low-lying area where stormwater collects and the water table is more than 3 ft below the surface; densely developed areas where retention is not available, roadways	Excess water drains to aquifer, some treatment provided	$250/ft	Significant damage to roadways for installation, maintenance needed, clogging issues reduce benefits
Gray	Central sewer installation	All areas where there are septic tanks. Mostly a water quality issue	Public health benefit of reducing discharges to lawns, canals, and groundwater from septic tanks	$15,000 per household	Cost, assessments against property owners, property rights issues
Green	Flood prone property acquisition	Regional agency - could be any low-lying areas	Removes flood prone areas from risk	$2K-$100K/ac depending on whether it is already developed	Difficult to implement if occupied, issues with willing sellers, cost, lack of funds for acquisition
Gray	Pump stations	Any low-lying area where stormwater collects, and there is a place to pump the excess stormwater to such as a canal; common for developed areas	Removes water from streets, reduces flooding	Start at $1.5 to 5 million each, number unclear without more study	NPDES permits, maintenance cost, land acquisition, discharge quality
Gray	Armored sewer systems	Any area where gravity sanitary sewers are installed	Keeps stormwater out of sanitary sewer system and reduces potential for disease spread from sewage overflows	$500/manhole	Limited expense beyond capital cost

Strategy Class	Implementation Strategy	Applications	Benefits	Cost	Barriers to Implementation
Gray	Sea walls	Barrier islands and downtown coastal areas	Protects property	$1200/ft	Private property rights, neighbors
Policy	Changes in land use	Applicable universally	Achieves flood risk mitigation by adjusting permitted land use	Low but may incur private property rights conflicts and litigation	Private property rights conflicts and litigation
Gray	Roadway base protection	Low-lying areas, coastal communities	Protects roads and access routes	$1 million per lane-mile	Cost, adjacent properties become uninsurable
Policy	Enhanced elevation of buildings	Developers would implement this for new construction	Reduced flood risk	Varies	Potential issues with building structure or latticework, and existing homes that are not elevated

2.4.4 Impacted Adjustment Areas

In the evaluation of flood risk management strategies within the framework of the National Flood Insurance Program Community Rating System (CRS), the concept of impact adjustment plays a pivotal role in determining the extent to which CRS-credited activities or elements influence the vulnerability of a community's Special Flood Hazard Area (SFHA) and the structures located within it. It's important to note that while the usual results of impact adjustment are related to the SFHA area, in this specific analysis, it was used 1-day 100-year storm event inundation area performed by FAU instead.

In this context, the following table presents a breakdown of the impact adjustment calculations for a 1-day 100-year storm event inundation. The values are expressed in acres and depict the areas of interest as well as the deductions considered in the evaluation process.

The outcomes of these calculations provide valuable insights into the impact adjustment scenarios:

With ALL State Lands:

This scenario reflects the remaining inundation area after accounting for deductions A, B, and C. It represents the effect of CRS-credited activities without considering the influence of state lands in managing flood risks.

With NO State Lands:

In this case, the remaining inundation area is determined by considering all deductions, including state lands (both open space and not open space– see **Error! Reference source not found.**).

These calculations highlight the dynamic nature of impact adjustment within the CRS framework. By accurately gauging the influence of individual elements, the system ensures that credit allocations align closely with a community's efforts in flood risk mitigation.

Table 11. Impacted Adjustment Areas for HUC 031402030402. Processed by FAU.

AREAS	**ACRES**
HUC-12 Sub-watershed: 031402030402	14060.25
All of the 1-day 100-year storm event inundation	**63.86**
Subtract	
A. Bodies of Water in 1-day 100-year inundation > 10 acres	0.00
B. Federal Land in 1-day 100-year inundation > 10 acres	0.00
C. Reservation/Tribal Land in 1-day 100-year inundation > 10 acres	0
D. State Land in 1-day 100-year inundation > 10 acres that is open space	0.00
E. State Land in 1-day 100-year inundation > 10 acres that is NOT open space	0.00
The remainder is either:	
With ALL State Lands: All of the 1-day 100-year inundation minus (A+B+C) or	63.86
With NO State Lands: All of the 1-day 100-year inundation minus (A+B+C+D+E)	63.86

2.4.5 Repetitive Loss Property Map

A Repetitive Loss (RL) property is a building that has had two or more loss or damage due to a specific hazard, such as floods, hurricanes, or other natural disasters, over $1,000 each, paid by the National Flood Insurance Program (NFIP) within any ten-year period since 1978. There are more than 122,000 RL properties in the nationwide (FEMA, 2005).

These data are essential for assessing the vulnerability of certain areas to recurrent losses and for developing strategies to mitigate the risks. However, due to privacy concerns, the data cannot be openly shared with the public. For this reason, the data were converted into a hot spot analysis map. These maps, instead of identifying the specific location of the repetitive loss properties, highlight clusters of repetitive loss claims and areas where the probability of repetitive losses is higher than would be expected by random chance. In other words, it helps pinpoint locations that have a higher concentration of properties prone to repetitive losses. Figure 45 indicates the results from hot spot analysis in point data, showing aggregated counts, and raster data, showing the estimated probability of repetitive loss.

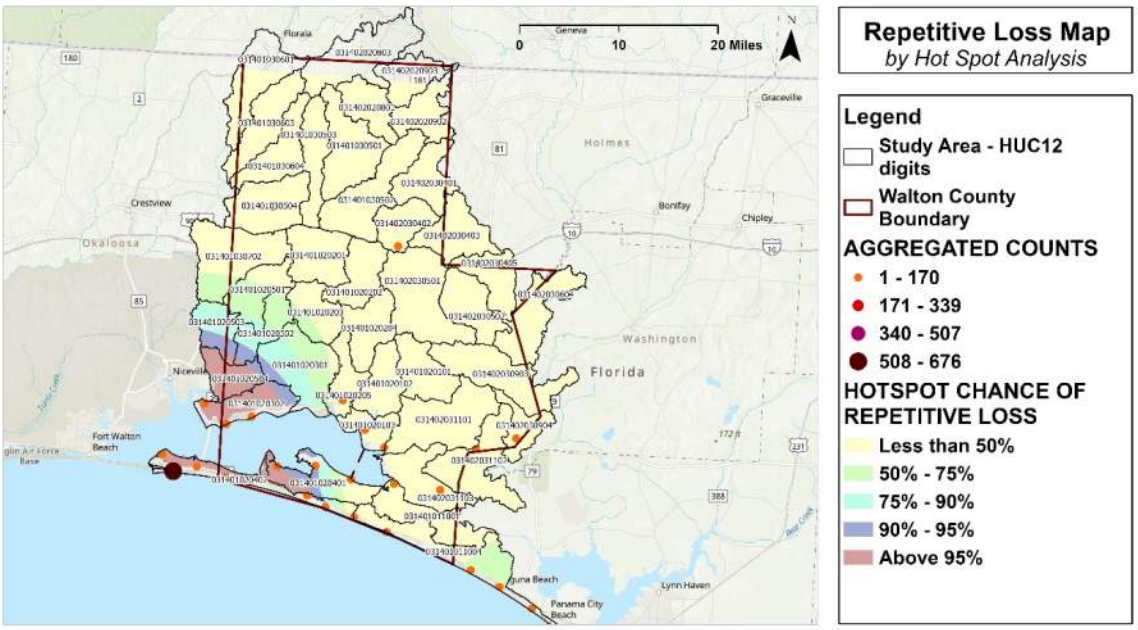

Figure 45. Repetitive Loss map for Walton County by Hot Spot Analysis. Processed by FAU.

2.4.6 Priority Projects

Although the basin features a significant amount of developed land, including a portion of the city of DeFuniak Springs, none of the priority parcels fall within the flood zone. Flooding in the area is minor and not alarming. Consequently, when considering the composite score, it is notable that the results are null, indicating no priority for intervention within the basin.

X.0 EXECUTIVE SUMMARY

The goal of the appendices to the watershed plan are to outline the issues associated with the individual HUC12s that contribute or impact the community's flood vulnerability and there for its flood protection efforts. Floodplain analysis includes developing a watershed model and identifying associated inundation polygons. It builds upon information generated from the watershed evaluation so that planning and management decisions can be formulated.

This appendix describes the issues and modeling associated with one of the HUC12s that affects Walton County. In developing the County-wide plan, this HUC 12 was analyzed so as to determine how it brings or removes floodwaters from the County. For the NFIP process the goal is to analyze all communities at the HUC12 level. From a community perspective the HUC12 is less useful to residents than a community-wide plan. Hence in all cases the HUC12 results were mosaicked into the community-wide plan. Details can be found in the HUC12 appendices, some of which were brought into the community plan.

To reduce redundancy, information of the plans, ordinances, policies and regulations were rolled up to the community-wide plan and will not be repeated in the appendices. Likewise, the community wide mapping was parced for HUC12 use.

1.0 WATERSHED CHARACTERIZATION

In this section, key aspects of the watershed are characterized. This is important for later being able to identify the most vulnerable areas and to mobilize resources to implement an action plan. Understanding the characteristics of the watershed involves gathering existing information and data sets from previous planning efforts. It is important to note that this step is iterative and ongoing as new data are generated and projects are implemented and monitored.

To assess the historical and current conditions of the study area, the following existing data sets that characterize the physical and natural features of the watershed were obtained for each HUC-12 subwatershed in the study area:

- Topographic data (LiDAR)
- Relevant waterway locations
- Groundwater levels
- Soils data
- Land uses including vacant land, wetlands, impervious, etc.
- Precipitation records
- Catchment delineations for flood routing

In addition, the FEMA flood maps must be obtained, and the storm of interest must be identified for screening purposes (1-day 2-year, 5-year, and 100-year events as well as the 3-day 25-year storm event to achieve class 4 in the CRS Manual). In developed areas, many sources of data are already available – the key is putting the key datasets in a format that can queried for screening to identify the priority areas of the watershed. Table 6 is a summary of datasets available at cwr3.fau.edu that were used to construct this plan.

This watershed master plan is a drilldown of the larger Walton County TMDL region, which involves 42 HUC 12-digit sub-watersheds (**Error! Reference source not found.**). **Error! Reference source not found.** shows Walton County Drainage Network and the location of urban areas (cities and towns). In **Error! Reference source not found.**, the HUC-12 (031402030403) is highlighted among all the HUCs to help identifying its location. (Figure 3).

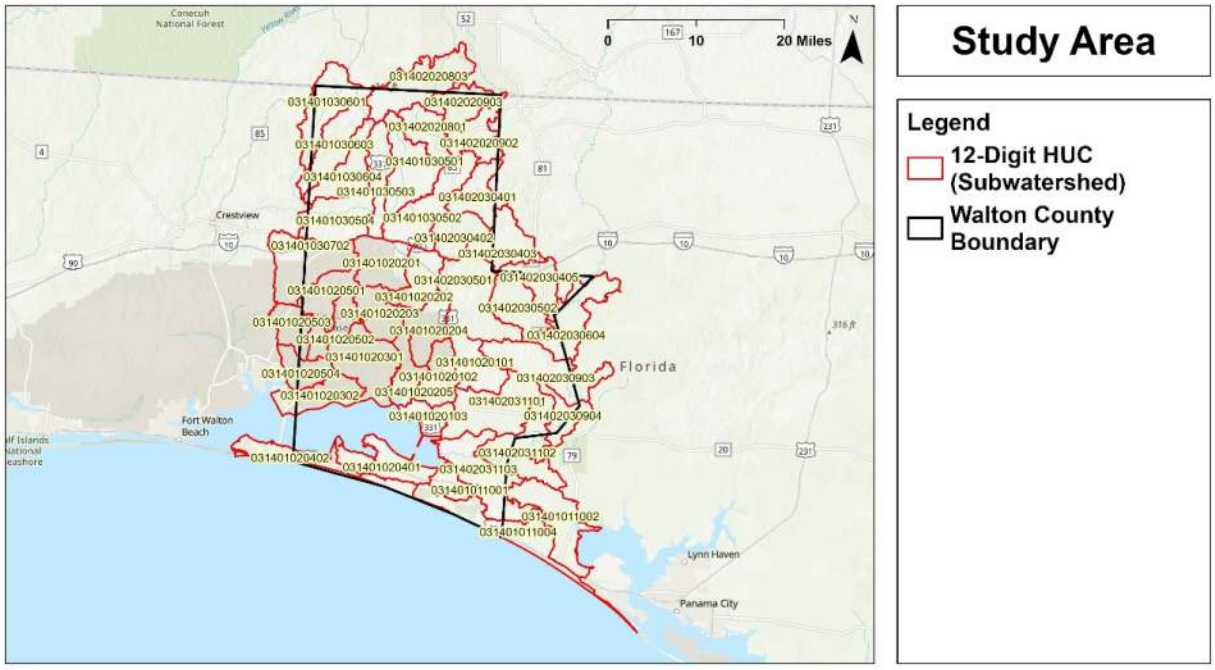

Figure 1. Walton County and all HUCs 12-digit subwatershed, processed by FAU.

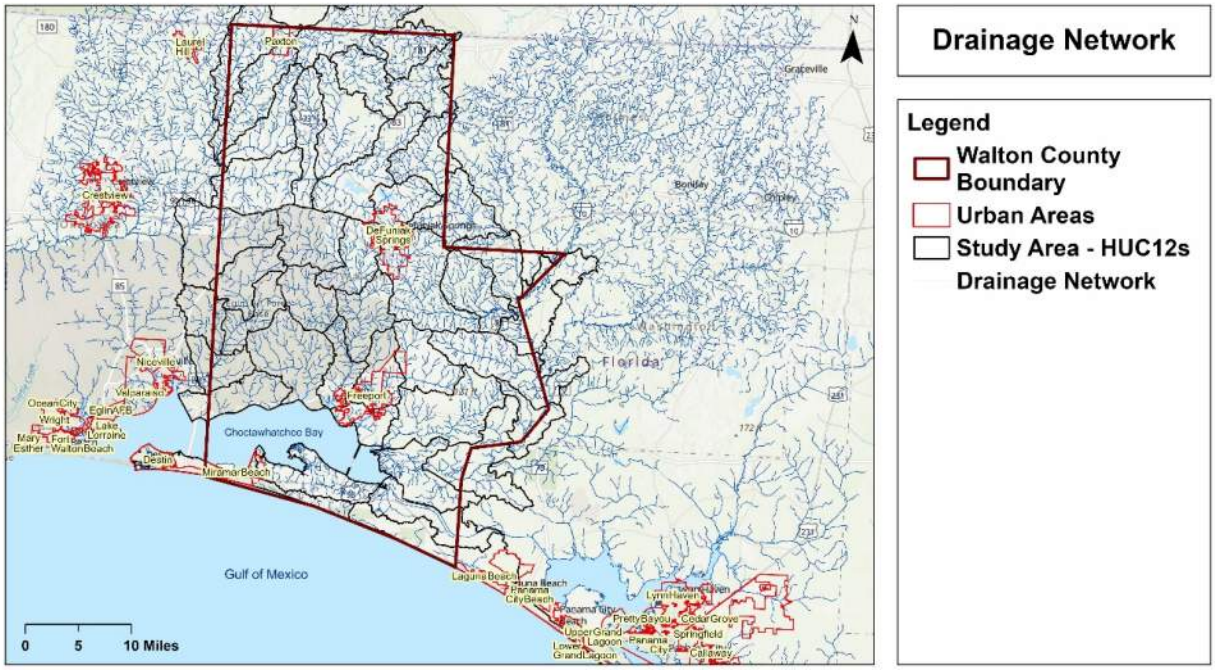

Figure 2. Walton County Drainage Network and urban areas (cities and towns), processed by FAU.

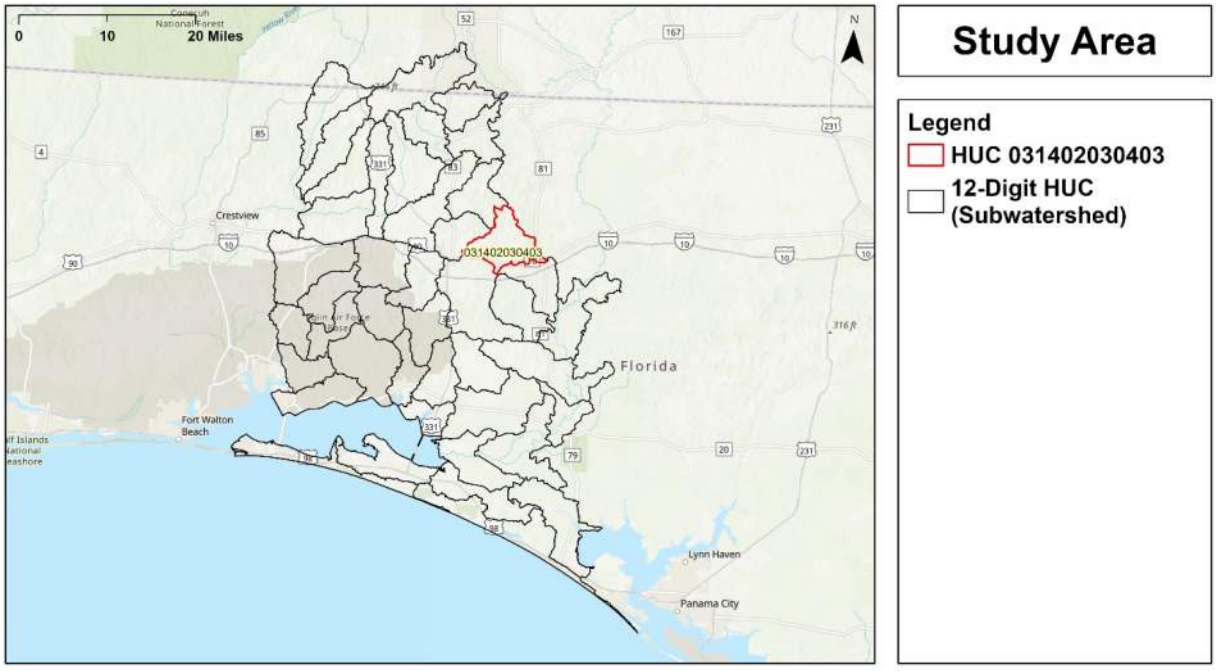

Figure 3. HUC 031402030403 sub-watershed location.

Located in the northwestern region of Florida, Walton County has 1,037.7 square miles of land and it is the 12th largest county in Florida by area, while also sits the highest point in the state,

with a height of 345 feet in its northern end. With a population of 75,305 residents according to the 2020 census and an estimate population in July of 2022 of 83,304, the county has experienced consistent growth within the past several years, driven by factors such as tourism, retirement migration, and regional population dynamics. The county was the residence for 55,043 people according to Census 2010, which leads to a percent change of 36.8% in 10 years, between 2010 and 2020, and a percentage change of 10.6% in two years, between 2020 and 2022 (United States Census Bureau).

The surge in population, particularly in the southern part of Walton County, has resulted in a corresponding expansion of infrastructure to cater to the growing needs. Essential facilities such as potable water systems, wastewater treatment plants, electrical utilities, roads, and schools have been developed to support this increasing population. However, the infrastructure expansion has brought about a significant change in the natural environment. Prior to the existing development , tropical cyclone impacts would be mitigated by natural barriers such as vegetated sand dunes, wetlands, and deserted beaches, which would absorb some of the destructive forces. Now, with the proliferation of costly infrastructure and residential dwellings in coastal areas, these storms pose a higher risk of potential damage. The very areas where development is occurring are becoming more vulnerable to the impact of severe storms, highlighting the importance of considering and implementing adequate measures to address potential storm damage in these coastal regions (Walton County Local Mitigation Strategy Plan, 2015).

Demographically, Walton County presents a heterogeneous age distribution, encompassing a blend of younger and elderly cohorts. The median age of approximately 44 years reflects the presence of both younger families and retirees seeking a serene and picturesque environment. Ethnically, the county' population is predominantly White with smaller yet notable populations of Hispanic/Latino, African American, and other racial/ ethnic groups.

Economically, the tourism sector stands as a dominant force in Walton County, constituting 23.4 percent of the workforce, according to Walton County Economic Development Alliance in 2011, due to its renowned beach destinations, such as Santa Rosa Beach, Miramar Beach, and the New Urbanist Communities of Seaside and Rosemary Beach. Following closely behind is the trade, transportation & utilities sector, accounting for 20.3 percent of employment, while construction stands at 10.0 percent in third place. Education, health care services, and public administration also play significant roles within the top five employment sectors, reflecting the diversified economic landscape of the county (Walton County Local Mitigation Strategy Plan, 2015).

The natural environment in Walton County contributes to its distinctive appeal to visitors and tourists. The county's coastal environment along the Gulf of Mexico showcases picturesque vistas, including white sand beaches, undulating dunes, and coastal dune lakes. These lakes, a rarity worldwide, provide unique ecological habitats. Walton County is also committed to environmental conservation, with designated protected areas comprising state parks, forests, and wildlife

management zones. These preserved landscapes offer abundant opportunities for recreational activities, including hiking, fishing, and birdwatching.

The presence of wetlands and waterways further enhances the natural attributes of Walton County. Various rivers and creeks alongside Choctawhatchee Bay permeate the landscape, fostering diverse ecosystems and serving as crucial habitats for a wide range of wildlife species. This rich natural heritage encourages exploration and nurtures an appreciation for the environment.

DeFuniak Springs serves as the county seat and boasts a diverse economy. Anchored by sectors such as healthcare, education, retail, government services, and a thriving small business community, DeFuniak Springs offers a range of employment opportunities. Surrounded by the natural beauty of forests, lakes, and wetlands, the city enjoys the presence of Lake DeFuniak, a noteworthy natural resource. With a population of approximately 5,100 residents, DeFuniak Springs is a vibrant city featuring a mix of economic activities. The land area of DeFuniak Springs is approximately 12.6 square miles (32.7 square kilometers).

Freeport boasts a diverse demographic profile, and a developing economy. The city is situated along the shores of Choctawhatchee Bay, which provides opportunities for recreational opportunities and supports local ecosystems. Surrounded by lush forests and intersected by waterways, Freeport enjoys a rich environmental setting. In terms of economics, Freeport's economy is in a phase of growth and diversification, with sectors including healthcare, education, retail, and small businesses. The city is also strategically positioned for future economic expansion due to its proximity to major transportation corridors. Demographically, Freeport is a close-knit community with a population of approximately 2,600 residents, comprising a mix of permanent residents, retirees, and individuals seeking a suburban or rural lifestyle. The city reflects a diverse demographic composition, showcasing a variety of cultures, and backgrounds. Freeport occupies a land area of about 13.6 square miles (35.3 square kilometers)

Further along the coast, Miramar Beach stands as a coastal gem known for its tourism and hospitality industry. Luxury resorts, vacation rentals, gourmet restaurants, high-end retail shops, and entertainment venues thrive within this bustling city. Miramar Beach's main attraction lies in its stunning white sand beaches along the Gulf of Mexico, providing endless opportunities for beach activities and water sports. Its boundaries extend into neighboring Okaloosa County, attracting a blend of permanent residents, vacation homeowners, and rental property occupants. Miramar Beach, including its neighboring areas, covers an estimated land area of around 4.7 square miles (12.2 square kilometers).

Continuing along the Gulf Coast, we encounter Santa Rosa Beach. This coastal community is renowned for its vibrant tourism industry, offering a plethora of accommodations ranging from upscale resorts to charming vacation rentals. Its demography reflects a mix of permanent residents, seasonal visitors, and individuals seeking a coastal lifestyle, resulting in a diverse and dynamic community. Santa Rosa Beach spans a larger area compared to other cities in Walton County, with an estimated land area of approximately 31.2 square miles (80.8 square kilometers).

A summary of the existing CRS classifications for the communities in the study area is listed in **Error! Reference source not found.**. No cities in Walton County are listed in the FEMA Community Rating System Eligible Communities.

Table 1. Community Rating System for Walton County. Effective April 1, 2023.

Community #	**Community Name**	**CRS Class Rating**	**Premium Discount for SFHA**	**% Discount for Non- SFHA**	**Status**
120317	Walton County	6	20%	10	Cycle

(Source Data: FEMA)

Figures 12 and 13 is the county-wide report show the current and projected land use for the County. Based on the 2017 future land use for Walton County, only 7.07% of the land use in the county is urban and built up, and water/wetlands makes up 29.16% of the land use. The majority of land is upland forest, with 48.3%, as shown in **Error! Reference source not found.**.

Table 2. Land Use in Walton County (Prepared by FAU from future land use map) versus land use in the entire watershed

Level 1 Land Use-Land Cover Type	**Area (Acres)**	**Percentage of Total**
Agriculture	52958.94669	7.17%
Barren Land	9242.05986	1.25%
Rangeland	40326.66002	5.46%
Transportation, Communication, and Utilities	11815.69287	1.60%
Upland Forest	356796.0541	48.30%
Urban and Built-Up	52194.79061	7.07%
Water	61593.80508	8.34%
Wetlands	153759.9055	20.82%
Total	**738687.9147**	**100.00%**

(Source Data: (NWFWMD 2017)

Walton County has a history of flooding and has implemented various measures for flooding mitigation over the years (see section 1.12 for more details). The County has experienced flooding primarily due to heavy rainfall events and proximity to large water bodies such as the Gulf of Mexico, Choctawhatchee Bay, and numerous rivers and creeks. The topography of the region, with low-lying areas in the coastal areas and wetlands, also contributes to flood vulnerability. The proximity to the ocean (Gulf of Mexico) makes the county vulnerable to sea level rise. Over the years, Walton County has faced multiple flooding incidents, including:

- March 1997: Heavy rainfall led to significant flooding throughout the county, resulting in property damage and road closures.

- April 2009: Intense storms caused widespread flooding, damaging homes and infrastructure and resulting in the declaration of a state of emergency.
- April 2014: Heavy rainfall caused severe flooding, leading to the evacuation of some residents and the closure of roads.

Today, the goal of a stormwater management system in many communities is to keep the community as a place to live and do business while limiting risk from damage due to flooding. The short-term impacts from stormwater include flooding in low-lying areas and standing water in areas with limited soil storage capacity. Less common, but of increasing frequency, is the potential for extensive inundation of some areas, especially low-lying areas, during periods with high groundwater levels and groundwater impacted by sea level rise. As a result, there is a need to understand the economic impact of flooding events and to create cost-effective stormwater infrastructure and policy solutions to protect property. This means preserving as much property and economic activity as possible without disrupting current activity or expending funds on inappropriate projects with limited long-term or social value.

1.1 Surface Topography

Topography is a key parameter that influences many of the processes involved in flood risk assessment, and thus, up-to-date, high-resolution, high-accuracy elevation data are required. In order to meet the requirements for FEMA Risk Mapping, Assessment, and Planning (RiskMAP), 1-meter (2015 to present) and 1/9 arc-second (~ 3-meter) (2010 -2015) LiDAR DEMs were acquired. The 1 m × 1 m LiDAR tiles were kriged to create a topographic map of the study area (**Error! Reference source not found.**). This accuracy meets the 3DEP Quality Level 2 vertical root mean square error accuracy threshold of ±10 cm for FEMA (Arundel et al., 2015). The LiDAR used for this basin was 2016.

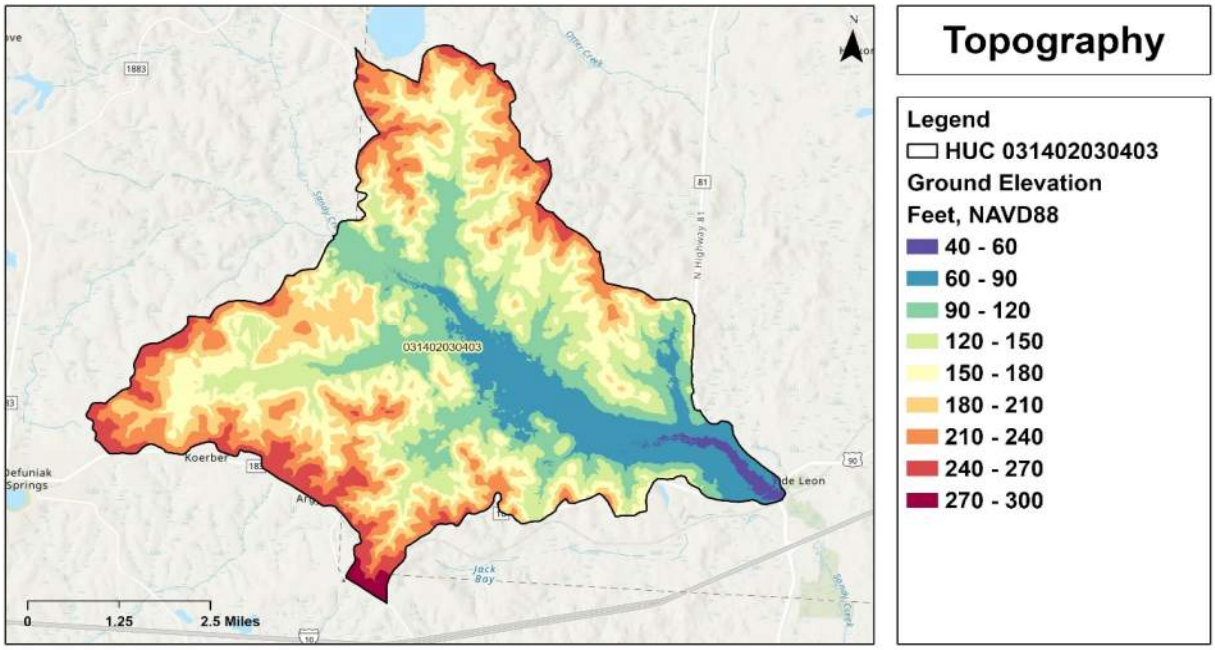

Figure 4. Topographic map of the HUC 031402030403 sub-watershed, processed by FAU.

1.1.1 Geomorphological Considerations

Walton County's coastal area is characterized by the presence of barrier islands, extensive sandy beaches, and coastal dune systems. These features are influenced by the dynamic processes of wave action, tidal currents, and wind-driven sediment transport. The shoreline is subject to natural changes, including erosion and accretion, which significantly shape the coastal geomorphology. Inland Walton County exhibits a mix of wetlands, forests, rolling hills, and rivers. These landforms are influenced by a combination of factors, including underlying geology, fluvial processes, and the region's hydrological regime.

Like many areas in Florida, Walton County is underlain by limestone formations. The specific composition and properties of these limestone formations in Walton County may vary. However, limestone is generally known for its porous nature, which allows for the absorption and storage of water. Underground aquifers within the limestone formations can hold significant volumes of freshwater, contributing to the region's water resources.

For context, the FIRM panel index of HUC 031402030403 sub-watershed is shown in **Error! Reference source not found.**.

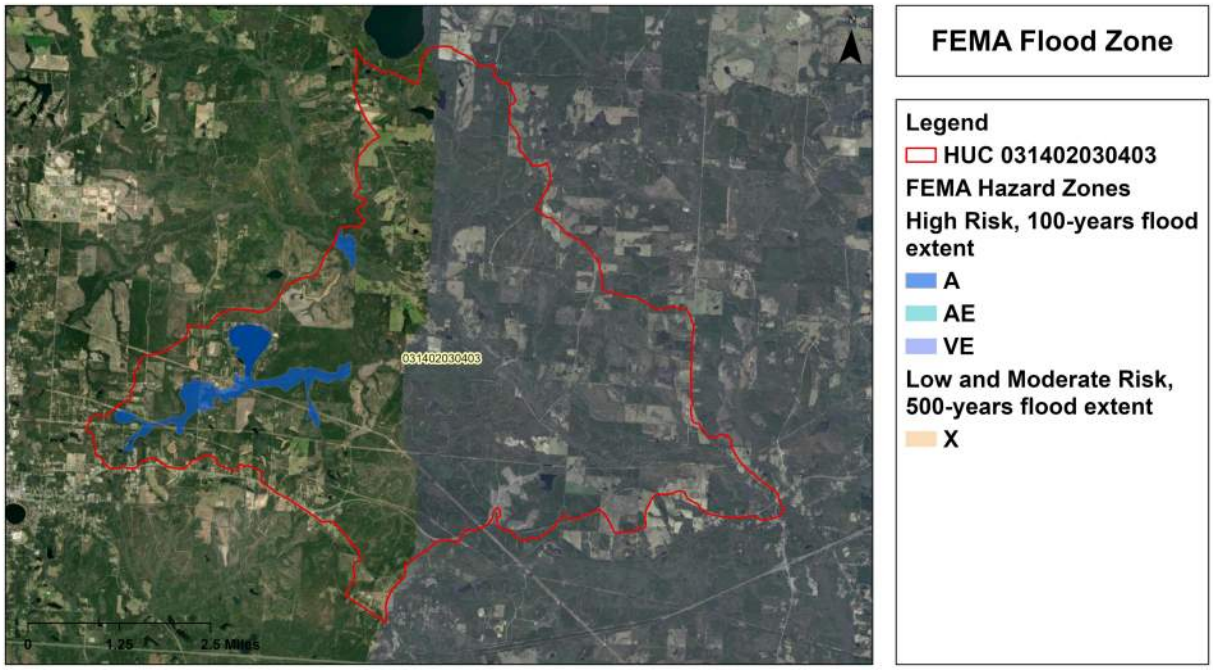

Figure 5. FEMA Flood Zone map (2020) for HUC 031402030403 sub-watershed, processed by FAU.

1.1.2 Waterway Features

In Walton County, Florida, the waterway features are primarily influenced by the presence of rivers, creeks, bayous, and the proximity to the Gulf of Mexico. To the south of Walton County lies the Gulf of Mexico. Sandy beaches, barrier islands, and the open waters of the Gulf itself characterize the coastline along the Gulf. The Gulf of Mexico influences the coastal processes, including wave action, tidal currents, and sediment transport along the shoreline. The combination between sea level rise and King tide would have detrimental consequences for the county costal area, including the sub-watershed 031402030403 as it will reach the area thought Choctawhatchee Bay.

Walton County is home to several rivers and creeks that meander through its landscape. These waterways provide drainage for the inland areas and contribute to the overall hydrological system. Examples of significant rivers in the county include the Choctawhatchee River and the Shoal River. In addition, Walton County features bayous and estuaries that connect inland water systems to the Gulf of Mexico.

Choctawhatchee Bay serves as a vital estuarine ecosystem, where freshwater from rivers and creeks mixes with the saltwater from the Gulf of Mexico, serving as a vital estuarine ecosystem. This unique brackish water environment supports a rich diversity of flora and fauna, including

various fish species, shellfish, migratory birds, and wetland vegetation, contributing to the overall biodiversity of the region. It also plays a significant role in the local economy of Walton County as it supports commercial and recreational fishing industries, providing livelihoods for local fishermen and contributing to the seafood industry, while also offering a range of recreational opportunities for residents and visitors alike, such as boating, kayaking, paddle boarding, and sailing. **Error! Reference source not found.** shows the bathymetry offshore.

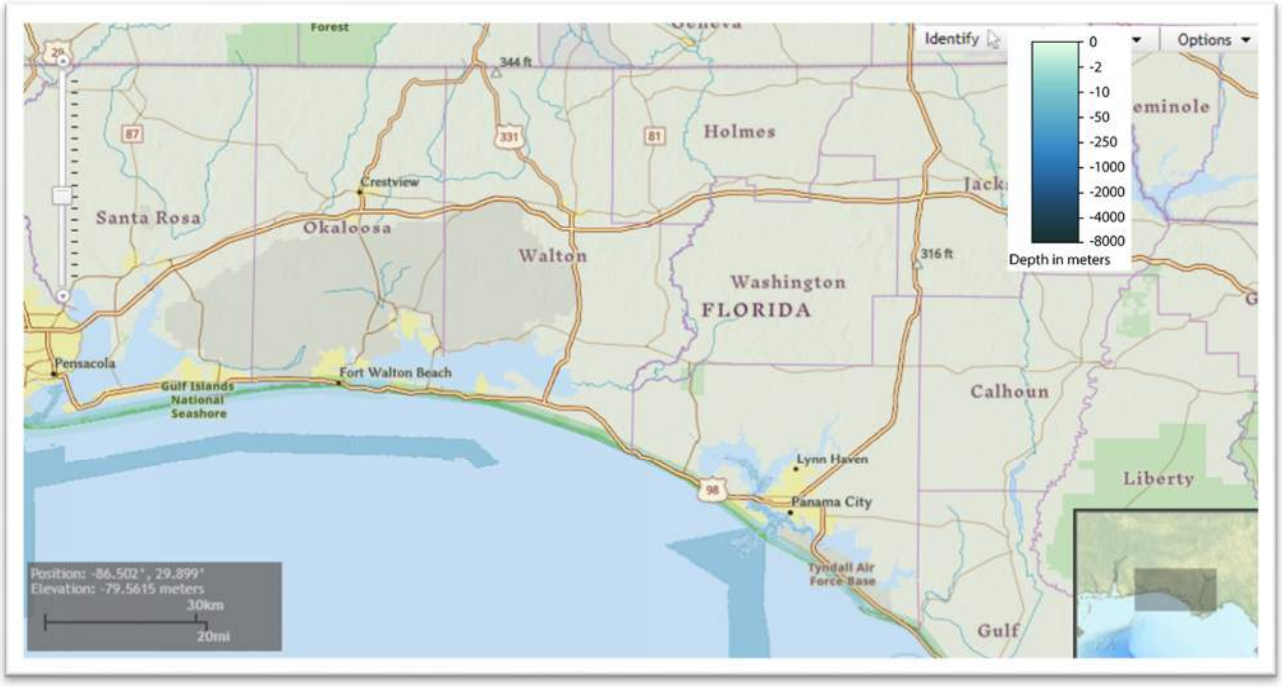

Figure 6. Bathymetry map of the shore of Walton County and surrounding counties of Florida Panhandle. Source: ncei.noaa.gov/maps/bathymetry/

Numerous tributaries exist throughout both the freshwater and estuarine portions of the watershed and can influence the overall hydrology of the area depending on rainfall and regional hydrological conditions. **Error! Reference source not found.** shows the location of all four surface water stations along with ground water stations (wells) and the drainage network of Walton County.

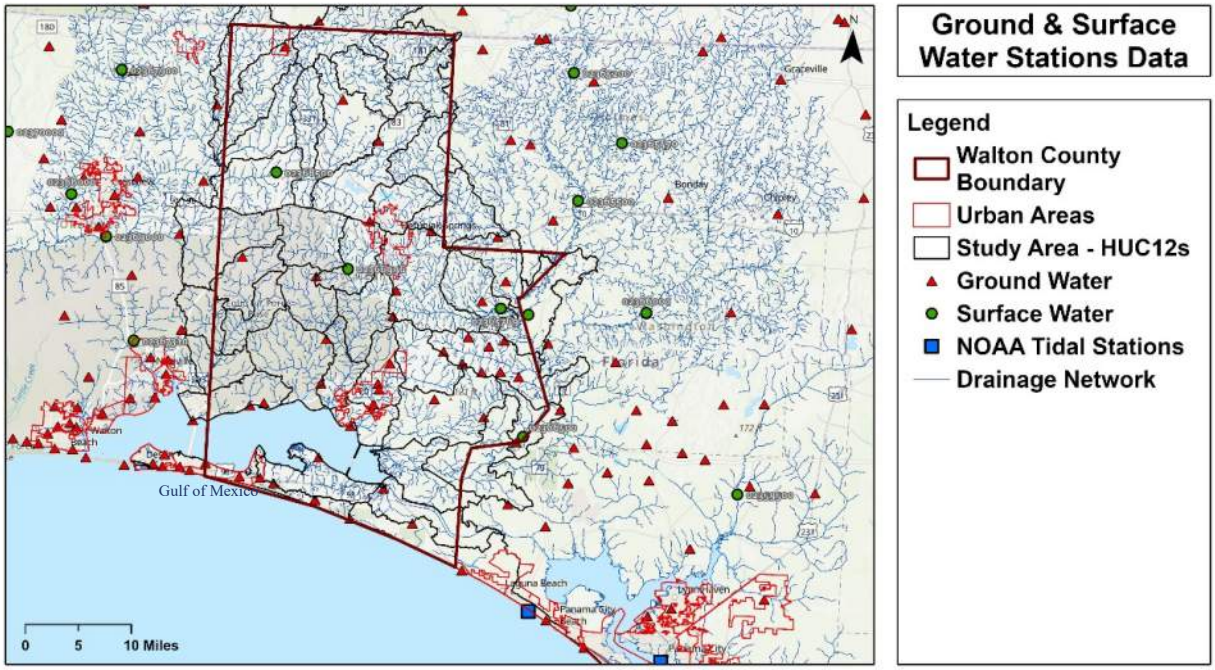

Figure 7. Ground & Surface Water Stations with drainage network for Walton County, processed by FAU.

1.1.3 Hydrologic Boundaries

The geographic area of the subject sub-watershed should be clearly defined to ensure that implementing the WMP will address all the major sources and causes of impairments and threats. Although there is no rigorous definition or delineation of this concept, one way to identify the geographic extent of the watershed master planning effort is to consult the United States Geological Survey (USGS) map of hydrologic units. A hydrologic unit is part of a watershed mapping classification system showing various areas of land that contribute surface water runoff to designated outlet points, such as lakes or stream segments. USGS designates drainage areas as sub-watersheds (including smaller drainages) numbered with 12-digit hydrologic unit codes (HUCs), nested within watersheds (10-digit HUCs). These are combined into larger drainage areas called subbasins (8 digits), basins (6 digits), and subregions (4 digits), which make up the large regional drainage basins (2 digits).

Region>>Subregion>>Basin>>Sub-basin>>Watershed>>Sub-watershed

The HUC 031402030403 has no major rivers and canals, but creeks, which include:

- Sandy Creek

- Bridge Creek
- Padgett Creek
- Parrish Branch
- Black Branch
- Cow Branch

Given that stream flow data are critical for estimating flooding, Figure 8 shows the historical streamflow during June 2022 to July 2023 for USGS 02366966. However, as there are only four surface water station within Walton County, it was necessary to use the nearest station to the sub-watershed 031402030403, which is USGS 02366966 Alaqua Creek Near Pleasant Ridge, FL.\

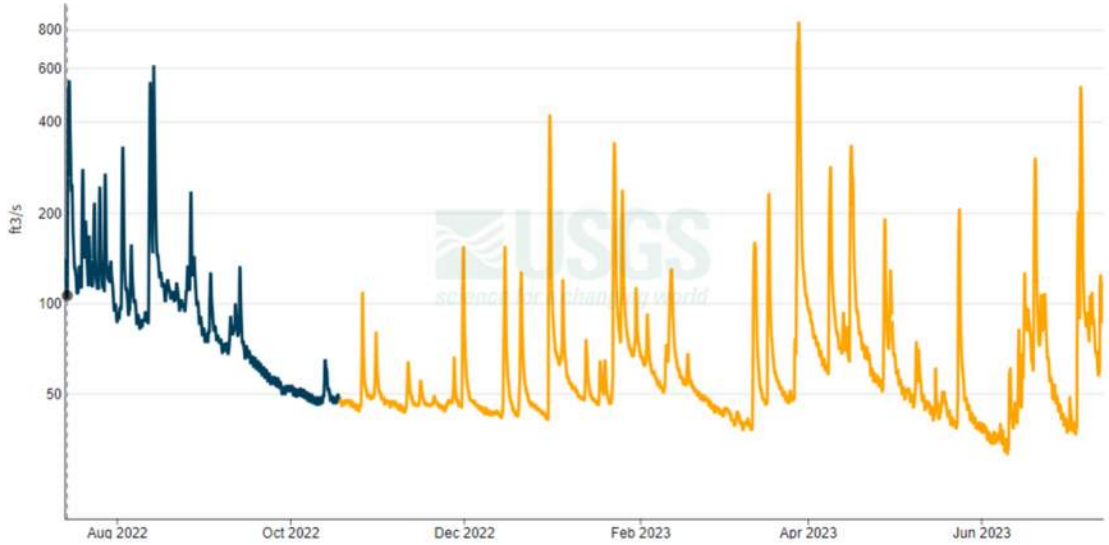

Figure 8. Average streamflow for Alaqua Creek Near Pleasant Ridge, FL (USGS 02366966 Surface-Water, June 2022 to July 2023).
Source: USGS Water Data Services (https://waterdata.usgs.gov/monitoring-location/02366996/#parameterCode=00065&period=P7D).

1.2 Groundwater

In this region of Florida, there is a direct interaction between groundwater and surface water. In addition to low land elevations and topographic relief, the groundwater and surface water are controlled by the canals, rivers, and tides. Since there is a limited number of groundwater monitoring stations, the strong relationship between groundwater and surface water was leveraged to develop a 99th- percentile surface of the water table elevation for mapping purposes. To establish a common date for modeling, the recorded groundwater table elevations were sorted in ascending order to determine the 98th - 100th percentile date of occurrence in Excel®, following the procedure detailed in Romah (2011). This procedure was automated for this effort using a python code to process the groundwater data more efficiently. Outliers and anomalous groundwater levels in the

database are initially identified (e.g. catastrophic storm events) and replaced by region-specific mean values based on observations available from the nearest well. Missing date-specific data are estimated using simple temporal interpolation based on observations available in time. If a station (or monitoring well) data contains large amounts of missing data, it is not used in the generation of the groundwater surface.

In Walton County, the average annual rainfall is abundant, reaching 65 inches at DeFuniak Springs. This rainfall predominantly infiltrates the sand-and-gravel aquifer and eventually seeps into streams or the underlying artesian Floridan aquifer. The county's two major aquifers are the sand-and-gravel aquifer and the Floridan aquifer. While the sand-and-gravel aquifer provides water for rural domestic use and plays a crucial role in water storage and streamflow maintenance, it also serves as a recharge source for the Floridan aquifer. Water from the sand-and-gravel aquifer contains varying levels of dissolved solids, pH, and iron content. The Floridan aquifer, being the primary water supply source, underlies the entire county and yields around 500 to 1,000 gallons per minute from wells, except along the Gulf Coast where the permeability is lower. Recharged by leakage from the sand-and-gravel aquifer, the Floridan aquifer's movement is predominantly southward away from the potentiometric high in northwestern Walton County. It discharges through springs, seeps along the Choctawhatchee River, and by wells. In southern Alabama, the Floridan aquifer is directly recharged by rainfall when it is exposed or close to the land surface. (Bureau of Ecology, 1974).

Once a common time period is determined across the majority of shallow groundwater wells, canal data can be gathered for that common date (and two days prior, in the event the canals were deliberately lowered). Data was obtained from the NWFWMD and processed by FAU at cwr3.fau.edu. Between stations, an ArcGIS tool permits a line to be drawn to replicate the canals and establish points in a gradient between stations. The same is true for the ocean, but it is a constant head boundary. The canals form boundary conditions for the screening tool on the edges of the basin and affect localized groundwater. The tide issue is resolved by using the common date for high tide.

Error! Reference source not found. shows the drainage network of HUC 031402030403 and points out the location of the ground water station in the surroundings. A groundwater-surface layer for the HUC 031402030403 sub-watershed was created using several datasets including water level data from USGS and NWFWMD and groundwater elevation contour maps. The datasets were used to generate a raster surface of the groundwater elevation (**Error! Reference source not found.**).

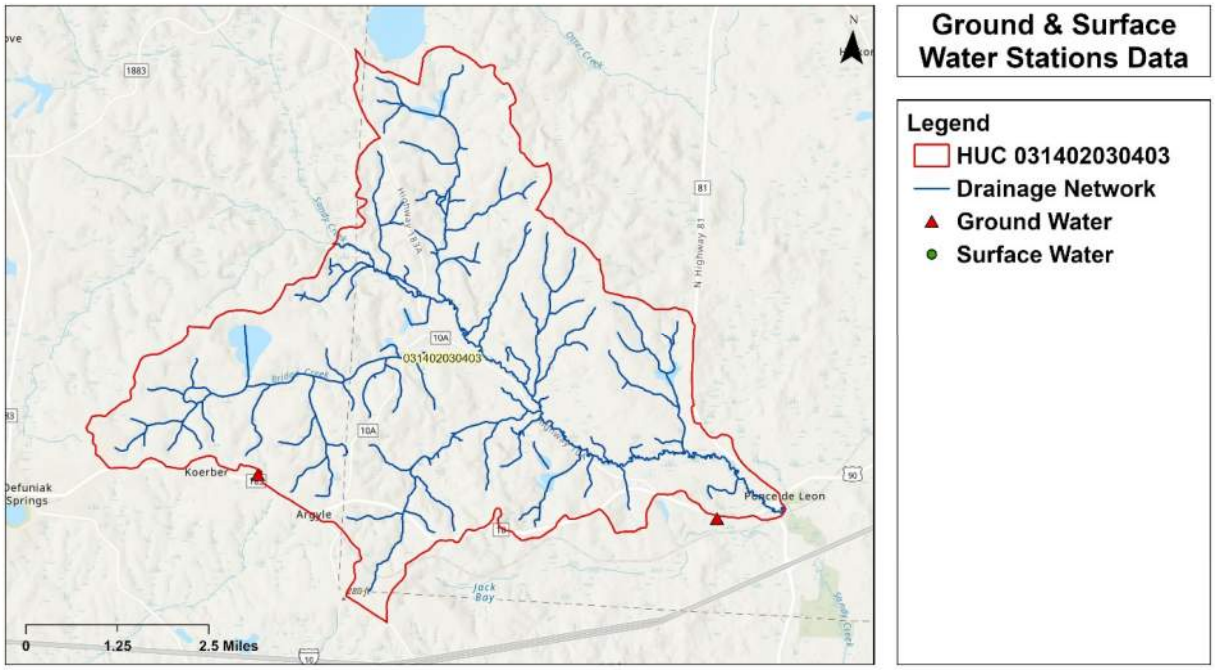

Figure 9. Ground and Surface Water Stations in the HUC 031402030403 sub-watershed, processed by FAU.

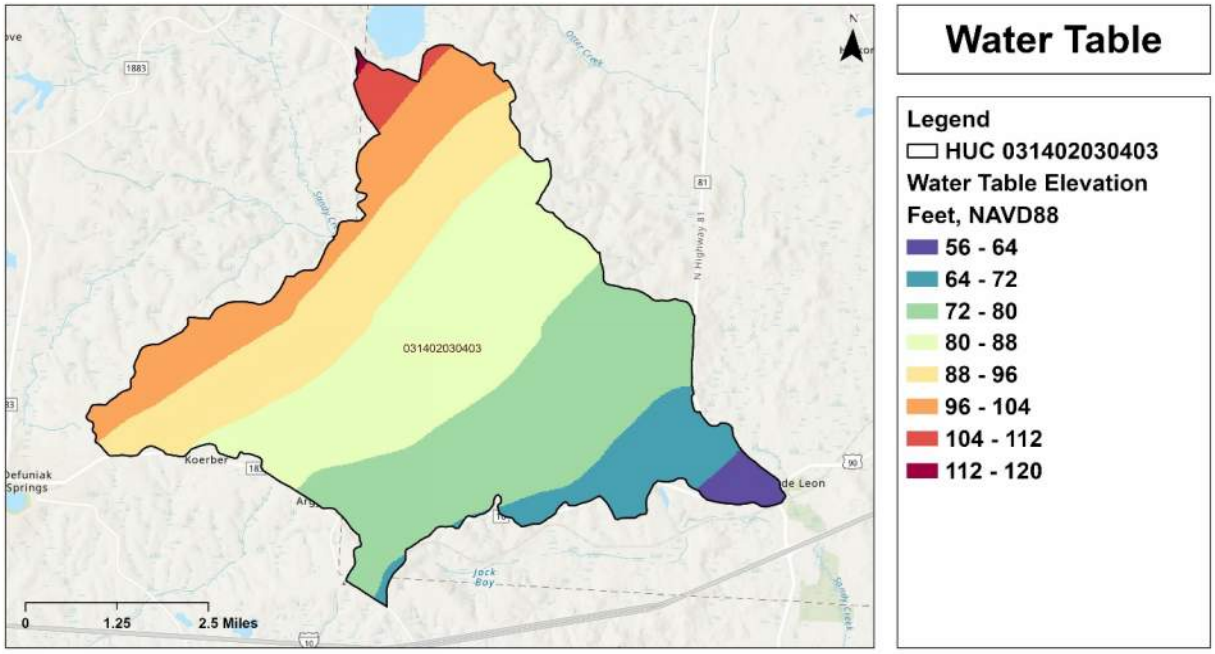

Figure 10. Elevation of the top of the surface groundwater layer for the HUC 031402030403 sub-watershed, created by multiple linear regression analysis – elevation NAVD88, processed by FAU.

1.3 Surface Water/Tides

Historically, surface water and tides have been an important factor in determining how much freshwater is delivered, how fast this water enters wetlands and estuaries, and the quality of that water. Evapotranspiration and rainfall do not coincide in the study area, which makes water supply planning difficult. **Error! Reference source not found.** shows the average precipitation over Walton County for every month of the year between 2011 and 2023.

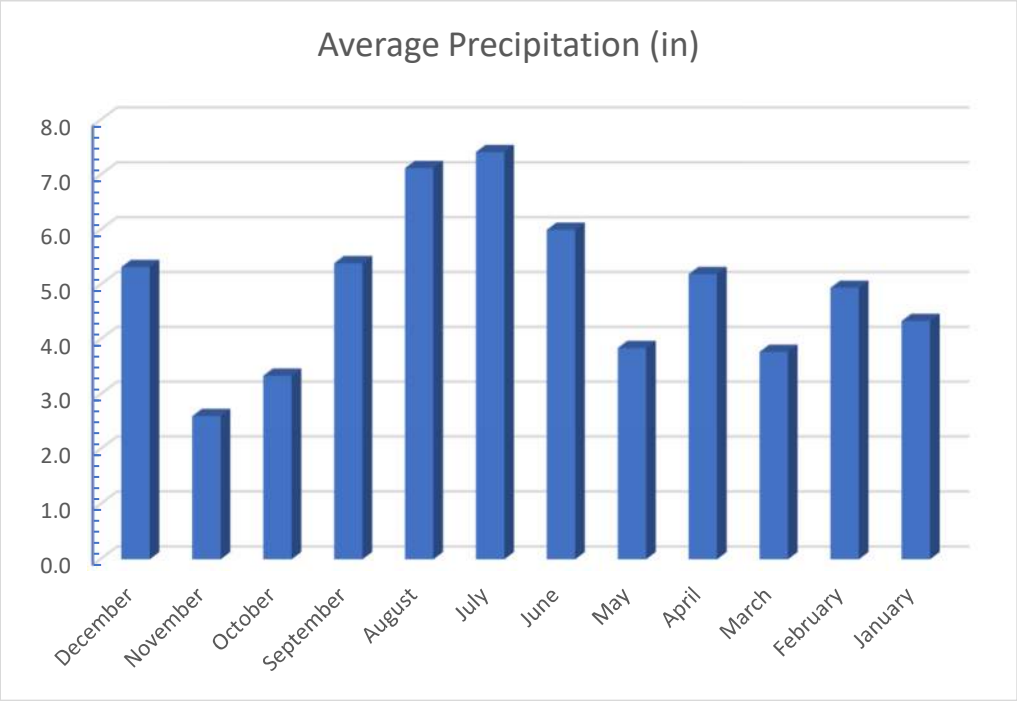

Figure 11. Monthly precipitation in Walton County, FL (2011-2023).
(Data Source: Florida Weather Data, available at https://data.usatoday.com/weather-data/walton-county/12131/1975-04-01/Table/)

While the topography (Section 1.1) and native soil (Section 1.4) create an environment that is highly permeable and capable of infiltrating significant percolation into the soil, changes in land use and land cover have resulted in water falling on impervious areas, where the water collects in pools or runs off rapidly, in direct contrast to the natural condition. This runoff flowing over impermeable regions can lead to larger scale flooding.

Tidal data can be gathered from NOAA tidal gages and other gages monitored by local governments. The location of tide gages is important to ensure they accurately depict tides, as opposed to inland waters. To set a boundary for the coastal areas, the high tide on the common date from 12/03/2018 to 12/10/2018 was selected. **Error! Reference source not found.** shows

the two closest tide stations to Walton County. Since there are no NOAA tide station in Walton County, the Panama City Beach station (8729210) was used.

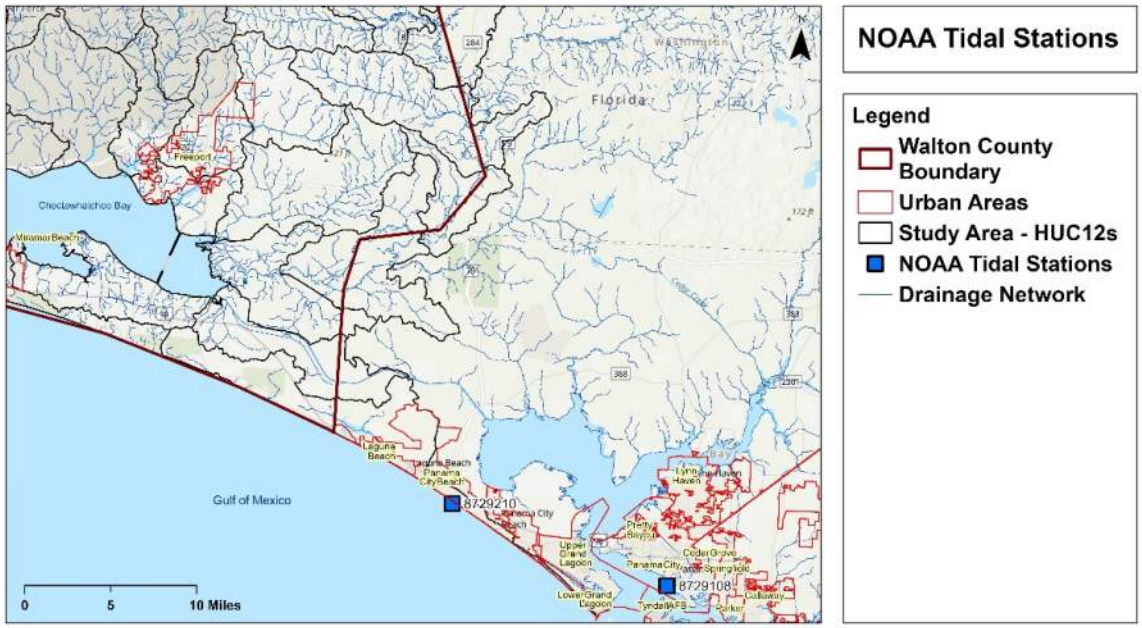

Figure 12. Locations of Florida tidal stations maintained by NOAA near to Walton County, processed by FAU.

1.4 Soils

Soil can store water if there is adequate distance between the topographic surface and the groundwater, and the soil types are capable of absorbing the water. Soil storage capacity is the volume of soil pores in the unsaturated zone that is available to store infiltrated stormwater (Gregory et al., 1998). Throughout Florida, it is common to have large volume storm events that fill the voids in the unsaturated zone as shown in **Error! Reference source not found.**.

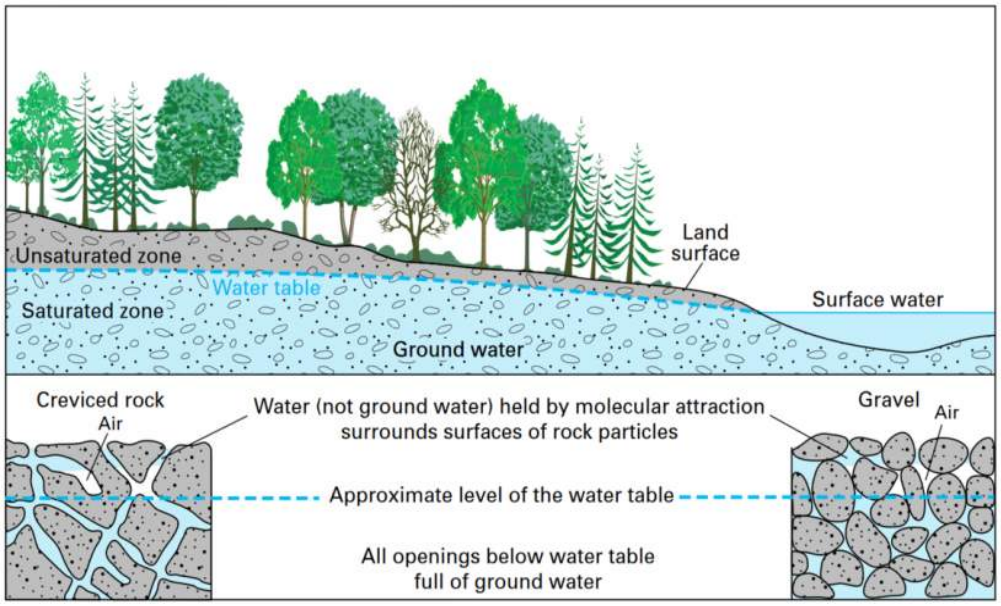

Figure 13. Zones where underground water exists.
Source: USGS, 2020.

The unsaturated zone is the portion of the subsurface above the water table that contains soil/rock and air and water in its pores as shown in **Error! Reference source not found.**. This zone affects the rate at which the aquifer is recharged by controlling water movement from the surface of the land downward towards the aquifer. During rain events, the soil voids fill up quickly resulting in the water table rising to the surface, and the surplus rainfall becomes runoff.

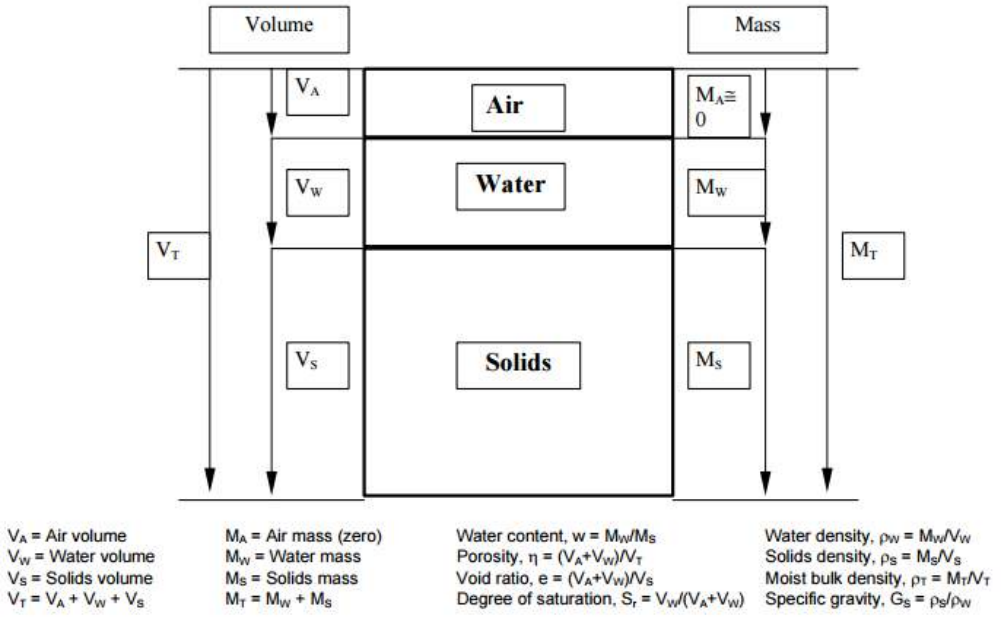

Figure 14. Saturated zone soil phase diagram and definitions.

Source: Gregory et al., 1998.

Soil data is available from the United States Department of Agriculture (USDA) or other agencies in the form of maps that can be incorporated as a GIS layer. The Gridded SSURGO (gSSURGO) dataset from USDA is chosen. This dataset is similar to the standard product from USDA Natural Resources Conservation Service (NRCS) Soil Survey Geographic (SSURGO) database, but is in the Environmental Systems Research Institute, Inc. (ESRI®) file geodatabase format. A file geodatabase allows for statewide or even Conterminous United States (CONUS) tiling of data. The gSSURGO dataset contains all of the original soil attribute tables in SSURGO. All spatial data are stored within the geodatabase instead of externally as separate shape files. Both SSURGO and gSSURGO are considered products of the National Cooperative Soil Survey (NCSS). **Error! Reference source not found.** shows the unsaturated zone found by the difference between the groundwater elevation layer and surface topography.

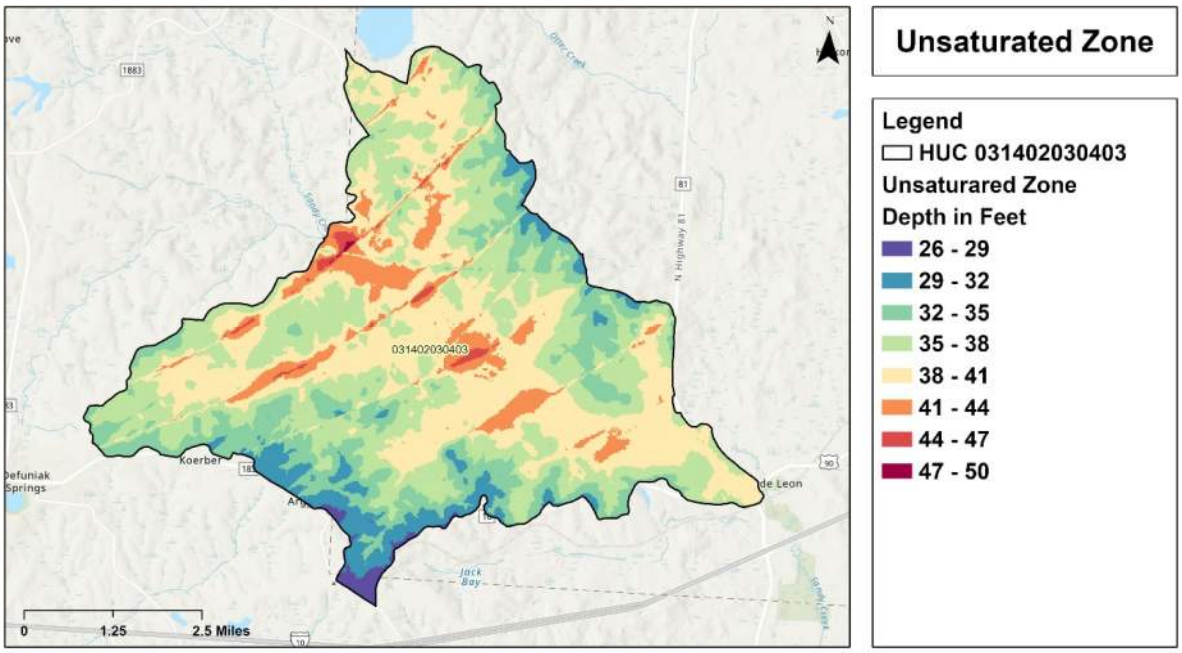

Figure 15. Unsaturated zone map for HUC 031402030403, processed by FAU.

The available water storage from USDA derived for the soil layer (0-150 cm or 0-5 ft) statewide is shown in **Error! Reference source not found.**, which covers most of Florida with a spatial resolution of 10 m. The unit is in cm. As a result of applying this layer to the study area (**Error! Reference source not found.**), the estimated soil storage capacity can be illustrated. A significant portion of the basin demonstrates a moderately favorable soil storage capacity, falling within the range of 32 to 44 feet of remaining capacity.

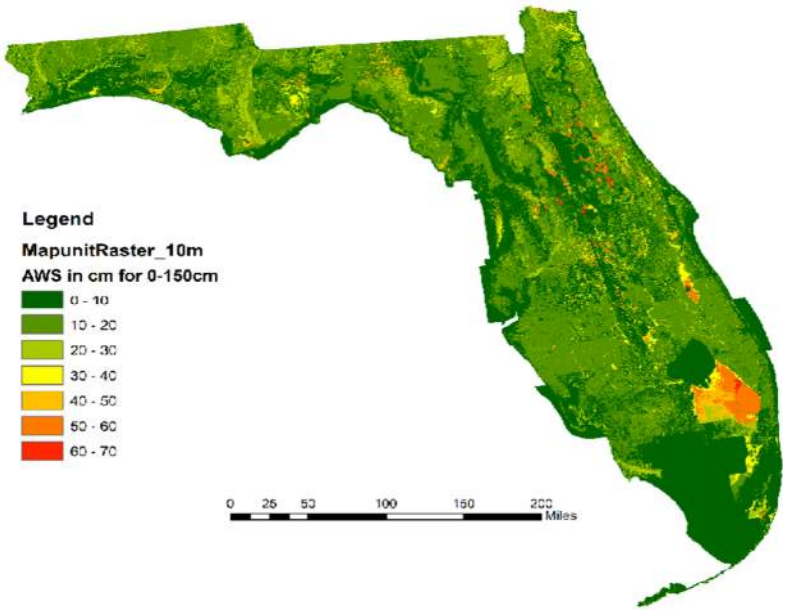

Figure 16. Available water storage derived from the gSSURGO soil database for all of Florida, as processed by FAU.

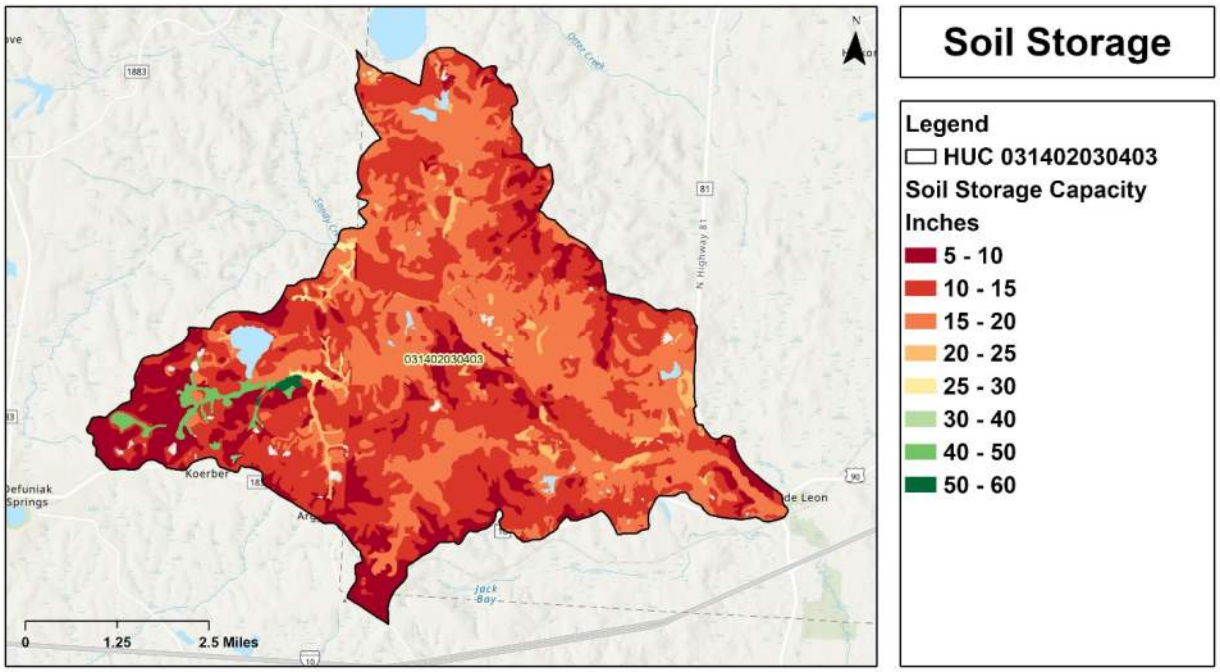

Figure 17. Water storage capacity of soil for the HUC 031402030403, processed by FAU.

Lastly, **Error! Reference source not found.** shows the water holding capacity for the basin, which refers to the capacity of a particular soil texture to retain water against the force of gravity.

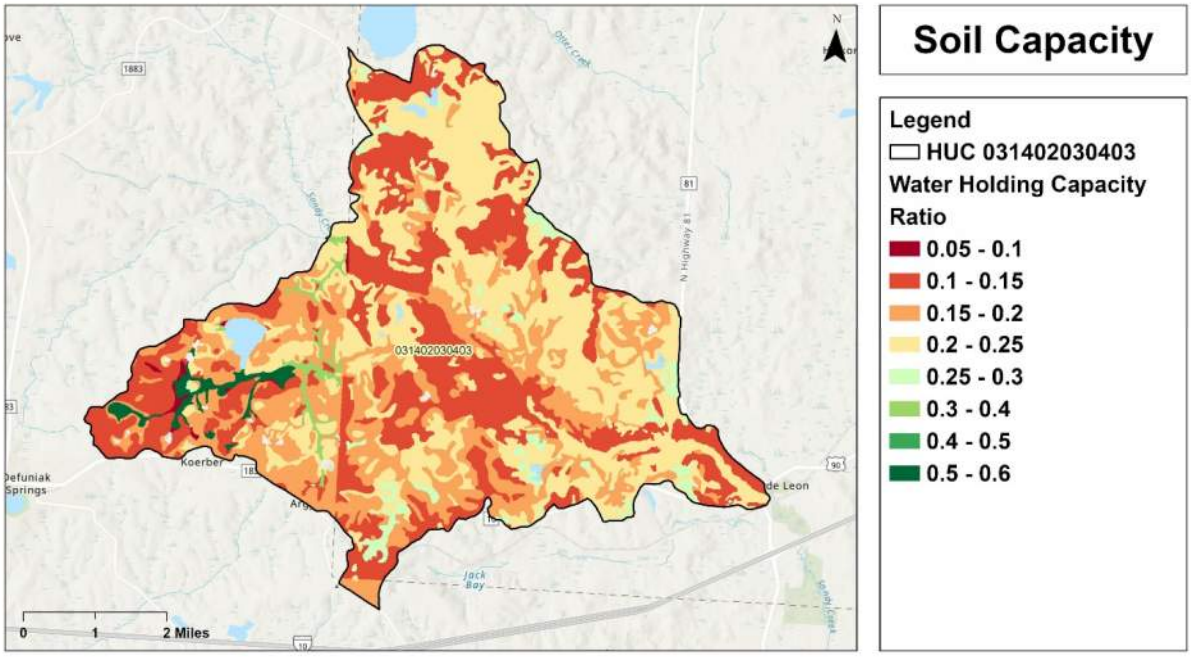

Figure 18. Water Holding Capacity (ratio) for the HUC 031402030403, processed by FAU.

1.5 Land Cover

The USGS produces the NLCD of nationwide data on land cover at a 30-m resolution with a 16-class legend based on a modified Anderson Level II classification system. NLCD is coordinated through the 10-member Multi-Resolution Land Characteristics Consortium (MRLC) to provide digital land cover information nationwide. For the conterminous United States, NLCD 2016 contains 28 different land cover products characterizing land cover and land cover change across 7 epochs from 2001-2016, urban imperviousness and urban imperviousness change across 4 epochs from 2001-2016, tree canopy and tree canopy change across 2 epochs from 2011-2016 and western U.S. shrub and grassland areas for 2016 (**Error! Reference source not found.**).

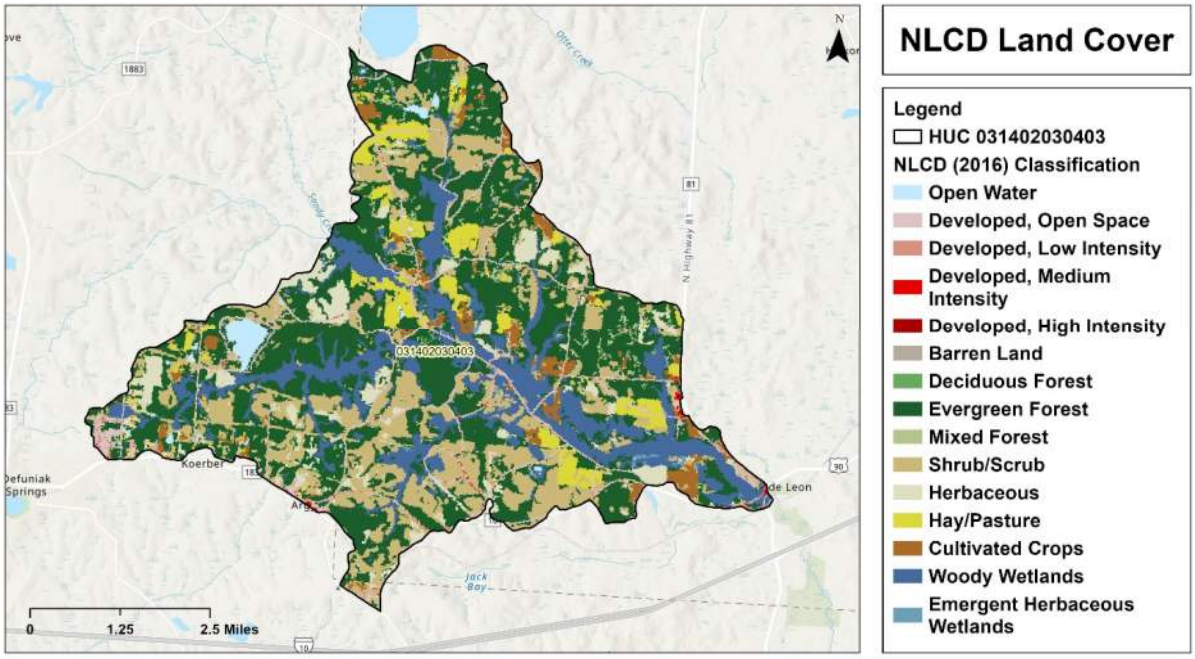

Figure 19. Land use in the HUC 031402030403 (from the NLCD 2016 database), processed by FAU.

The dataset is derived from the Florida Land Use Cover Classification System (FLUCCS), which is digitized by photo-interpretation on county-based aerial photography with varying resolution in the range of 4 in - 2 ft pixel. The NLCD2016 has a 30-meter resolution derived from Landsat imagery. Hence, the NLCD maps appear much coarser and pixelated compared to the 2023 Florida Geographic Data Library (FGDL) (https://fgdl.org/fgdlmap/) maps. A view of the latter is provided in **Error! Reference source not found.**. The future land use maps need to be used for the final land cover, as adjusted for future stormwater improvements set by regulatory standards.

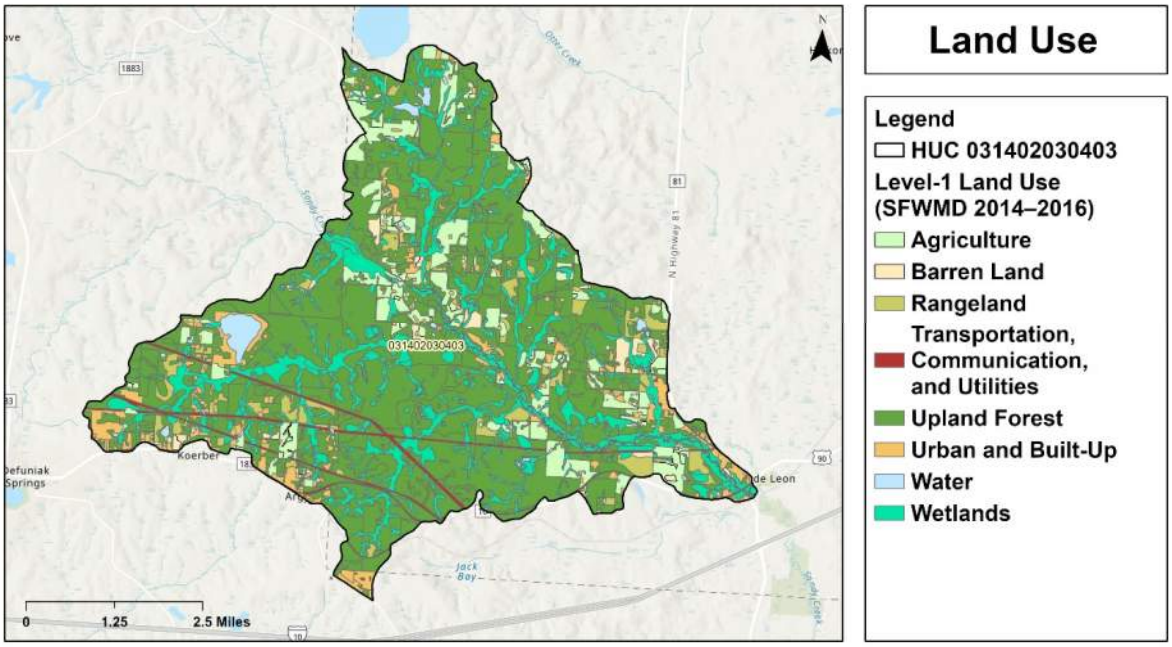

Figure 20. Land use in the HUC 031402030403 (from the 2023 Florida Geographic Data Library (FGDL) database), processed by FAU.

In the HUC 031402030403 sub-watershed, the predominant land cover is upland forest, accounting for 45.38% of the area. Wetland comes in second at 18.82%, followed by Transportation, Communication, and Utilities at 10.39% and water at 10.33%. Developed land constitutes a minor portion, with only 4.04% categorized as urban and built-up, as shown in **Error! Reference source not found.**. **Error! Reference source not found.** shows the roughness of the surface.

Table 3. Land use for HUC 031402030403 subwatershed.

Level 1 Land Use Land Cover Type	**Area (Acres)**	**Percentage of Total**
Agriculture	2331.77	7.40%
Barren Land	251.39	0.80%
Rangeland	896.00	2.84%
Transportation, Communication, and Utilities	3273.12	10.39%
Upland Forest	14300.48	45.38%
Urban and Built-Up	1274.71	4.04%
Water	3254.26	10.33%
Wetlands	5931.85	18.82%
Grand Total:	**31513.58**	**100.00%**

(Source Data: 2023 Florida Geographic Data Library (FGDL) database))

Table 4. Roughness and CN Values for Each Land Use Code.

DOR Code	Use	Impervious %	Roughness
0	Vacant	0	0.4
1	Single Family	29	0.25
2	Mobile homes	21	0.05
4	Condos	60	0.05
7	Vacant –to be developed	0	0.4
8	Multifamily	60	0.05
TH 101	Townhomes	91	0.025
94	Road Right-of-Ways	50	0.08
	Open water	100	n/a
All others	Commercial, etc.	50	0.07

1.6 Precipitation

Rainfall used in the screening tool is based on the SFWMD 3-day 25-year storm, but can be modified for any rainfall event using the accumulated rainfall table obtained from NOAA Atlas 14 Point Precipitation Frequency Estimates (https://hdsc.nws.noaa.gov/hdsc/pfds/pfds_map_cont.html). **Error! Reference source not found.** shows the 3-day 25-year rainfall map based on the NOAA Atlas 14 dataset for the whole state. **Error! Reference source not found.** to **Error! Reference source not found.** rainfall 1-day 100-year, 1-day 10-year, and 1-day 5-year storm event scenarios, in inches.

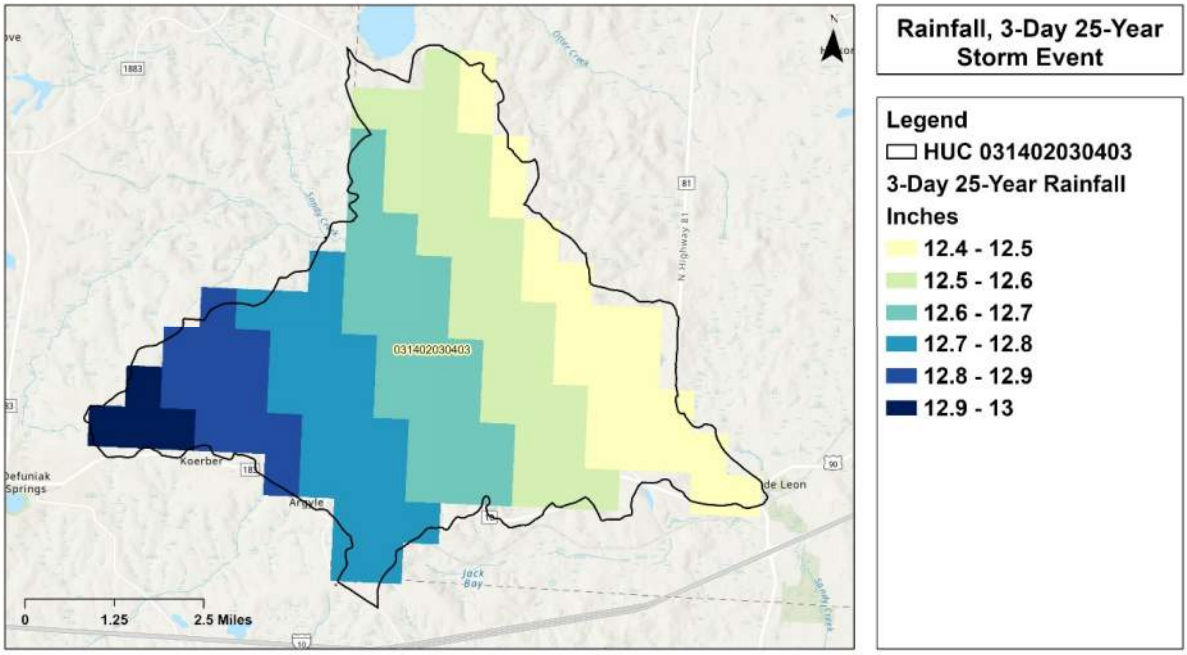

Figure 21. Rainfall distribution map across HUC 031402030403 sub-watershed, for 3-day 25-year storm event, processed by FAU.

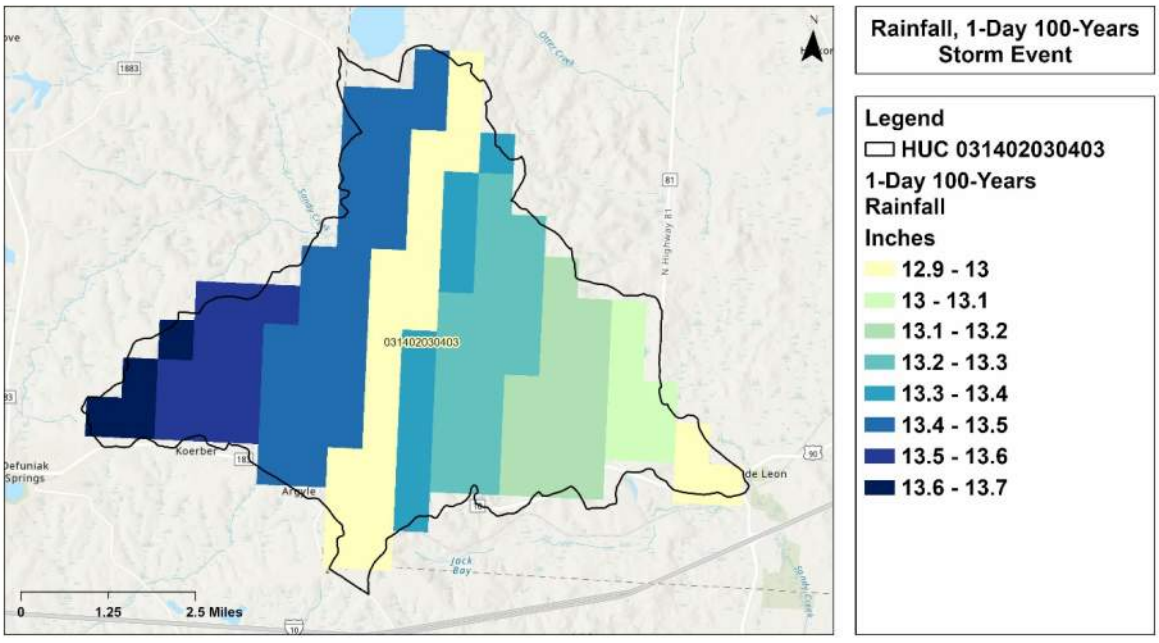

Figure 22. Rainfall distribution map across HUC 031402030403 sub-watershed, for 1-day 100-year storm event, processed by FAU.

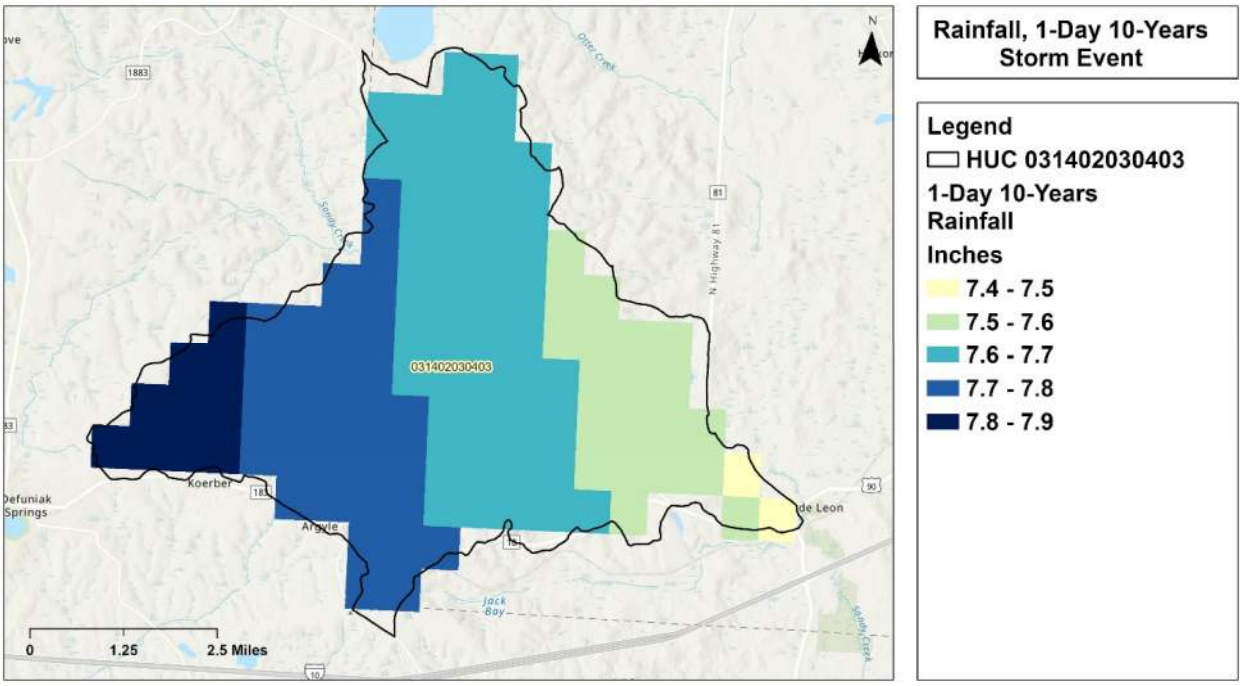

Figure 23. Rainfall distribution map across HUC 031402030403 sub-watershed, for 1-day 10-year storm event, processed by FAU.

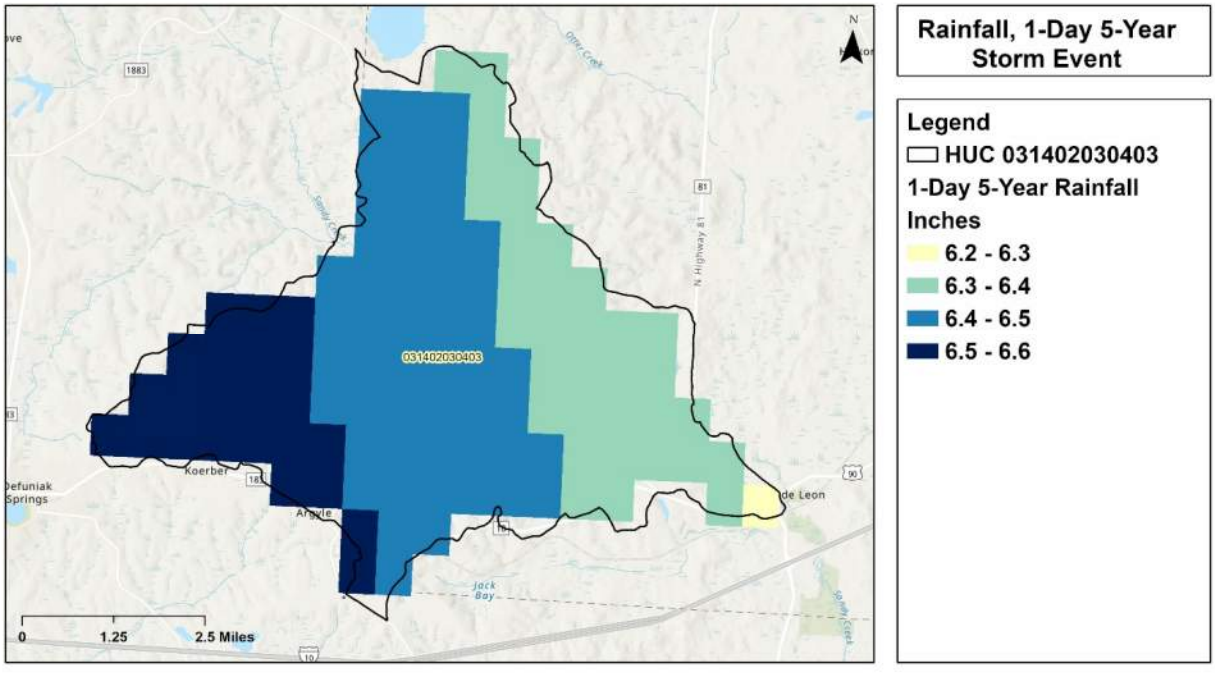

Figure 24. Rainfall distribution map across HUC 031402030403 sub-watershed, for 1-day 5-year storm event, processed by FAU.

1.7 Open Space

Open space is defined as areas that are exempted from development. Generally, this means one or more of the following qualifiers exist:

1. Land that is valuable for recreation, forestry, fishing, or conservation of wildlife or natural resources
2. Land that is a prime natural feature of the state's landscape, such as a shoreline or ridgeline
3. Land that is habitat for native plant or animal species listed as threatened, endangered, or of special concern
4. Land that is a relatively undisturbed example of an uncommon native ecological community
5. Land that is important for enhancing and conserving the water quality of lakes, rivers, and coastal water
6. Land that is valuable for preserving local agricultural heritage
7. Proximity to urban areas or areas with open space deficiencies and underserved populations
8. Vulnerability of land to development
9. Stewardship needs and management constraints
10. Preservation of forest land and water bodies that naturally absorb significant amounts of carbon dioxide

Permanent protection of sensitive areas can provide critical water quality protection and can be achieved through partnerships with landowners, municipalities, land trusts and state agencies. There is limited land in the study area that has been protected via acquisition by federal, state or local agencies, has conservation easements or is designated as wetlands or areas of critical concern. Agricultural land and other land cover will come from the land cover map (in Section 1.5). Added to this will be the water bodies discussed in Section 1.9, which serve a related condition to open space.

1.8 Impervious Areas

Impervious areas do not permit the infiltration of rainfall to groundwater, and because the water cannot infiltrate, it runs off faster. Faster runoff means that flows to water bodies and storm sewers occur faster and with higher peaks. The result is a disruption of the natural and potentially the planned hydrology. Impervious areas include pavement, buildings, and other areas that reduce runoff capacity. In other words, developed areas have much higher imperviousness than open spaces that are natural or agricultural.

The NLCD provides nationwide data on land cover and land cover change at a 30-m resolution with a 16-class legend based on a modified Anderson Level II classification system. Systematically aligned over time, the database offers the ability to understand both current and historical land cover and land cover change to enable assessment of trends. Using the NLCD 2016 dataset, a layer was created by using only three categories out of the 13 to identify impervious areas such as primary roads in urban areas, secondary roads in urban areas, and tertiary roads in urban areas. The new layer was then converted to match the 3-meter spatial resolution from the DEM and the standard State Plane Coordinate system. **Error! Reference source not found.** shows the impervious areas derived from the NLCD 2016 as updated by the future land use map.

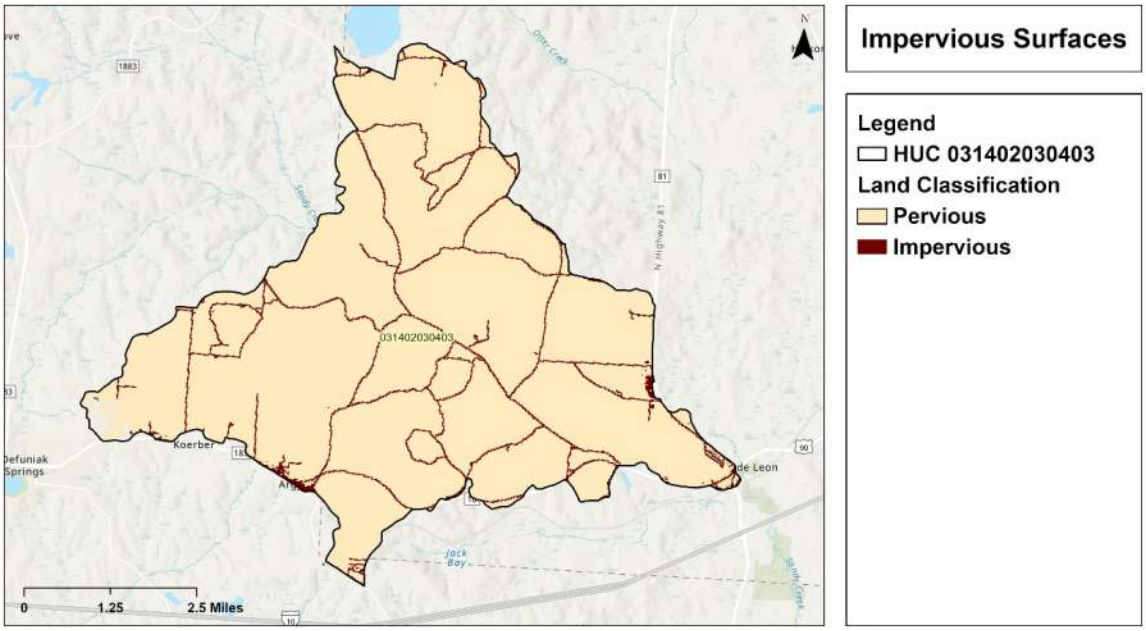

Figure 25. Impervious area map for the HUC 031402030403 sub-watershed, processed by FAU.

1.9 Water bodies

Water bodies were defined in the statewide land use land cover dataset to set soil water holding capacity to zero in model simulations (**Error! Reference source not found.**). Note that tiny water bodies may be missing from the maps. Soils were discussed previously in Section 1.4.

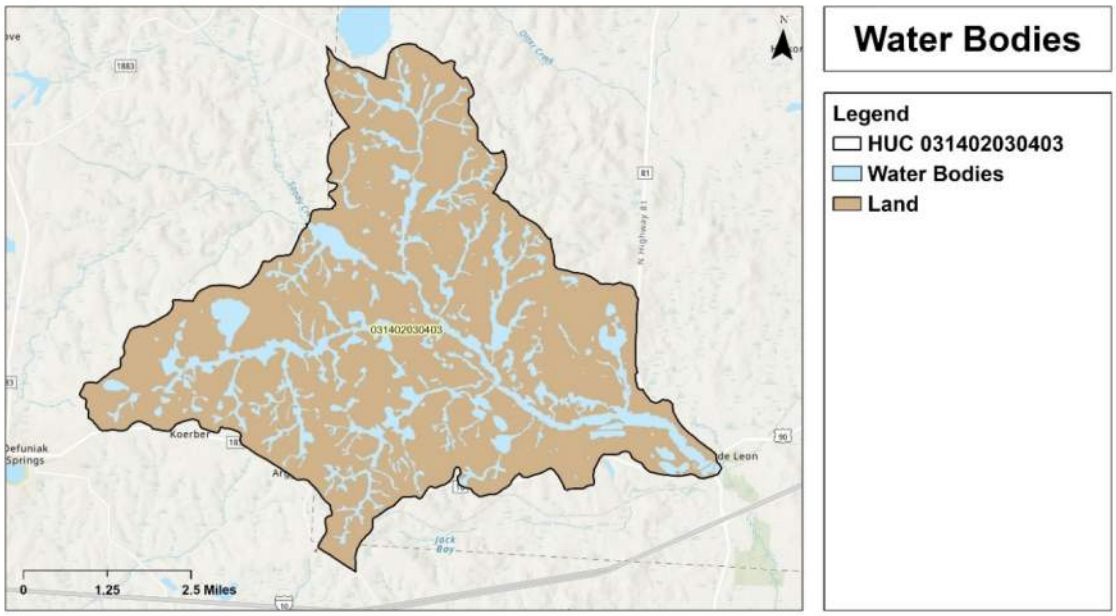

Figure 26. Water bodies map for the HUC 031402030403 sub-watershed, processed by FAU.

1.10. Natural Resources

Understanding the study area's natural resources is critical to identifying potential sources of water quality degradation and areas to designate for conservation, protection, and restoration. One possible goal of watershed master planning is to protect terrestrial wildlife, aquatic habitat, and buffer zones. USGS maintains important sources of information on physical and geographical features as well as soil and mineral resources, surface and ground water resources, topographic maps, and water quality monitoring data. The USDA's Natural Resources Inventory (NRI) (www.nrcs.usda.gov/technical/NRI) is a survey of information on natural resources on non-federal land in the United States that captures data on land cover and land use, soil erosion, prime farmland soils, wetlands, habitat diversity, erosion, conservation practices, and related items. Since 2001, the NRI has been updated continually with annual releases of NRI data from all 50 states. The information provided can be used for addressing agricultural and environmental issues down to the county or cataloging unit level. Therefore, this data can be used to determine erosion and site-specific soil characteristics for certain land uses such as croplands, pasturelands, forestlands, etc., but the data is typically provided as inventories, not GIS layers.

1.11 Demographics

Demographics data is important for determining several key indicators for watershed master planning such as the ability to pay for improvements, social justice issues, land acquisition costs, property/land use, and communication strategies. The US Census has databases at the census tract level. Based on the census data for the study area, **Error! Reference source not found.** outlines population and racial composition demographics.

Table 5. Demographics and Housing Characteristics of Cities and Towns in Walton County.

Demographic Parameter	**Miramar Beach**	**Freeport**	**DeFuniak Springs, City**	**Paxton**	**Rosemary Beach**	**Santa Rosa Beach***	**Walton County**

** Census Designated Place

1.12 Stormwater Infrastructure Inventory

Local community stormwater systems consist of drainage ditches, storm sewers, retention ponds and other facilities constructed to store runoff or carry it to a receiving stream, lake, ocean, or other waterbody. Other man-made features include yards and swales that collect runoff and direct it to the sewers and ditches. When most of these systems were built, they were typically designed to handle the amount of water expected during a 10-year storm. Larger storms overload them, and the resulting backed-up sewers and overloaded ditches produce shallow flooding. Another urban drainage problem occurs in the areas protected by levees. Being in floodplains, they are flat and do not drain naturally, especially when a levee blocks the flow to the river. To drain these areas, channels have been built and pumps installed to mechanically move the water past the levee. Often, these man-made systems do not have the capacity to handle heavy rains or intense storms.

Another challenge with stormwater infrastructure is related to recordkeeping. It is not uncommon for stormwater data to be incomplete in most jurisdictions and completely lacking in others. Quality of data differs from jurisdiction to jurisdiction; some are in GIS formats, while others are paper maps or as-builts that represent the infrastructure at a macroscale level. The condition of the assets may be lacking, and the maintenance history may not be available either. Stormwater assets may have been installed with no records, especially in rural areas, farm fields, and private property.

Walton County passed Ordinance No. 2008-06 that prohibits unauthorized discharges into storm drains or ditch systems. In addition, the Public Works Division is currently running a continuous public awareness campaign aimed at encouraging the adoption of best management practices (BMPs) for managing stormwater runoff. This initiative targets both the business community and the residents of Walton County.

To address the issue of flooding, Walton County has implemented several measures along the years, such as:

- Drainage Systems: The county has invested in the development and maintenance of drainage systems, including ditches, canals, and retention ponds, to manage stormwater runoff and reduce flood risk.
- Floodplain Management: Walton County has adopted floodplain management regulations and participates in the National Flood Insurance Program (NFIP) to encourage responsible development in flood-prone areas.
- Elevation Standards: New construction projects within flood zones are required to adhere to specific elevation standards to minimize potential flood damage.

- Emergency Response: The county has established emergency response plans to assist residents during flood events, including evacuation procedures and the provision of emergency shelters.

Key stormwater assets for the HUC and Walton County are indicated in **Error! Reference source not found.** and **Error! Reference source not found.**, respectively. Stormwater structures and management processes in the county consist of stormwater outfall, water wells, weir, pollutant control boxes, inlets catch basins, pipes culverts, ditch conveyance swales, structures, pipes and open conveyance.

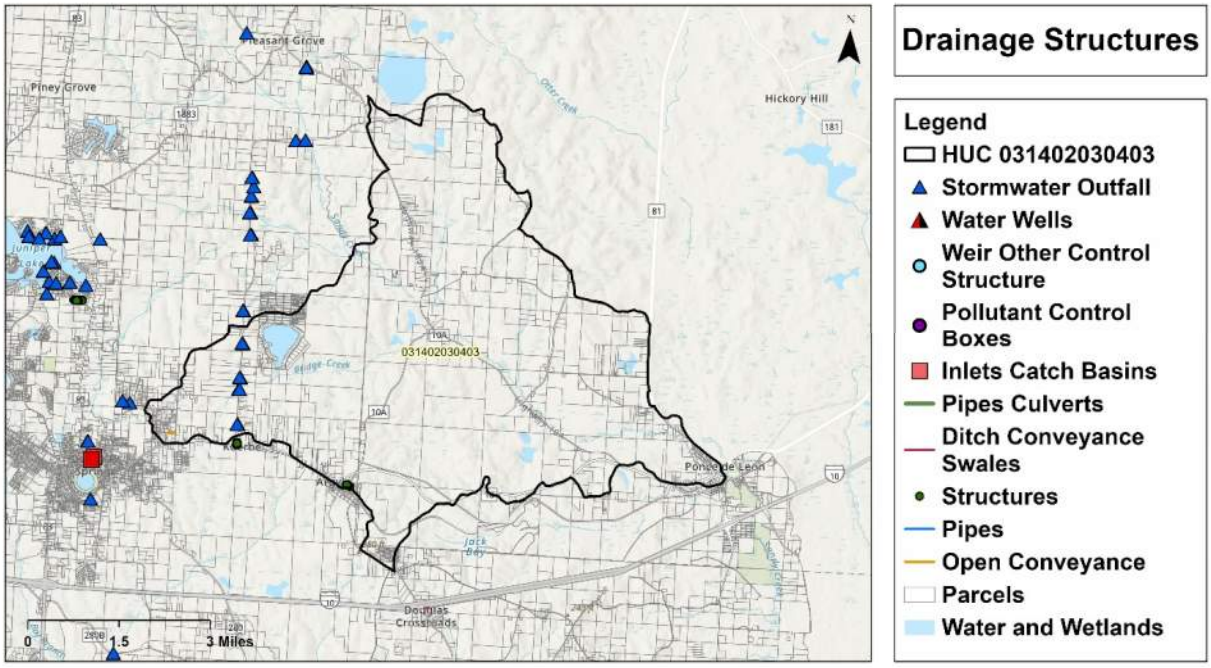

Figure 27. Stormwater Infrastructure for the HUC 031402030403. Processed by FAU.

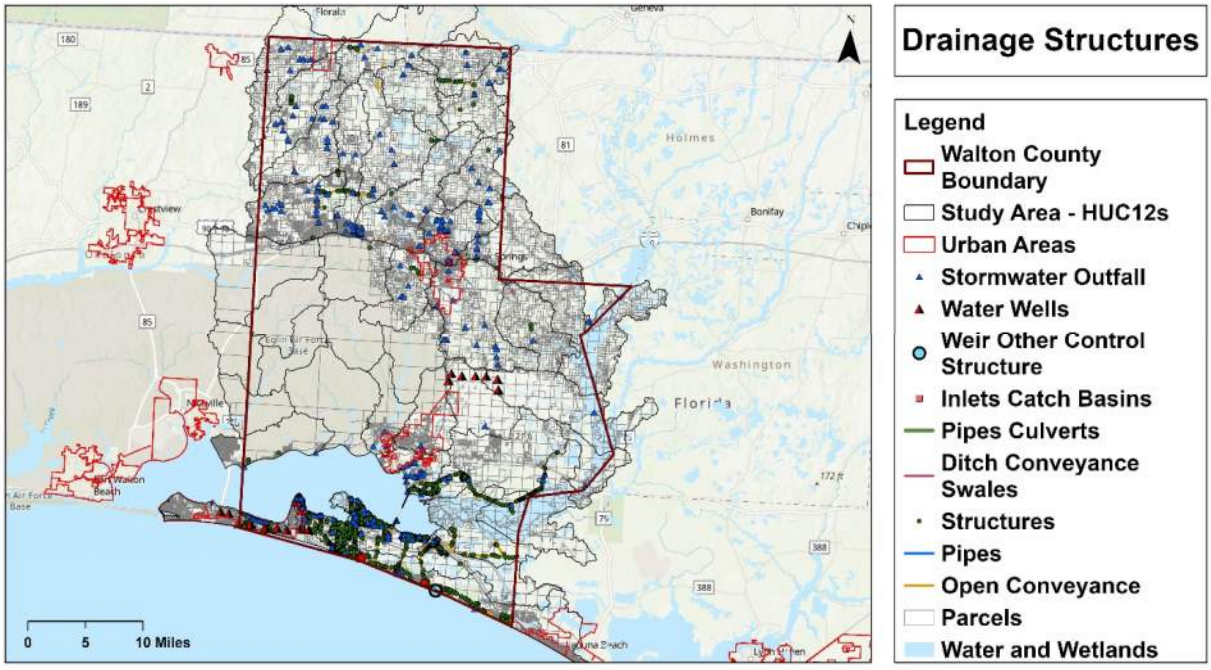

Figure 28.Stormwater Infrastructure for Walton County. Processed by FAU.

Although nature-based infrastructure might be installed, it is not certain. The stormwater system must maintain compliance with the stormwater regulations, which requires record-keeping, policy development, inspections and maintenance. The goals of such stormwater management may include:

- Best landscape practice;
- Control car washing contribution to pollution;
- Enforce the Stormwater Pollution Prevention Plan (SWPPP) by site evaluation, assessment, erosion and sediment controls, preventive maintenance, certification and inspection reporting for construction sites and city planning;
- Implement a hazardous material elimination system;
- Eliminate illicit dumping;
- Proactive and reactive catch basin inspections and maintenance;
- Street sweeping to control debris;
- Maintain swales to help prevent stormwater pollution flooding.

1.13 Data Gaps

FAU has developed comprehensive databases to address the information needed for the vulnerability assessment. These are included in **Error! Reference source not found.**. The data

can be used to model the impacts of flood routing during the storm of interest. As a result, the modeling pieces (discussed in Chapter 2) will include the following:

- Flood response model results (Cascade 2001)
- Flood risk/hazard mapping
- Vulnerability assessments to identify areas of concern for future repetitive losses

There is only one data gap for the area – existing stormwater infrastructure records are incomplete. However, for the purposes of this plan, this data gap does not limit the findings as there are two scales: 1) the sub-watershed level and 2) community hotspots. A neighborhood level vulnerability assessment will require the local infrastructure inventory.

Table 6. List of datasets collected by FAU as of List of datasets collected by FAU for the project (12/20/2020)

Data Category	Dataset Name	Original Source	Spatial Coverage/ Resolution	Temporal Coverage/ Resolution	Link to the Dataset on our Server (physical location)	Dataset size and Format	Native or FAU Processed dataset

2.0 ASSESSMENT OF VULNERABLE AREAS

Defining flood risk due to compounding hydrographic influences is the central concern of this WMP. Modeling and assessment of vulnerability focused on the combination of a high-water table, heavy rains, and impervious conditions that can lead to localized nuisance flooding events. Through a previous survey with local officials, the number of days of continuous nuisance flooding that the public will tolerate before that flooding is considered destructive is about 4 days (E Science 2014).

For a large study area, small parts may actually be at risk. The point is to identify where further study might be needed. A screening tool accomplishes this goal applied to the sub-watershed scale to designate areas that are susceptible to periodic flooding events. Utilizing the information collected and analyzed in Chapters 1, analysis of flood vulnerability can be performed.

2.1 Historical and Existing Challenges

Walton County has faced various historical and existing challenges as well as natural hazards over the years. Some of these include:

- Hurricane and Tropical Storms: being situated along the Gulf Coast, Walton County is vulnerable to hurricanes and tropical storms, which can lead to damage to the built and natural environment, as well as poses risks to human and wild life.
- Coastal Erosion: The county's coastline is subject to erosion due to natural processes and human activities. Erosion can lead to the loss of beaches and threaten coastal structures and properties.
- Flooding: heavy rainfall, storm surges from hurricanes, and other factors can cause localized flooding, particularly in low-lying areas. Flood events can disrupt daily life, damage property, and impact transportation.
- Water Quality and Quantity: as in many coastal areas, managing water quality and maintaining an adequate water supply are ongoing challenges. Pollution from stormwater runoff and other sources can affect water quality, and groundwater resources need to be carefully managed to sustain the growing population.
- Wetland Loss: The county's wetlands face the threat of degradation and loss due to urban development and other human activities. Protecting these essential ecosystems is vital for maintaining biodiversity and mitigating flood risks.
- Urbanization and Development: Balancing the demand for development and growth with the preservation of natural habitats and resources is a persistent challenge. Unplanned

urbanization can lead to habitat destruction, increased runoff, and exacerbate flooding risks.

- Land Use and Zoning: Proper land use planning and zoning are essential to address issues related to population growth, infrastructure development, and natural hazard mitigation. Ensuring responsible development practices can help minimize risks.
- Invasive Species: Like many regions, Walton County faces the threat of invasive plant and animal species. These invasive species can disrupt local ecosystems, negatively impacting native flora and fauna.
- Sea-Level Rise: With rising sea levels due to climate change, coastal communities like Walton County's coastal areas are at greater risk of inundation and storm surges during extreme weather events.

The fast growth of the population and urban development in the coastal areas of the county exacerbates effort to protect open space for land percolation of water. While regulations are in place to reduce the influx of stormwater, the challenges will continue with development.

2.1.1 Existing Management Efforts in the Watershed

The county is under Northwest Florida Management District (NWFMWD) jurisdiction, which covers the Florida Panhandle region. The NWFMWD is responsible for managing and protecting water resources in its designated regions, which includes issues related to water supply, water quality, flood control, and natural resource conservation. Local governments have local stormwater utility infrastructure and planning/policy tools to reduce future flood potential. Most of the major projects to date have been focused on addressing the water quality issues and flooding due to extreme rainfall.

2.1.2 Critical Target Areas Identification

By modeling the HUC 031402030403 sub-watershed flood response to a series of rainfall events (plus king tides), and further classifying flood risk as the probability of inundation, it is possible to identify critical target areas. These areas are particularly vulnerable to flooding and are subject to further study through a scaled-down modeling approach. The screening tool is first applied at the greater watershed level to provide an initial risk assessment focused on the hydrologic response to a rainfall event given the unique characteristics and features of the sub-watershed or study area. The process is discussed later in Section 2.2 with results presented in Section 2.3.

2.1.3 Potential Preservation Areas

Walton County boasts several areas with high biodiversity value. These areas include the unique coastal dune lakes, which support diverse ecosystems and contribute to water quality along the coast. Wetlands are crucial habitats that provide refuge for a variety of plant and animal species while acting as natural water filters. State parks like Topsail Hill Preserve and Grayton Beach State Park are valuable conservation areas with diverse coastal ecosystems. Additionally, preserving the Choctawhatchee River Basin is essential for the biodiversity of the region.

2.2 Vulnerability Maps

2.2.1 Screening Tool

The screening tool utilizes topographic data from various sources (Section 1.1), water table elevations (Section 1.2) and surface water gauges (Section 1.3) downloaded from the NWFWMD DBHYDRO website, tidal information for coastal areas obtained from the NOAA Current & Tides website (Section 1.3), soil maps obtained from the USDA (Section 1.4), and another key dataset as described previously in Chapter 1. The design storms are discussed in Section 1.6. The reason this is critical is that to do any modeling (as required by the CRS program), a screening tool should be used to identify regions with a high risk of inundation based on multiple collected datasets and hydrological models. **Error! Reference source not found.** shows how the GIS layers interface in the tool and how they are combined for spatial analysis.

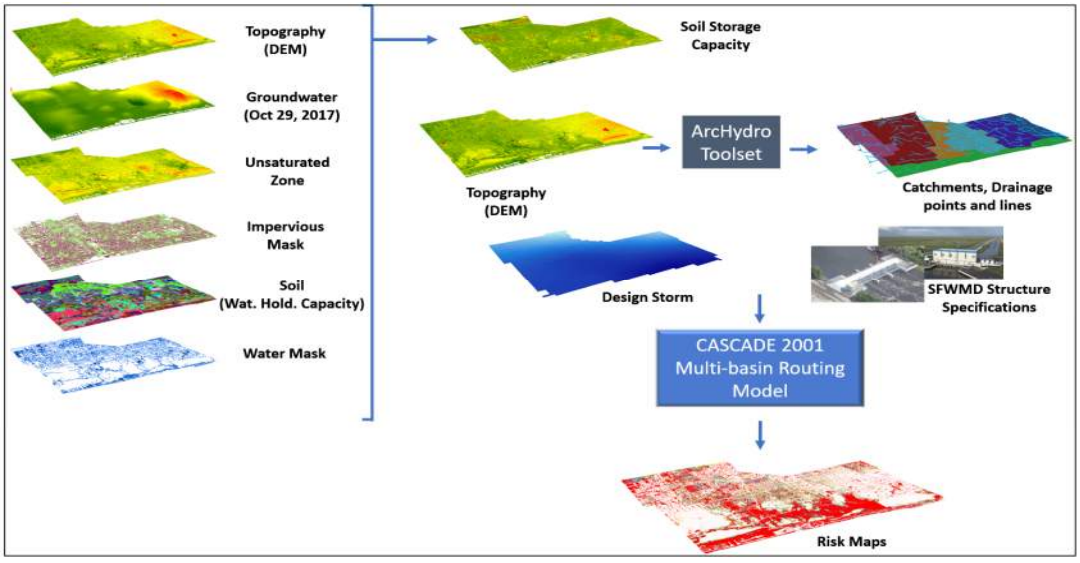

Figure 29. Screening tool methodology for creating flood risk maps.

The model chosen for this screening tool is Cascade 2001, which is a multi-basin hydrologic/hydraulic routing model developed by the SFWMD. The model permits the investigator to run different storm events to determine flooding scenarios. The boundaries are critical for basin studies and must be chosen carefully. The following data layers collected in the prior section are processed to develop the input files for Cascade 2001:

- Topography
- Soils
- Development intensity
- Groundwater elevations
- Surface water/Outlet locations

The software creates a glass box where water rises to a certain level and then decreases. Running the simulation requires defining the basin (HUC or sub-HUC) and input of the following data:

- Area
- Portion of area above a given elevation
- Initial groundwater stage
- Longest travel time for the runoff to reach the most distance point of discharge
- Ground storage as estimated from the USDA gridded National Soil Survey Geographic Database (gNATSGO)

  Ground storage ≈ (Water holding capacity) × (Surface elevation – GW elevation)
  = 2 × (AWS for a soil layer of 0-150 cm) / 150cm × (Surface elevation – GW elevation)

- Available water storage (AWS) for a soil layer of 0-150 cm
- Average amount of precipitation that can be stored in the soil layer

The output from the model is an elevation surface that can be used to develop a flood map for the study area (**Error! Reference source not found.**), which shows the spatial distribution of probabilities of flooding during the modeled 1-day 100-year storm event.

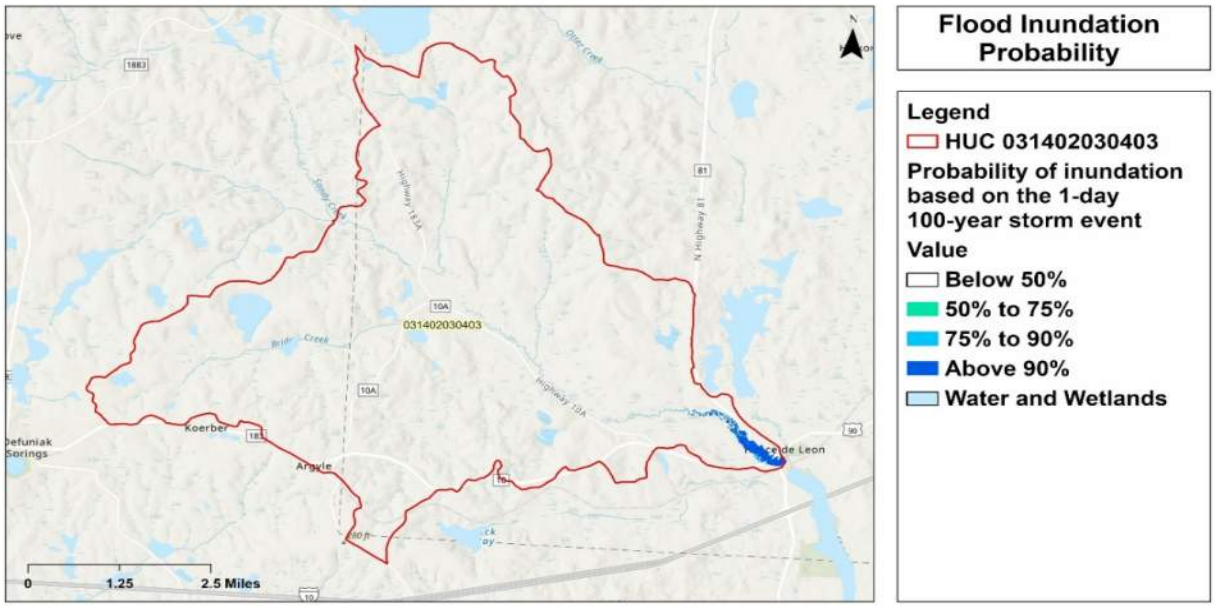

Figure 30. Probability of flood risk map during the modeled 1-day 100-year storm event for the HUC 031402030403, processed by FAU.

2.2.2 Identification of Vulnerable Areas

Given these assumptions and the Cascade 2001 outputs, the goal of this methodology is to produce a spatially-temporally quantified understanding of nuisance-destructive flood potential in the study area given observed values. Risk is a function of compounding geo-hydrological features, namely, surface water, groundwater, topography, build-out, and time of year. A GIS-based algorithm and spatial interpolation generated layers of the greatest observable hydrographic surfaces. These outputs were then compared with high resolution topographic LiDAR data to develop digital elevation models that reflect the observed risk landscape. These models can then be combined into Cascade 2001 to produce vector and volume information, in combination with soils, vegetation and impervious surfaces, allowing the observed model outputs to be extrapolated into a more predictive context.

To evaluate flood vulnerability at this scale, the analysis starts with a binary flooding surface (0 = below 50% chance of flooding; 1 = above 50% flooding) based on output from the screening tool for a specified design storm. Next, attributes of that raster based on "VALUE = 1" query are extracted using *Extract by Attributes* tool. Then the *Batch Project* tool was used to map critical facilities data to the common coordinate system (NAD83 UTM Zone 17N), unit = meters. Then a field was added using *Add Field* for [PriorityTier] = assigned Tier #1-4 value from the DOR codes and [Area_sqmeter]. The critical facilities layers were then merged into a single layer to calculate the polygon geometry for [Area_sqmeter] using the *Merge* tool. Next, *Zonal Statistics as Table* is

used to calculate the SUM of flooded values ("VALUE = 1") within each critical parcel. Output table has fields for SUM (i.e., total # of flooded pixels per critical parcel) and AREA in map units of square meters (since each pixel in the flooding surface has a cell size of 3-meters by 3-meters, each area is equal to the SUM value multiplied by 9 m^2). Using the *Join Field* tool, the SUM and AREA fields are joined to the merged critical facilities layer based on a key attribute, first renaming these fields for clarity (e.g., AREA_FLOODED_3d25y). Once all field data is included, the next step involves using *Export Table* to export the dataset as a CSV file. Note that non-flooded parcels have zero flooded area, so they receive a <Null> value from the zonal statistics tool. To replace null values with zeros, we use *Calculate Field* in the attribute table along with the following Python expression (replacing the respective field name): "0 if !AREA_FLOODED_3d25y! is None else !AREA_FLOODED_3d25y!". Next, the CSV file is saved as an Excel Workbook (.xlsx). The Range is converted to an Excel Table, and the columns are rearranged in the desired order. Finally, the "percent-flooded" columns are calculated as follows:

- PCT_FLOODED_3d25y = ([@[AREA_FLOODED_3d25y]]/[@[TotalArea_sqmeter]])*100
- PCT_FLOODED_1d100y = ([@[AREA_FLOODED_1d100y]]/[@[TotalArea_sqmeter]])*100

After this calculation, the table is sorted to show the higher priority tiers and higher percent-flooded values first. To reduce the number of critical facilities shown in the final table, a filter was created to show only critical facilities with 10% or more flooded area in the parcel during both storm events. Records with duplicate parcel ID numbers were removed from the table. The results of this procedure are discussed in Section 2.4 of this document.

With respect to dams and levees, for purposes of the NFIP, FEMA only recognizes systems that meet, and continue to meet, minimum design, operation, and maintenance standards that are consistent with comprehensive floodplain management criteria. The Code of Federal Regulations, Title 44, Section 65.10 (44 CFR 65.10) describes the information needed for FEMA to determine if a levee system reduces the risk from the 1% annual chance flood. FEMA has accredited levees and Provisionally Accredited Levees (that have a specified timeframe to obtain the necessary data to confirm the levee's certification status). If a levee system no longer meets Section 65.10, FEMA will de-accredit the levee system and issue an effective FIRM showing the levee-impacted area as a SFHA. FEMA coordinates its programs with USACE, who may inspect, maintain, and repair levee systems. USACE has authority under Public Law 84-99 to supplement local efforts to repair flood control projects that are damaged by floods. Like FEMA, USACE provides a program to allow public sponsors or operators to address levee system maintenance deficiencies. Failure to do so within the required timeframe results in the levee system being placed in an inactive status in the USACE Rehabilitation and Inspection Program. Levee systems in an inactive status are not eligible for rehabilitation assistance under Public Law 84-99.

There are no levees/dams listed in the sub-watershed study area.

2.3 Modeling Results

Error! Reference source not found. to **Error! Reference source not found.** are a series of maps that depict risk of flooding in the basin based on the following scenarios:

1. 3-day 25-year storm event. Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (**Error! Reference source not found.**)
2. 1-day 100-year storm event. Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (**Error! Reference source not found.**)
3. 1-day 10-year storm event. Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (**Error! Reference source not found.**)
4. 1-day 5-year storm event. Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (**Error! Reference source not found.**)

In all storm event scenarios, a small portion of flooding is noted at the creek entrance to the HUC. As this basin is not connected to the ocean and its altitude is above 20 feet, the HUC is expected to remain unaffected by sea level rise, therefore SLR scenarios were not computed.

The design storm simulation determined that approximately 0.5% of the HUC total area or 0.15 mi² has a probability of inundation above 50% for a 3-day 25-year design storm. For comparison, approximately 0.5% of the HUC's total area, or 0.15 mi² would be expected to be inundated during a 1-day 100-year design storm. Approximately 0.4% of the HUC's total area, or 0.13 mi², would be expected to be inundated during a 1-day 10-year design storm. Finally, approximately 0.4% of the HUC's total area, or 0.13 mi², would be expected to be inundated during the 1-day 5-year storm. **Error! Reference source not found.** compares the four storm events.

Table 7. HUC 031402030403 expected inundated area by storm event.

Storm Event	Area with probability of inundation below 50% (Sq Mi)	Area with probability of inundation above 50% (Sq Mi)	Area with probability of inundation below 50% (%)	Area with probability of inundation above 50% (%)
3-day 25-year	31.65	0.15	99.5%	0.5%
1-day 100-year	31.65	0.15	99.5%	0.5%
1-day 10-year	31.67	0.13	99.6%	0.4%
1-day 5-year	31.67	0.13	99.6%	0.4%

Processed by FAU.

2.4 Risk and Vulnerability

The screening tool modeling exercise from the prior section identified areas within the communities that are vulnerable to flooding. Higher priority concerns should be those properties or assets that are considered essential and need to be kept in service during a flooding event. All other improvements are local. To help with prioritization, the following is suggested:

- Tier 1 - Critical facility protection (water/sewer utilities, public safety, hospitals, schools, power, shelters)
- Tier 2 - Essential facilities (groceries, pharmacies, roadways)
- Tier 3 - Economic centers (protecting jobs)
- Tier 4 - At risk communities
- Tier 5 - Other urban/suburban property
- Tier 6 - Agriculture/public property/vacant/undeveloped

Error! Reference source not found. outlines the priority of land use based on DOR land use codes from the property appraiser's office and assigns an associated priority level to each parcel. Note that for residential property, identifying at-risk communities (income, age, disability, health) requires a further drilldown to the neighborhood level (i.e. wealthy neighborhoods with few older, poor health individuals would have a lower priority than at risk communities, which generally have lower value housing and denser development). In the latter case, more people are impacted, and those people have less ability to mitigate risk. Based on these priorities, the relative risk priority DOR land use codes were evaluated based on a scale of 1 to 6, where 1 is higher priority (more vulnerable) and 6 is the least priority (least vulnerable).

Having assigned the risk priority from 1 to 6 in the DOR codes and the percentage of the parcel that floods during the applicable design storm, properties that are more critical to the function of the community can be identified. The methodology is to first convert the DOR code priority tier to its inverse scale by the following equation:

Consequence of risk factor = 7 – DOR Code Priority Tier

The flood risk factor from the screening tool is interpreted based on flooding probability. We take all parcels in tiers #1-4 that have a greater than 50% chance of flooding during a particular design storm and calculate the percent of the parcel that would flood during that event. The percentage is converted to a 6-point scale termed as the Flood Risk Factor, shown in **Error! Reference source not found.**.

Table 9. Flood Risk Factor Classification.

Percent of Parcel Flooded	Flood Risk Factor
90-100%	6
80-89%	5
70-79%	4
60-69%	3
50-59%	2
<50%	1

The priority is further developed by assigning 75% of the importance to the consequence of flooding and 25% importance to flood risk, or three times the importance to the consequence of flooding to come up with a composite score as follows:

Flood Risk Factor × 25% + Consequence of Risk Factor × 75% = Composite Score

Example: 1 × 25% + 6 × 75% = 4.75

Those higher priority properties that received the higher composite score are where the mitigation strategies and financial resources should focus first.

2.4.1 Results

Error! Reference source not found. and **Error! Reference source not found.** depict the HUC 031402030403 sub-watershed priority of land uses showing the critical facilities that should receive priority. The first map (**Error! Reference source not found.**) exclusively displays critical facility parcels within the HUC without any flooding. The second map (**Error! Reference source not found.**) overlays critical facilities onto the 1-day 100-year storm event scenario. **Error! Reference source not found.**is a mosaic showing critical facilities overlaid in the 1-day 100-year storm event for the whole county.

Additionally, **Error! Reference source not found.**illustrates the composite score based on 1-day 100-year storm event for the HUC, which is the result of the calculations explained above, pinpointing parcels that should be prioritized. It considers only parcels classified as 1 to 4 tiers, and within the 50% probability of inundation area. Lastly, **Error! Reference source not found.** is a mosaic showing the results for composite score overlaid in the 1-day 100-year storm event for the coastal area of Walton County. As the subwatershed is not coastal, the results based on 5 ft. SLR + 1-day 100-year storm event were not computed for the basin.

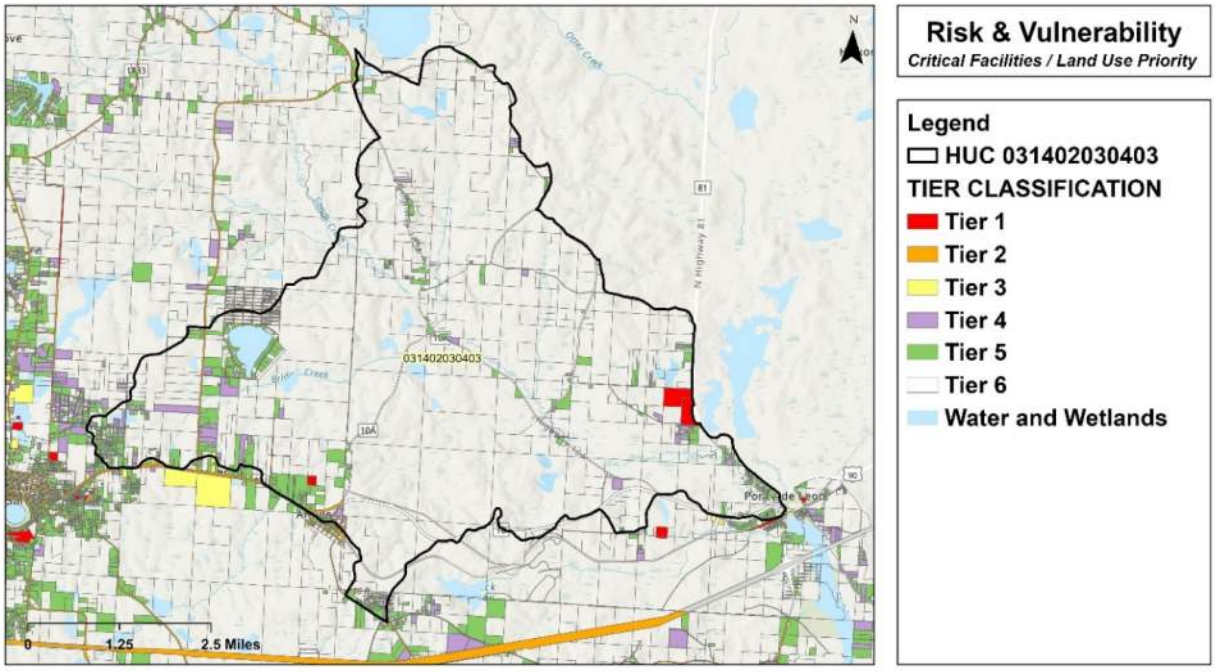

Figure 35. HUC 031402030403 sub-watershed Critical Facilities (priority of land uses) map. Processed by FAU.

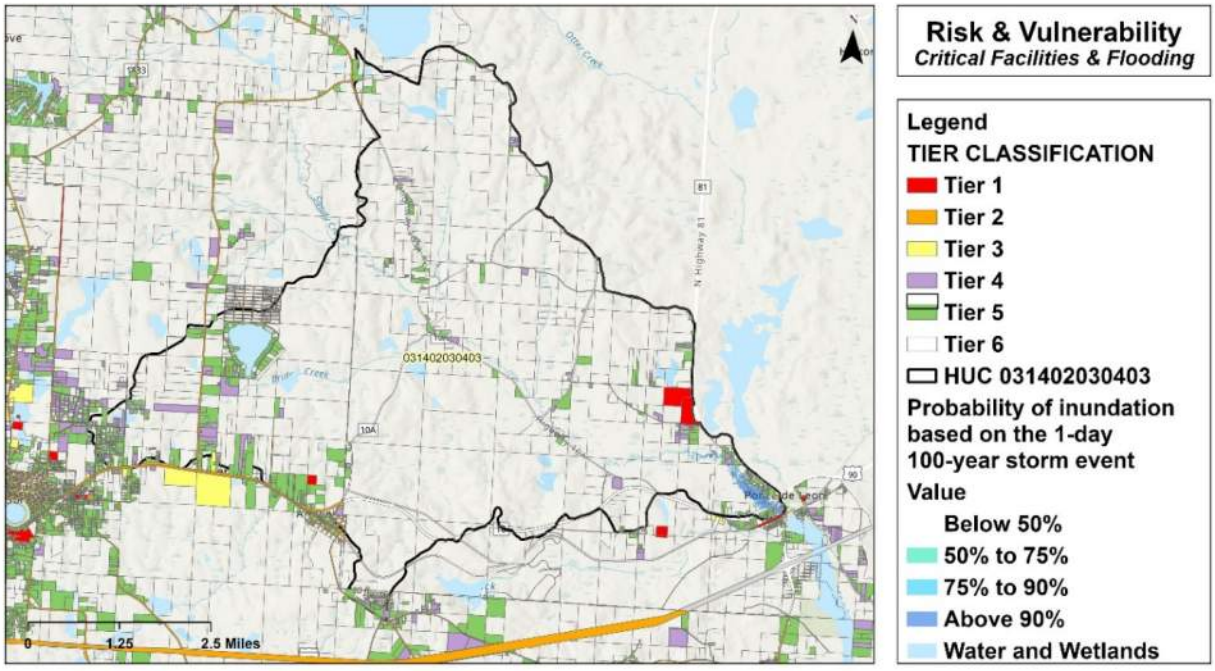

Figure 36. HUC 031402030403 sub-watershed Critical Facilities (priority of land uses) map overlaid on the 1-day 100-year storm event probability of inundation. Processed by FAU.

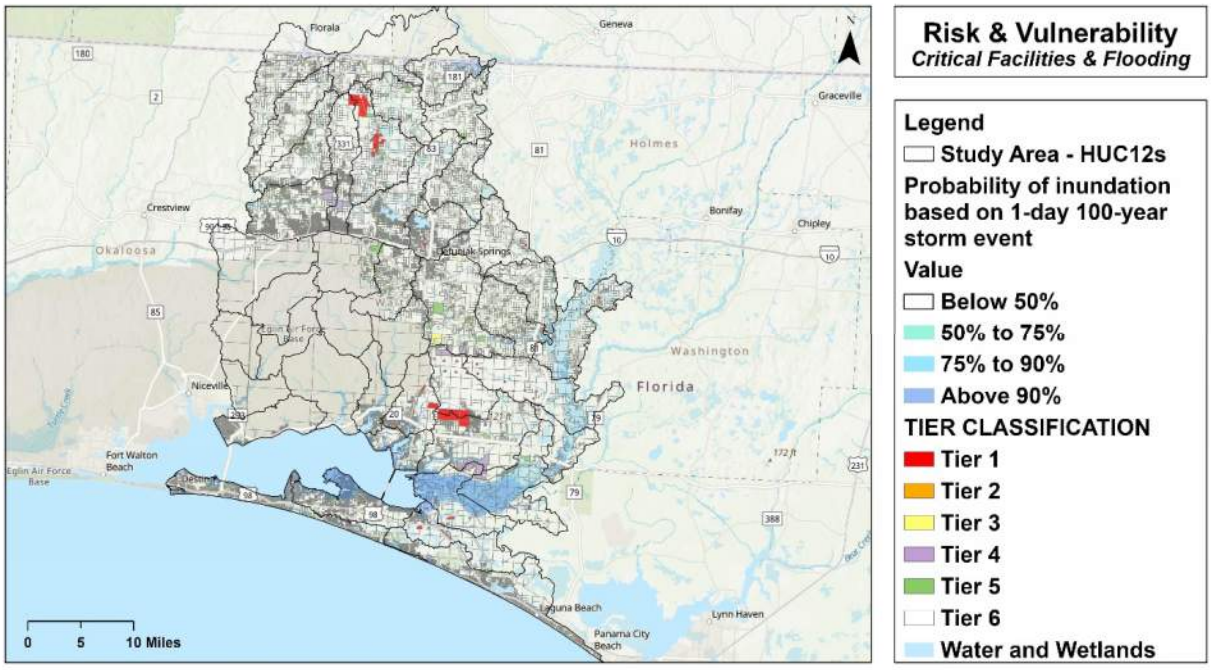

Figure 37. Walton County (mosaic) - Critical Facilities (priority of land uses) map overlaid on the 1-day 100-year storm event probability of inundation for Walton County. Processed by FAU.

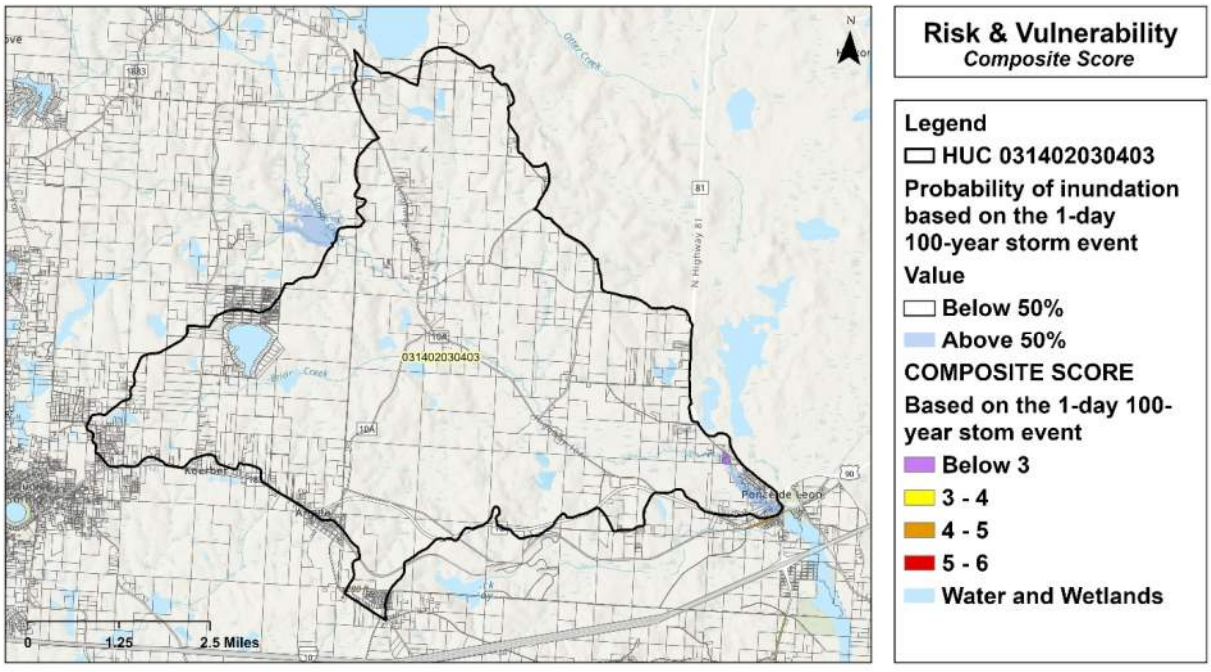

Figure 38. HUC 031402030403 sub-watershed Composite Score Risk map, with calculation based on 1-day 100-year storm event. Processed by FAU.

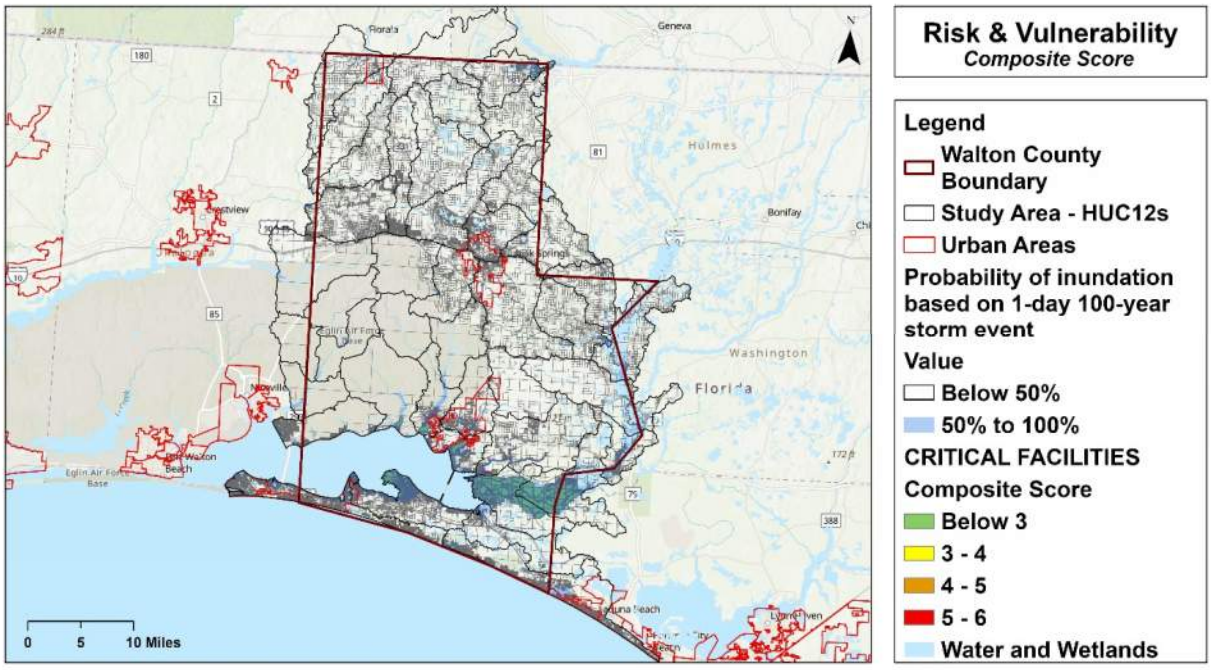

Figure 39. Walton County (mosaic) - Composite Score Risk map overlaid on the 1-day 100-year storm event probability of inundation. Processed by FAU.
Please note that due to the scale of the map, the composite score layer is not properly visible in this map.

Please note that the composite score results display outcomes exclusively for parcels within the flooding path area. Consequently, for parcels outside this flooding path, the composite results will be null. The composite score combines the flooding path area with the land use priority results to identify the most vulnerable areas deserving of priority.

2.4.2 Solutions

Chapter 5 of the Watershed Master Plan for Walton County describes a list of possible gray and green stormwater strategies to combat flooding that can be implemented as solutions for the county. The same solutions can also be applied at the HUC level, including HUC 031402030403. A summary of these flood mitigation strategies is listed in **Error! Reference source not found.**. For more detailed information, please see Chapter 5-5.3 (Solutions).

Table 10. List of possible gray and green stormwater strategies to combat flooding

Strategy Class	Implementation Strategy	Applications	Benefits	Cost	Barriers to Implementation
Green	Rainwater harvesting	Local, small scale, easily implemented in developed areas	Protects property, treats runoff	Under $5,000	Limited volume disposed of, so many are needed, maintenance
Gray	Pervious paving	Parking lots, patios, driveways, anything except paved roads due to traffic loading	Reduces roadway and parking lot flooding	$10-20/sf, requires bumpers and sub-base to maintain paver integrity	Must be maintained via vacuuming or the perviousness fades after 2-3 years
Green	Detention	Common for new development, but difficult to retrofit; limited to open areas	Removes water from streets, reduces flooding	$200K/ac	Land availability, maintenance of pond, discharge location Uses up land that could otherwise be developed
Gray	Exfiltration Trench	Any low-lying area where stormwater collects and the water table is more than 3 ft below the surface; densely developed areas where retention is not available, roadways	Excess water drains to aquifer, some treatment provided	$250/ft	Significant damage to roadways for installation, maintenance needed, clogging issues reduce benefits
Gray	Central sewer installation	All areas where there are septic tanks. Mostly a water quality issue	Public health benefit of reducing discharges to lawns, canals, and groundwater from septic tanks	$15,000 per household	Cost, assessments against property owners, property rights issues
Green	Flood prone property acquisition	Regional agency - could be any low-lying areas	Removes flood prone areas from risk	$2K-$100K/ac depending on whether it is already developed	Difficult to implement if occupied, issues with willing sellers, cost, lack of funds for acquisition

Strategy Class	Implementation Strategy	Applications	Benefits	Cost	Barriers to Implementation
Gray	Pump stations	Any low-lying area where stormwater collects, and there is a place to pump the excess stormwater to such as a canal; common for developed areas	Removes water from streets, reduces flooding	Start at $1.5 to 5 million each, number unclear without more study	NPDES permits, maintenance cost, land acquisition, discharge quality
Gray	Armored sewer systems	Any area where gravity sanitary sewers are installed	Keeps stormwater out of sanitary sewer system and reduces potential for disease spread from sewage overflows	$500/manhole	Limited expense beyond capital cost
Gray	Sea walls	Barrier islands and downtown coastal areas	Protects property	$1200/ft	Private property rights, neighbors
Policy	Changes in land use	Applicable universally	Achieves flood risk mitigation by adjusting permitted land use	Low but may incur private property rights conflicts and litigation	Private property rights conflicts and litigation
Gray	Roadway base protection	Low-lying areas, coastal communities	Protects roads and access routes	$1 million per lane-mile	Cost, adjacent properties become uninsurable
Policy	Enhanced elevation of buildings	Developers would implement this for new construction	Reduced flood risk	Varies	Potential issues with building structure or latticework, and existing homes that are not elevated

2.4.3 Impacted Adjustment Areas

In the evaluation of flood risk management strategies within the framework of the National Flood Insurance Program Community Rating System (CRS), the concept of impact adjustment plays a pivotal role in determining the extent to which CRS-credited activities or elements influence the vulnerability of a community's Special Flood Hazard Area (SFHA) and the structures located within it. It's important to note that while the usual results of impact adjustment are related to the SFHA area, in this specific analysis, it was used 1-day 100-year storm event inundation area performed by FAU instead.

In this context, the following table presents a breakdown of the impact adjustment calculations for a 1-day 100-year storm event inundation. The values are expressed in acres and depict the areas of interest as well as the deductions considered in the evaluation process.

The outcomes of these calculations provide valuable insights into the impact adjustment scenarios:

With ALL State Lands:

This scenario reflects the remaining inundation area after accounting for deductions A, B, and C. It represents the effect of CRS-credited activities without considering the influence of state lands in managing flood risks.

With NO State Lands:

In this case, the remaining inundation area is determined by considering all deductions, including state lands (both open space and not open space – see **Error! Reference source not found.**).

These calculations highlight the dynamic nature of impact adjustment within the CRS framework. By accurately gauging the influence of individual elements, the system ensures that credit allocations align closely with a community's efforts in flood risk mitigation.

Table 11. Impacted Adjustment Areas for HUC 031402030403. Processed by FAU.

AREAS	**ACRES**
HUC-12 Sub-watershed: 031402030403	20352.88
All of the 1-day 100-year storm event inundation	**97.47**
Subtract	
A. Bodies of Water in 1-day 100-year inundation > 10 acres	0.00
B. Federal Land in 1-day 100-year inundation > 10 acres	0.00
C. Reservation/Tribal Land in 1-day 100-year inundation > 10 acres	0
D. State Land in 1-day 100-year inundation > 10 acres that is open space	0.00
E. State Land in 1-day 100-year inundation > 10 acres that is NOT open space	0.00
The remainder is either:	
With ALL State Lands: All of the 1-day 100-year inundation minus (A+B+C) or	97.47
With NO State Lands: All of the 1-day 100-year inundation minus (A+B+C+D+E)	97.47

2.4.4 Repetitive Loss Property Map

A Repetitive Loss (RL) property is a building that has had two or more loss or damage due to a specific hazard, such as floods, hurricanes, or other natural disasters, over $1,000 each, paid by the National Flood Insurance Program (NFIP) within any ten-year period since 1978. There are more than 122,000 RL properties in the nationwide (FEMA, 2005).

These data are essential for assessing the vulnerability of certain areas to recurrent losses and for developing strategies to mitigate the risks. However, due to privacy concerns, the data cannot be openly shared with the public. For this reason, the data were converted into a hot spot analysis map. These maps, instead of identifying the specific location of the repetitive loss properties, highlight clusters of repetitive loss claims and areas where the probability of repetitive losses is higher than would be expected by random chance. In other words, it helps pinpoint locations that have a higher concentration of properties prone to repetitive losses. **Error! Reference source not found.** indicates the results from hot spot analysis in point data, showing aggregated counts, and raster data, showing the estimated probability of repetitive loss.

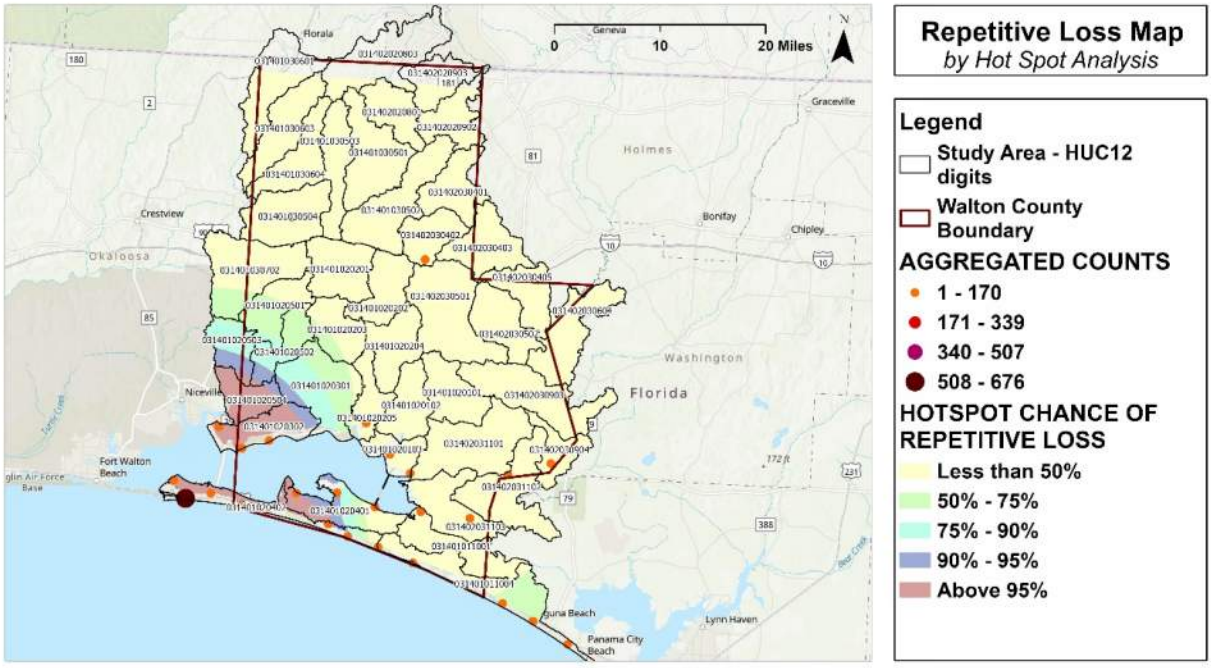

Figure 40. Repetitive Loss map for Walton County by Hot Spot Analysis. Processed by FAU.

2.4.5 Priority Projects

Although there are a good number of parcels falling within tiers classification 1 to 5 priority of land uses, only a few of them are within the flooding zone, once flooding in the area is relatively minor and not alarming. Consequently, when considering the composite score, it is notable that most of the results are null. There are only five exceptions within the basin: a utility parcel with score 4-5, and four mobile home parcels, all of them with scores below 3.

X.0 EXECUTIVE SUMMARY

The goal of the appendices to the watershed plan are to outline the issues associated with the individual HUC12s that contribute or impact the community's flood vulnerability and there for its flood protection efforts. Floodplain analysis includes developing a watershed model and identifying associated inundation polygons. It builds upon information generated from the watershed evaluation so that planning and management decisions can be formulated.

This appendix describes the issues and modeling associated with one of the HUC12s that affects Walton County. In developing the County-wide plan, this HUC 12 was analyzed so as to determine how it brings or removes floodwaters from the County. For the NFIP process the goal is to analyze all communities at the HUC12 level. From a community perspective the HUC12 is less useful to residents than a community-wide plan. Hence in all cases the HUC12 results were mosaicked into the community-wide plan. Details can be found in the HUC12 appendices, some of which were brought into the community plan.

To reduce redundancy, information of the plans, ordinances, policies and regulations were rolled up to the community-wide plan and will not be repeated in the appendices. Likewise, the community wide mapping was parced for HUC12 use.

1.0 WATERSHED CHARACTERIZATION

In this section, key aspects of the watershed are characterized. This is important for later being able to identify the most vulnerable areas and to mobilize resources to implement an action plan. Understanding the characteristics of the watershed involves gathering existing information and data sets from previous planning efforts. It is important to note that this step is iterative and ongoing as new data are generated and projects are implemented and monitored.

To assess the historical and current conditions of the study area, the following existing data sets that characterize the physical and natural features of the watershed were obtained for each HUC-12 subwatershed in the study area:

- Topographic data (LiDAR)
- Relevant waterway locations
- Groundwater levels
- Soils data
- Land uses including vacant land, wetlands, impervious, etc.
- Precipitation records
- Catchment delineations for flood routing

In addition, the FEMA flood maps must be obtained, and the storm of interest must be identified for screening purposes (1-day, 2-year, 5-year, and 100-year events as well as the 3-day 25-year storm event to achieve class 4 in the CRS Manual). In developed areas, many sources of data are already available – the key is putting the key datasets in a format that can queried for screening to identify the priority areas of the watershed. Table 6 is a summary of datasets available at cwr3.fau.edu that were used to construct this plan.

This watershed master plan is a drilldown of the larger Walton County TMDL region, which involves 42 HUC 12-digit sub-watersheds (**Error! Reference source not found.**). **Error! Reference source not found.** shows Walton County Drainage Network and the location of urban areas (cities and towns). In **Error! Reference source not found.**, the HUC-12 (031402030405) is highlighted among all the HUCs to help identifying its location. (Figure 3).

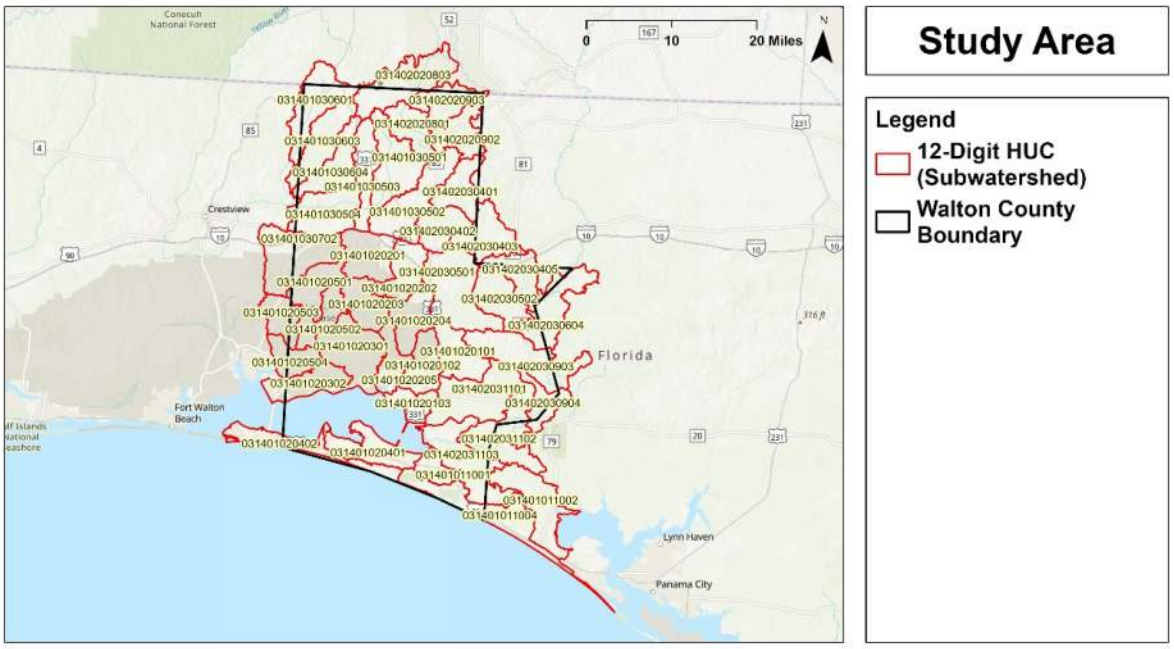

Figure 1. Walton County and all HUCs 12-digit subwatershed, processed by FAU.

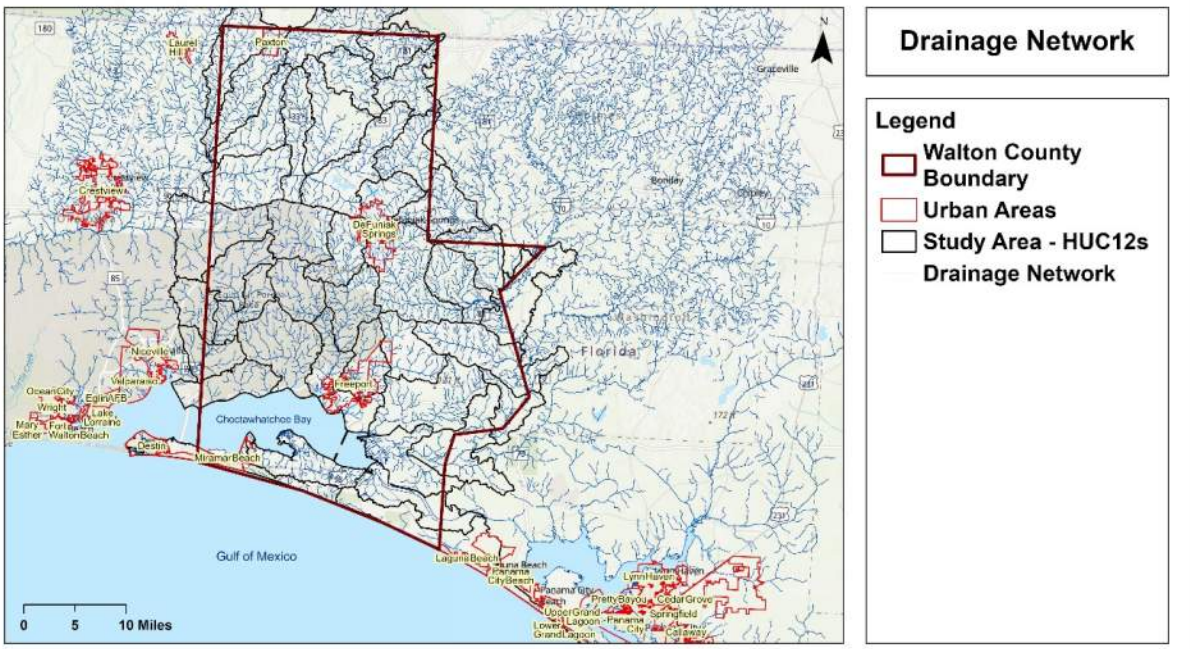

Figure 2. Walton County Drainage Network and urban areas (cities and towns), processed by FAU.

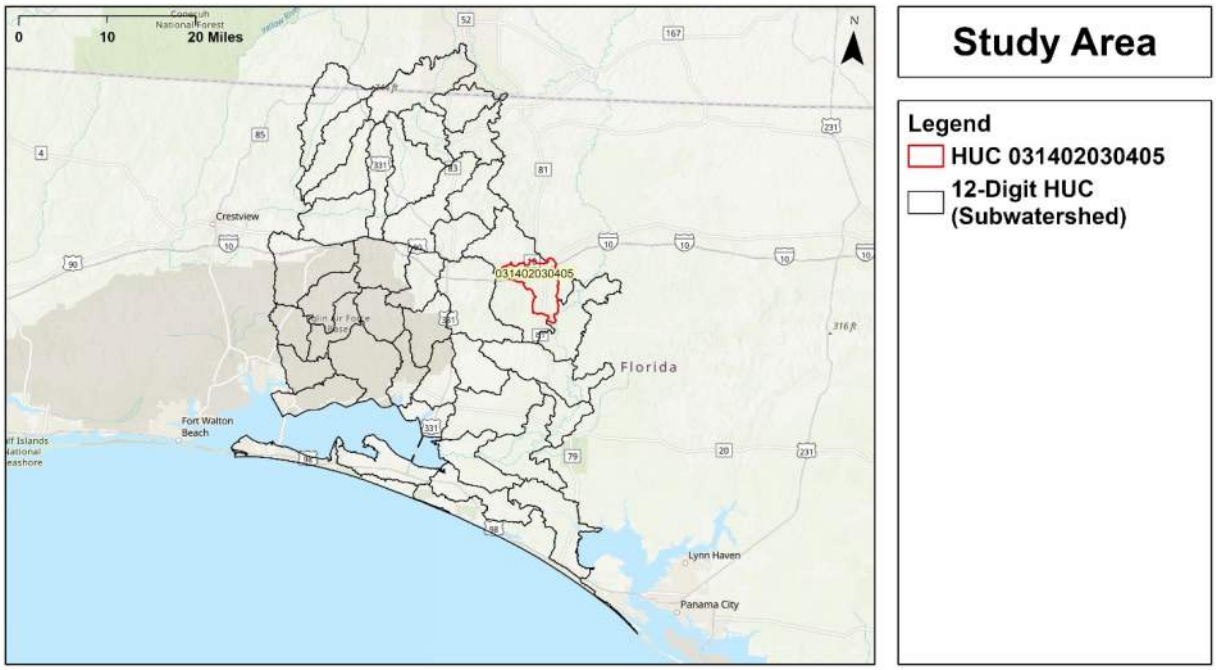

Figure 3. HUC 031402030405 sub-watershed location.

Located in the northwestern region of Florida, Walton County has 1,037.7 square miles of land and it is the 12th largest county in Florida by area, while also sits the highest point in the state, with a height of 345 feet in its northern end. With a population of 75,305 residents according to

the 2020 census and an estimate population in July of 2022 of 83,304, the county has experienced consistent growth within the past several years, driven by factors such as tourism, retirement migration, and regional population dynamics. The county was the residence for 55,043 people according to Census 2010, which leads to a percent change of 36.8% in 10 years, between 2010 and 2020, and a percentage change of 10.6% in two years, between 2020 and 2022 (United States Census Bureau).

The surge in population, particularly in the southern part of Walton County, has resulted in a corresponding expansion of infrastructure to cater to the growing needs. Essential facilities such as potable water systems, wastewater treatment plants, electrical utilities, roads, and schools have been developed to support this increasing population. However, the infrastructure expansion has brought about a significant change in the natural environment. Prior to the existing development , tropical cyclone impacts would be mitigated by natural barriers such as vegetated sand dunes, wetlands, and deserted beaches, which would absorb some of the destructive forces. Now, with the proliferation of costly infrastructure and residential dwellings in coastal areas, these storms pose a higher risk of potential damage. The very areas where development is occurring are becoming more vulnerable to the impact of severe storms, highlighting the importance of considering and implementing adequate measures to address potential storm damage in these coastal regions (Walton County Local Mitigation Strategy Plan, 2015).

Demographically, Walton County presents a heterogeneous age distribution, encompassing a blend of younger and elderly cohorts. The median age of approximately 44 years reflects the presence of both younger families and retirees seeking a serene and picturesque environment. Ethnically, the county' population is predominantly White with smaller yet notable populations of Hispanic/Latino, African American, and other racial/ ethnic groups.

Economically, the tourism sector stands as a dominant force in Walton County, constituting 23.4 percent of the workforce, according to Walton County Economic Development Alliance in 2011, due to its renowned beach destinations, such as Santa Rosa Beach, Miramar Beach, and the New Urbanist Communities of Seaside and Rosemary Beach. Following closely behind is the trade, transportation & utilities sector, accounting for 20.3 percent of employment, while construction stands at 10.0 percent in third place. Education, health care services, and public administration also play significant roles within the top five employment sectors, reflecting the diversified economic landscape of the county (Walton County Local Mitigation Strategy Plan, 2015).

The natural environment in Walton County contributes to its distinctive appeal to visitors and tourists. The county's coastal environment along the Gulf of Mexico showcases picturesque vistas, including white sand beaches, undulating dunes, and coastal dune lakes. These lakes, a rarity worldwide, provide unique ecological habitats. Walton County is also committed to environmental conservation, with designated protected areas comprising state parks, forests, and wildlife management zones. These preserved landscapes offer abundant opportunities for recreational activities, including hiking, fishing, and birdwatching.

The presence of wetlands and waterways further enhances the natural attributes of Walton County. Various rivers and creeks alongside Choctawhatchee Bay permeate the landscape, fostering diverse ecosystems and serving as crucial habitats for a wide range of wildlife species. This rich natural heritage encourages exploration and nurtures an appreciation for the environment.

DeFuniak Springs serves as the county seat and boasts a diverse economy. Anchored by sectors such as healthcare, education, retail, government services, and a thriving small business community, DeFuniak Springs offers a range of employment opportunities. Surrounded by the natural beauty of forests, lakes, and wetlands, the city enjoys the presence of Lake DeFuniak, a noteworthy natural resource. With a population of approximately 5,100 residents, DeFuniak Springs is a vibrant city featuring a mix of economic activities. The land area of DeFuniak Springs is approximately 12.6 square miles (32.7 square kilometers).

Freeport boasts a diverse demographic profile, and a developing economy. The city is situated along the shores of Choctawhatchee Bay, which provides opportunities for recreational opportunities and supports local ecosystems. Surrounded by lush forests and intersected by waterways, Freeport enjoys a rich environmental setting. In terms of economics, Freeport's economy is in a phase of growth and diversification, with sectors including healthcare, education, retail, and small businesses. The city is also strategically positioned for future economic expansion due to its proximity to major transportation corridors. Demographically, Freeport is a close-knit community with a population of approximately 2,600 residents, comprising a mix of permanent residents, retirees, and individuals seeking a suburban or rural lifestyle. The city reflects a diverse demographic composition, showcasing a variety of cultures, and backgrounds. Freeport occupies a land area of about 13.6 square miles (35.3 square kilometers)

Further along the coast, Miramar Beach stands as a coastal gem known for its tourism and hospitality industry. Luxury resorts, vacation rentals, gourmet restaurants, high-end retail shops, and entertainment venues thrive within this bustling city. Miramar Beach's main attraction lies in its stunning white sand beaches along the Gulf of Mexico, providing endless opportunities for beach activities and water sports. Its boundaries extend into neighboring Okaloosa County, attracting a blend of permanent residents, vacation homeowners, and rental property occupants. Miramar Beach, including its neighboring areas, covers an estimated land area of around 4.7 square miles (12.2 square kilometers).

Continuing along the Gulf Coast, we encounter Santa Rosa Beach. This coastal community is renowned for its vibrant tourism industry, offering a plethora of accommodations ranging from upscale resorts to charming vacation rentals. Its demography reflects a mix of permanent residents, seasonal visitors, and individuals seeking a coastal lifestyle, resulting in a diverse and dynamic community. Santa Rosa Beach spans a larger area compared to other cities in Walton County, with an estimated land area of approximately 31.2 square miles (80.8 square kilometers).

A summary of the existing CRS classifications for the communities in the study area is listed in **Error! Reference source not found.**. No cities in Walton County are listed in the FEMA Community Rating System Eligible Communities.

Table 1: Community Rating System for Walton County. Effective April 1, 2023.

Community #	**Community Name**	**CRS Class Rating**	**Premium Discount for SFHA**	**% Discount for Non- SFHA**	**Status**
120317	Walton County	6	20%	10	Cycle

(Source Data: FEMA)

Figures 12 and 13 is the county-wide report show the current and projected land use for the County. Based on the 2017 future land use for Walton County, only 7.07% of the land use in the county is urban and built up, and water/wetlands makes up 29.16% of the land use. The majority of land is upland forest, with 48.3%, as shown in **Error! Reference source not found.**..

Table 2. Land Use in Walton County (Prepared by FAU from future land use map) versus land use in the entire watershed

Level 1 Land Use-Land Cover Type	**Area (Acres)**	**Percentage of Total**
Agriculture	52958.94669	7.17%
Barren Land	9242.05986	1.25%
Rangeland	40326.66002	5.46%
Transportation, Communication, and Utilities	11815.69287	1.60%
Upland Forest	356796.0541	48.30%
Urban and Built-Up	52194.79061	7.07%
Water	61593.80508	8.34%
Wetlands	153759.9055	20.82%
Total	**738687.9147**	**100.00%**

(Source Data: (NWFWMD 2017)

Walton County has a history of flooding and has implemented various measures for flooding mitigation over the years (see section 1.12 for more details). The County has experienced flooding primarily due to heavy rainfall events and proximity to large water bodies such as the Gulf of Mexico, Choctawhatchee Bay, and numerous rivers and creeks. The topography of the region, with low-lying areas in the coastal areas and wetlands, also contributes to flood vulnerability. The proximity to the ocean (Gulf of Mexico) makes the county vulnerable to sea level rise. Over the years, Walton County has faced multiple flooding incidents, including:

- March 1997: Heavy rainfall led to significant flooding throughout the county, resulting in property damage and road closures.
- April 2009: Intense storms caused widespread flooding, damaging homes and infrastructure and resulting in the declaration of a state of emergency.
- April 2014: Heavy rainfall caused severe flooding, leading to the evacuation of some residents and the closure of roads.

Today, the goal of a stormwater management system in many communities is to keep the community as a place to live and do business while limiting risk from damage due to flooding. The short-term impacts from stormwater include flooding in low-lying areas and standing water in areas with limited soil storage capacity. Less common, but of increasing frequency, is the potential for extensive inundation of some areas, especially low-lying areas, during periods with high groundwater levels and groundwater impacted by sea level rise. As a result, there is a need to understand the economic impact of flooding events and to create cost-effective stormwater infrastructure and policy solutions to protect property. This means preserving as much property and economic activity as possible without disrupting current activity or expending funds on inappropriate projects with limited long-term or social value.

1.1 Surface Topography

Topography is a key parameter that influences many of the processes involved in flood risk assessment, and thus, up-to-date, high-resolution, high-accuracy elevation data are required. In order to meet the requirements for FEMA Risk Mapping, Assessment, and Planning (RiskMAP), 1-meter (2015 to present) and 1/9 arc-second (~ 3-meter) (2010 -2015) LiDAR DEMs were acquired. The 1 m × 1 m LiDAR tiles were kriged to create a topographic map of the study area (**Error! Reference source not found.**). This accuracy meets the 3DEP Quality Level 2 vertical root mean square error accuracy threshold of ±10 cm for FEMA (Arundel et al., 2015). The LiDAR used for this basin was 2016.

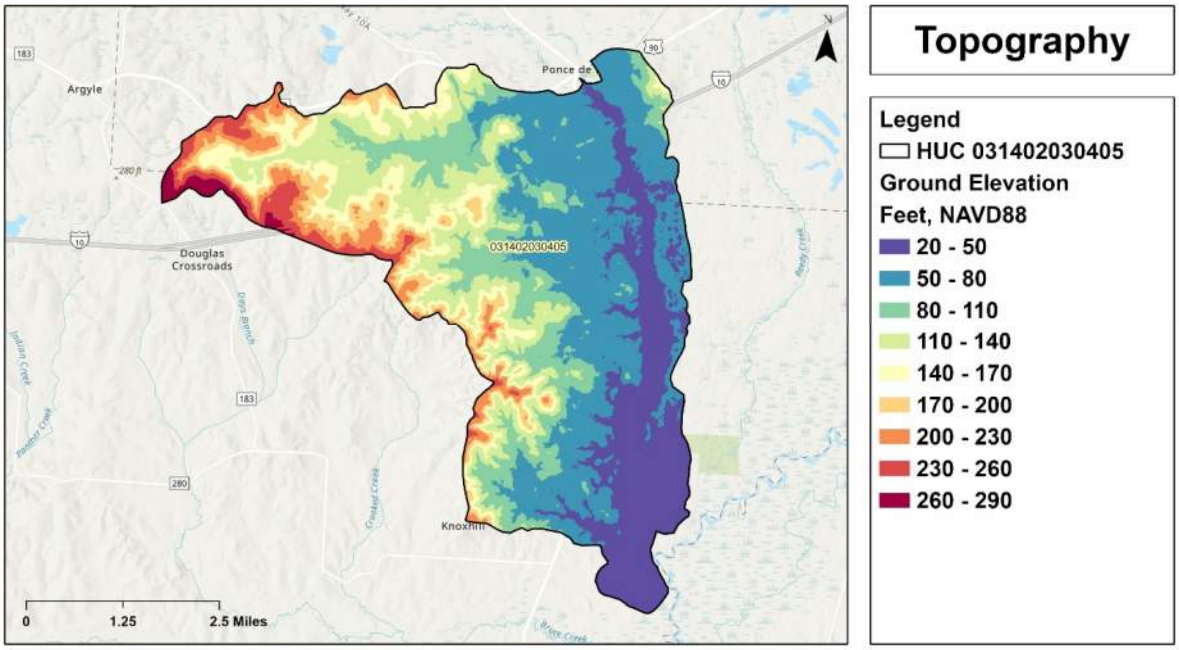

Figure 4. Topographic map of the HUC 031402030405 sub-watershed, processed by FAU.

1.1.1 Geomorphological Considerations

Walton County's coastal area is characterized by the presence of barrier islands, extensive sandy beaches, and coastal dune systems. These features are influenced by the dynamic processes of wave action, tidal currents, and wind-driven sediment transport. The shoreline is subject to natural changes, including erosion and accretion, which significantly shape the coastal geomorphology. Inland Walton County exhibits a mix of wetlands, forests, rolling hills, and rivers. These landforms are influenced by a combination of factors, including underlying geology, fluvial processes, and the region's hydrological regime.

Like many areas in Florida, Walton County is underlain by limestone formations. The specific composition and properties of these limestone formations in Walton County may vary. However, limestone is generally known for its porous nature, which allows for the absorption and storage of water. Underground aquifers within the limestone formations can hold significant volumes of freshwater, contributing to the region's water resources.

For context, the FIRM panel index of HUC 031402030405 sub-watershed is shown in **Error! Reference source not found.**.

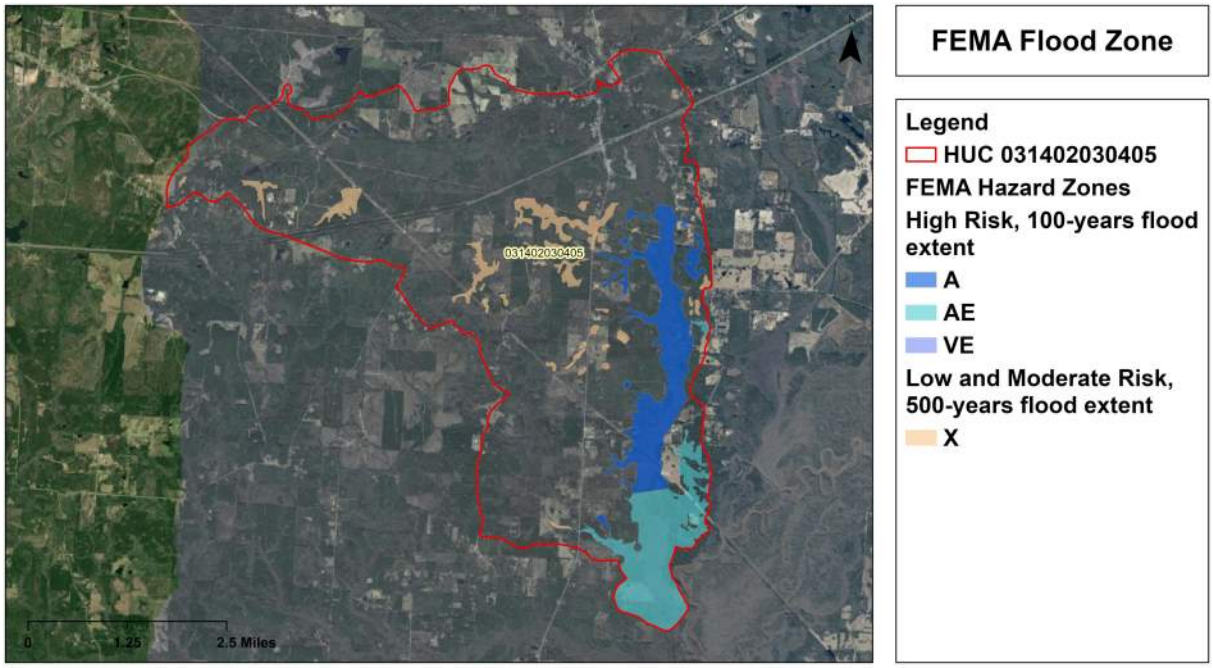

Figure 5. FEMA Flood Zone map (2020) for HUC 031402030405 sub-watershed, processed by FAU.

1.1.2 Waterway Features

In Walton County, Florida, the waterway features are primarily influenced by the presence of rivers, creeks, bayous, and the proximity to the Gulf of Mexico. To the south of Walton County lies the Gulf of Mexico. Sandy beaches, barrier islands, and the open waters of the Gulf itself characterize the coastline along the Gulf. The Gulf of Mexico influences the coastal processes, including wave action, tidal currents, and sediment transport along the shoreline. The combination between sea level rise and King tide would have detrimental consequences for the county costal area, including the sub-watershed 031402030405 as it will reach the area thought Choctawhatchee Bay.

Walton County is home to several rivers and creeks that meander through its landscape. These waterways provide drainage for the inland areas and contribute to the overall hydrological system. Examples of significant rivers in the county include the Choctawhatchee River and the Shoal River. In addition, Walton County features bayous and estuaries that connect inland water systems to the Gulf of Mexico.

Choctawhatchee Bay serves as a vital estuarine ecosystem, where freshwater from rivers and creeks mixes with the saltwater from the Gulf of Mexico, serving as a vital estuarine ecosystem. This unique brackish water environment supports a rich diversity of flora and fauna, including

various fish species, shellfish, migratory birds, and wetland vegetation, contributing to the overall biodiversity of the region. It also plays a significant role in the local economy of Walton County as it supports commercial and recreational fishing industries, providing livelihoods for local fishermen and contributing to the seafood industry, while also offering a range of recreational opportunities for residents and visitors alike, such as boating, kayaking, paddle boarding, and sailing. **Error! Reference source not found.** shows the bathymetry offshore.

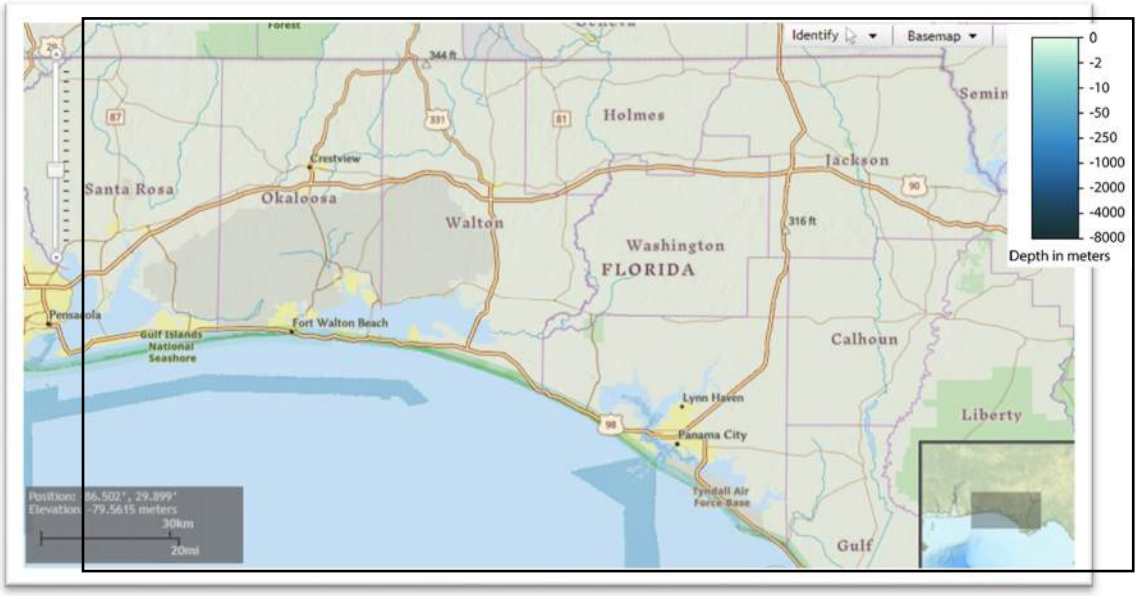

Figure 6. Bathymetry map of the shore of Walton County and surrounding counties of Florida Panhandle. Source: ncei.noaa.gov/maps/bathymetry/

Numerous tributaries exist throughout both the freshwater and estuarine portions of the watershed and can influence the overall hydrology of the area depending on rainfall and regional hydrological conditions. **Error! Reference source not found.** shows the location of all four surface water stations along with ground water stations (wells) and the drainage network of Walton County.

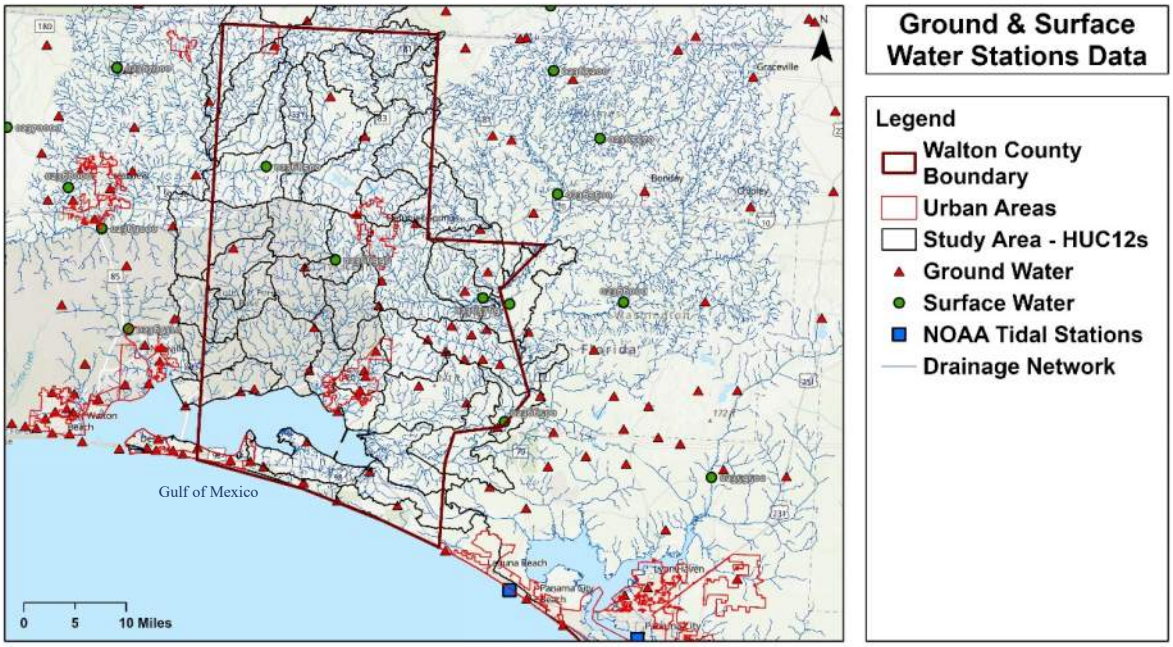

Figure 7. Ground & Surface Water Stations with drainage network for Walton County, processed by FAU.

1.1.3 Hydrologic Boundaries

The geographic area of the subject sub-watershed should be clearly defined to ensure that implementing the WMP will address all the major sources and causes of impairments and threats. Although there is no rigorous definition or delineation of this concept, one way to identify the geographic extent of the watershed master planning effort is to consult the United States Geological Survey (USGS) map of hydrologic units. A hydrologic unit is part of a watershed mapping classification system showing various areas of land that contribute surface water runoff to designated outlet points, such as lakes or stream segments. USGS designates drainage areas as sub-watersheds (including smaller drainages) numbered with 12-digit hydrologic unit codes (HUCs), nested within watersheds (10-digit HUCs). These are combined into larger drainage areas called subbasins (8 digits), basins (6 digits), and subregions (4 digits), which make up the large regional drainage basins (2 digits).

Region>>Subregion>>Basin>>Sub-basin>>Watershed>>Sub-watershed

The HUC 031402030405 has no major rivers and canals, but creeks and branches which include:

- Sandy Creek
- Camp Branch

- White Creek
- Hughes Ditch
- Oak Grove Branch
- Mill Creek

Given that stream flow data are critical for estimating flooding, **Error! Reference source not found.** shows the historical streamflow during June 2022 to July 2023 for USGS 02365769. However, as there are only four surface water station within Walton County, it was necessary to use the nearest station to the sub-watershed 031402030405, which is USGS 02365769 Bruce Creek at SH 81 NR Redbay, FL.

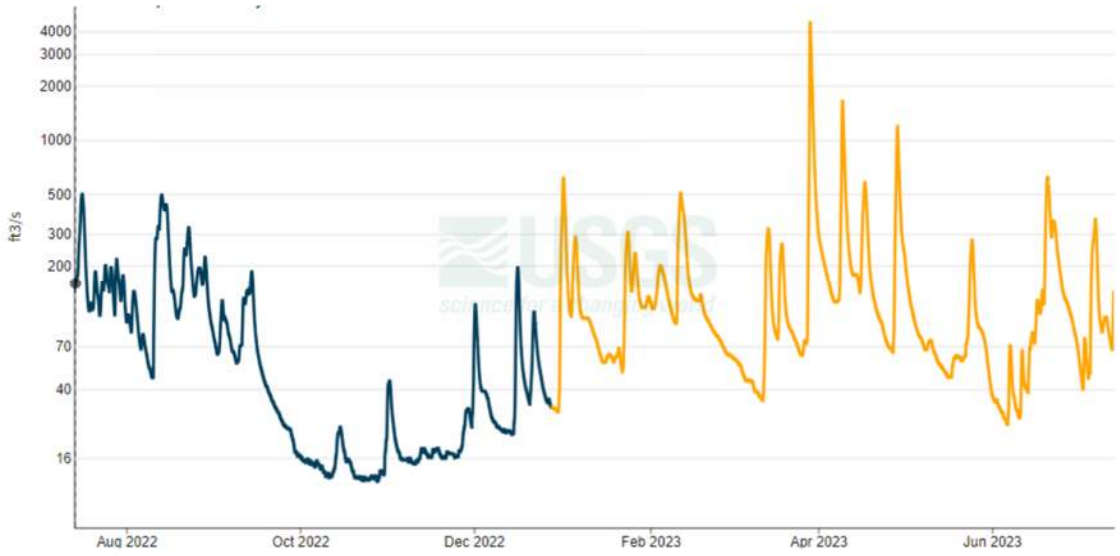

Figure 8. Average streamflow for Bruce Creek at SH 81 NR Redbay, FL (USGS 02365769 Surface-Water, June 2022 to July 2023).
Source: USGS Water Data Services (hhttps://waterdata.usgs.gov/monitoring-location/02365769/#parameterCode=00065&period=P7D).

1.2 Groundwater

In this region of Florida, there is a direct interaction between groundwater and surface water. In addition to low land elevations and topographic relief, the groundwater and surface water are controlled by the canals, rivers, and tides. Since there is a limited number of groundwater monitoring stations, the strong relationship between groundwater and surface water was leveraged to develop a 99th- percentile surface of the water table elevation for mapping purposes. To establish a common date for modeling, the recorded groundwater table elevations were sorted in ascending order to determine the 98th - 100th percentile date of occurrence in Excel®, following the procedure

detailed in Romah (2011). This procedure was automated for this effort using a python code to process the groundwater data more efficiently. Outliers and anomalous groundwater levels in the database are initially identified (e.g. catastrophic storm events) and replaced by region-specific mean values based on observations available from the nearest well. Missing date-specific data are estimated using simple temporal interpolation based on observations available in time. If a station (or monitoring well) data contains large amounts of missing data, it is not used in the generation of the groundwater surface.

In Walton County, the average annual rainfall is abundant, reaching 65 inches at DeFuniak Springs. This rainfall predominantly infiltrates the sand-and-gravel aquifer and eventually seeps into streams or the underlying artesian Floridan aquifer. The county's two major aquifers are the sand-and-gravel aquifer and the Floridan aquifer. While the sand-and-gravel aquifer provides water for rural domestic use and plays a crucial role in water storage and streamflow maintenance, it also serves as a recharge source for the Floridan aquifer. Water from the sand-and-gravel aquifer contains varying levels of dissolved solids, pH, and iron content. The Floridan aquifer, being the primary water supply source, underlies the entire county and yields around 500 to 1,000 gallons per minute from wells, except along the Gulf Coast where the permeability is lower. Recharged by leakage from the sand-and-gravel aquifer, the Floridan aquifer's movement is predominantly southward away from the potentiometric high in northwestern Walton County. It discharges through springs, seeps along the Choctawhatchee River, and by wells. In southern Alabama, the Floridan aquifer is directly recharged by rainfall when it is exposed or close to the land surface. (Bureau of Ecology, 1974).

Once a common time period is determined across the majority of shallow groundwater wells, canal data can be gathered for that common date (and two days prior, in the event the canals were deliberately lowered Data was obtained from the NWFWMD and processed by FAU at cwr3.fau.edu. Between stations, an ArcGIS tool permits a line to be drawn to replicate the canals and establish points in a gradient between stations. The same is true for the ocean, but it is a constant head boundary. The canals form boundary conditions for the screening tool on the edges of the basin and affect localized groundwater. The tide issue is resolved by using the common date for high tide.

Error! Reference source not found. shows the drainage network of HUC 031402030405 and points out the location of the ground water station in the surroundings. A groundwater-surface layer for the HUC 031402030405 sub-watershed was created using several datasets including water level data from USGS and NWFWMD and groundwater elevation contour maps. The datasets were used to generate a raster surface of the groundwater elevation (**Error! Reference source not found.**).

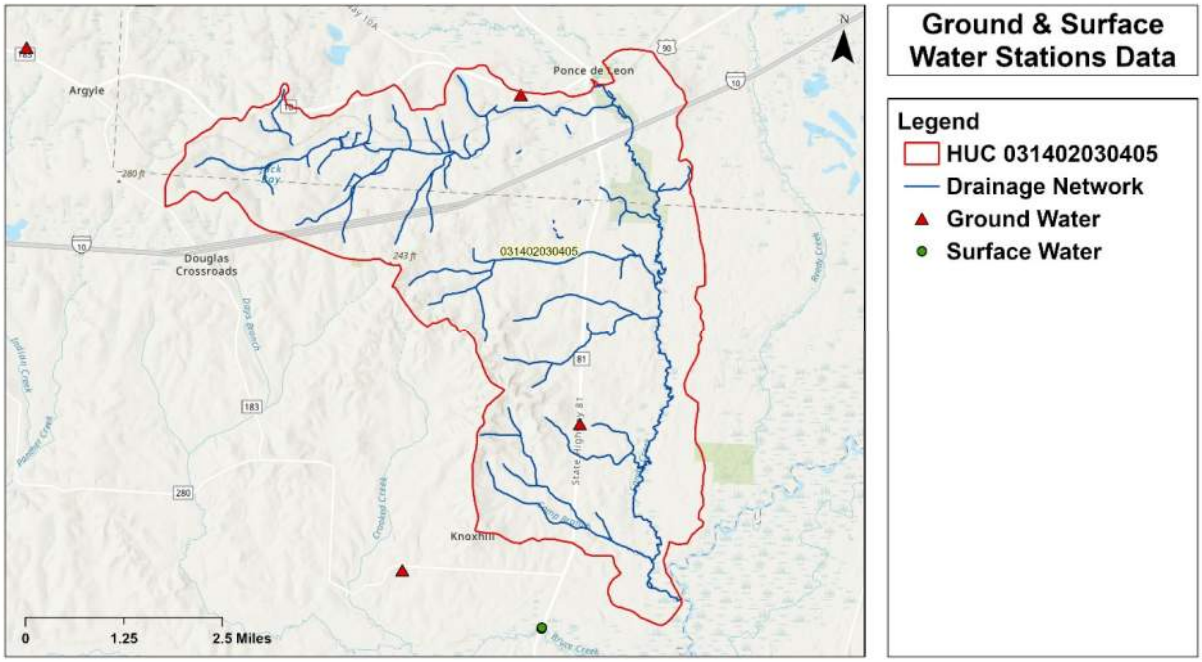

Figure 9. Ground and Surface Water Stations in the HUC 031402030405 sub-watershed, processed by FAU.

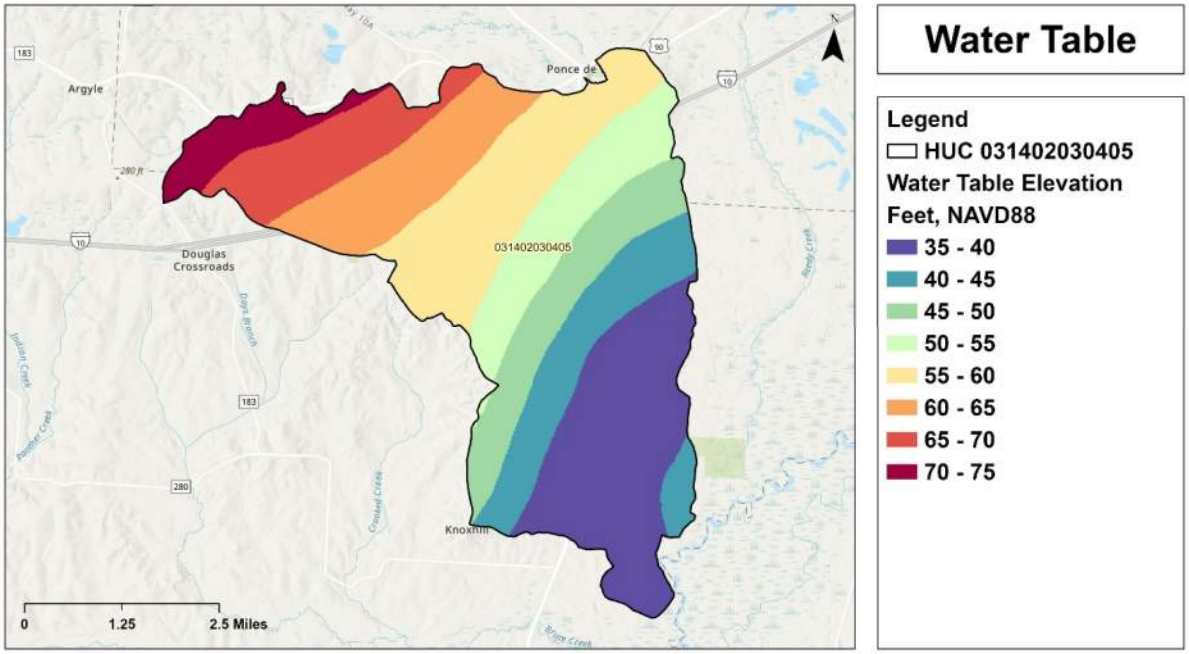

Figure 10. Elevation of the top of the surface groundwater layer for the HUC 031402030405 sub-watershed, created by multiple linear regression analysis – elevation NAVD88, processed by FAU.

1.3 Surface Water/Tides

Historically, surface water and tides have been an important factor in determining how much freshwater is delivered, how fast this water enters wetlands and estuaries, and the quality of that water. Evapotranspiration and rainfall do not coincide in the study area, which makes water supply planning difficult. **Error! Reference source not found.** shows the average precipitation over Walton County for every month of the year between 2011 and 2023.

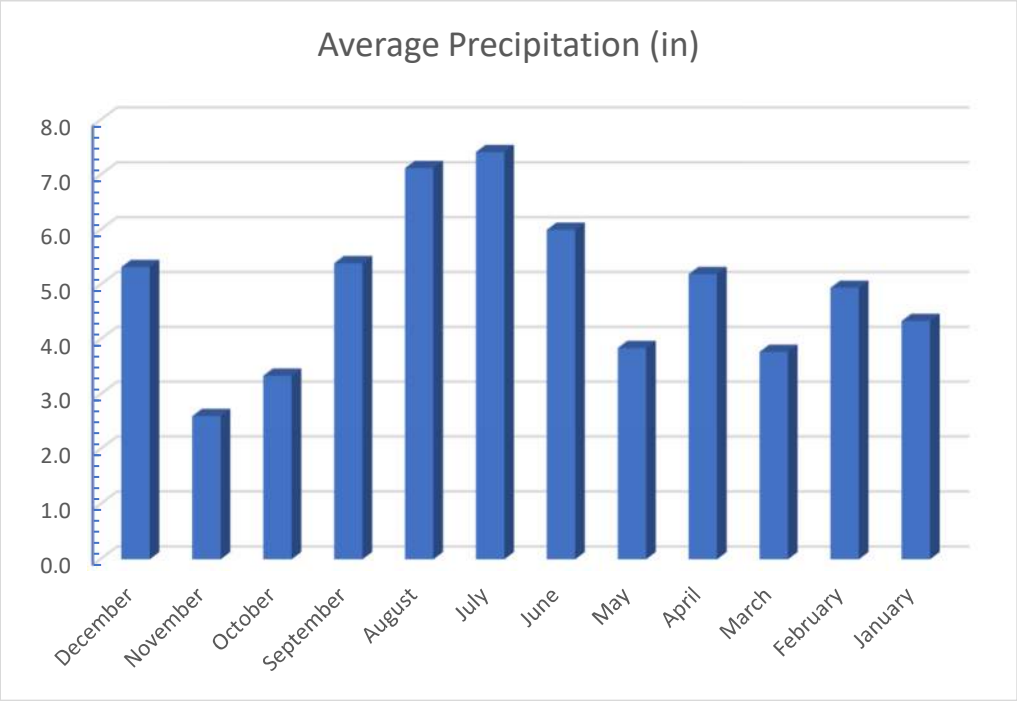

Figure 11. Monthly precipitation in Walton County, FL (2011-2023).
(Data Source: Florida Weather Data, available at https://data.usatoday.com/weather-data/walton-county/12131/1975-04-01/Table/)

While the topography (Section 1.1) and native soil (Section 1.4) create an environment that is highly permeable and capable of infiltrating significant percolation into the soil, changes in land use and land cover have resulted in water falling on impervious areas, where the water collects in pools or runs off rapidly, in direct contrast to the natural condition. This runoff flowing over impermeable regions can lead to larger scale flooding.

Tidal data can be gathered from NOAA tidal gages and other gages monitored by local governments. The location of tide gages is important to ensure they accurately depict tides, as opposed to inland waters. To set a boundary for the coastal areas, the high tide on the common date from 12/03/2018 to 12/10/2018 was selected. **Error! Reference source not found.** shows

the two closest tide stations to Walton County. Since there are no NOAA tide station in Walton County, the Panama City Beach station (8729210) was used.

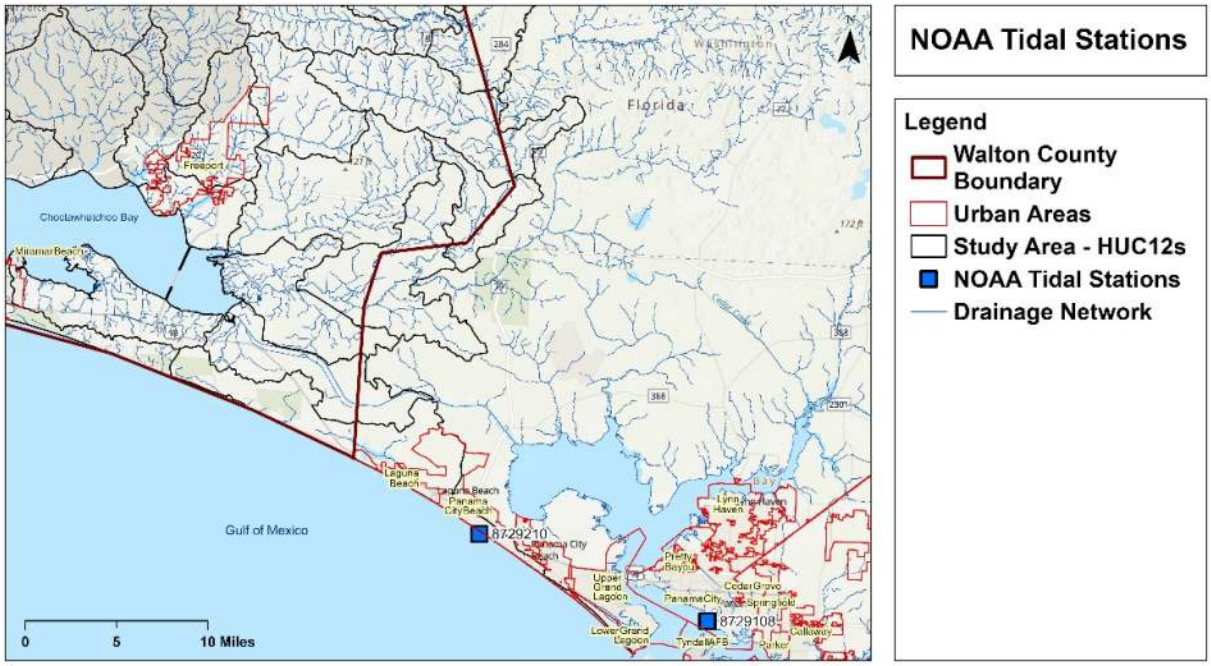

Figure 12. Locations of Florida tidal stations maintained by NOAA near to Walton County, processed by FAU.

1.4 Soils

Soil can store water if there is adequate distance between the topographic surface and the groundwater, and the soil types are capable of absorbing the water. Soil storage capacity is the volume of soil pores in the unsaturated zone that is available to store infiltrated stormwater (Gregory et al., 1998). Throughout Florida, it is common to have large volume storm events that fill the voids in the unsaturated zone as shown in **Error! Reference source not found.**.

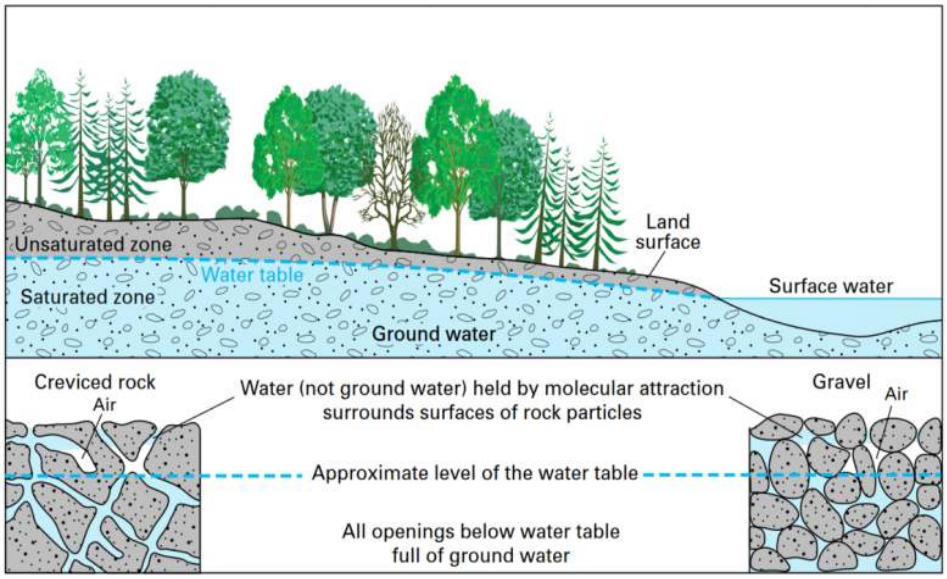

Figure 13. Zones where underground water exists.
Source: USGS, 2020.

The unsaturated zone is the portion of the subsurface above the water table that contains soil/rock and air and water in its pores as shown in **Error! Reference source not found.**. This zone affects the rate at which the aquifer is recharged by controlling water movement from the surface of the land downward towards the aquifer. During rain events, the soil voids fill up quickly resulting in the water table rising to the surface, and the surplus rainfall becomes runoff.

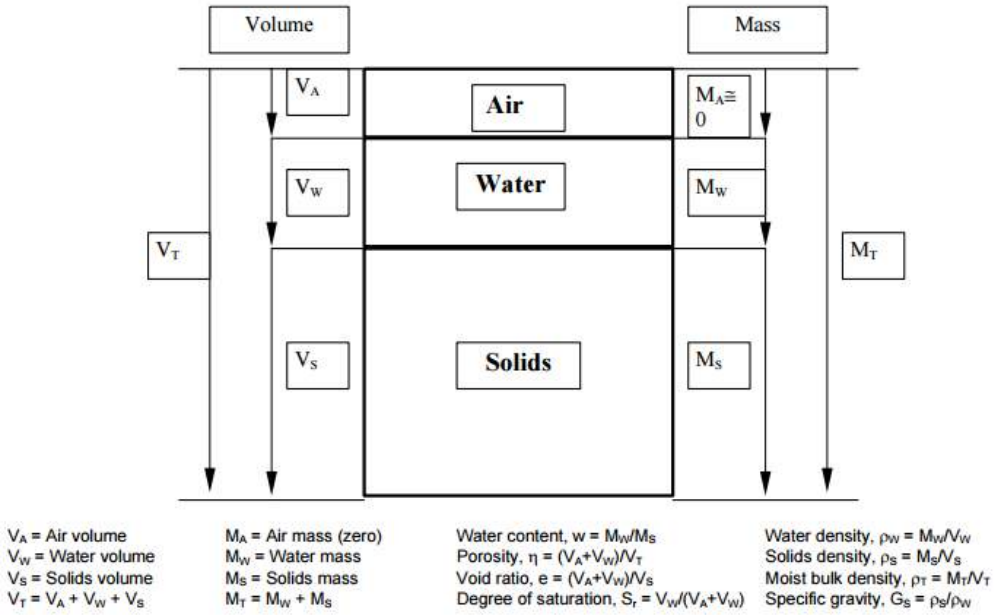

Figure 14. Saturated zone soil phase diagram and definitions.
Source: Gregory et al., 1998.

Soil data is available from the United States Department of Agriculture (USDA) or other agencies in the form of maps that can be incorporated as a GIS layer. The Gridded SSURGO (gSSURGO) dataset from USDA is chosen. This dataset is similar to the standard product from USDA Natural Resources Conservation Service (NRCS) Soil Survey Geographic (SSURGO) database, but is in the Environmental Systems Research Institute, Inc. (ESRI®) file geodatabase format. A file geodatabase allows for statewide or even Conterminous United States (CONUS) tiling of data. The gSSURGO dataset contains all of the original soil attribute tables in SSURGO. All spatial data are stored within the geodatabase instead of externally as separate shape files. Both SSURGO and gSSURGO are considered products of the National Cooperative Soil Survey (NCSS). **Error! Reference source not found.** shows the unsaturated zone found by the difference between the groundwater elevation layer and surface topography.

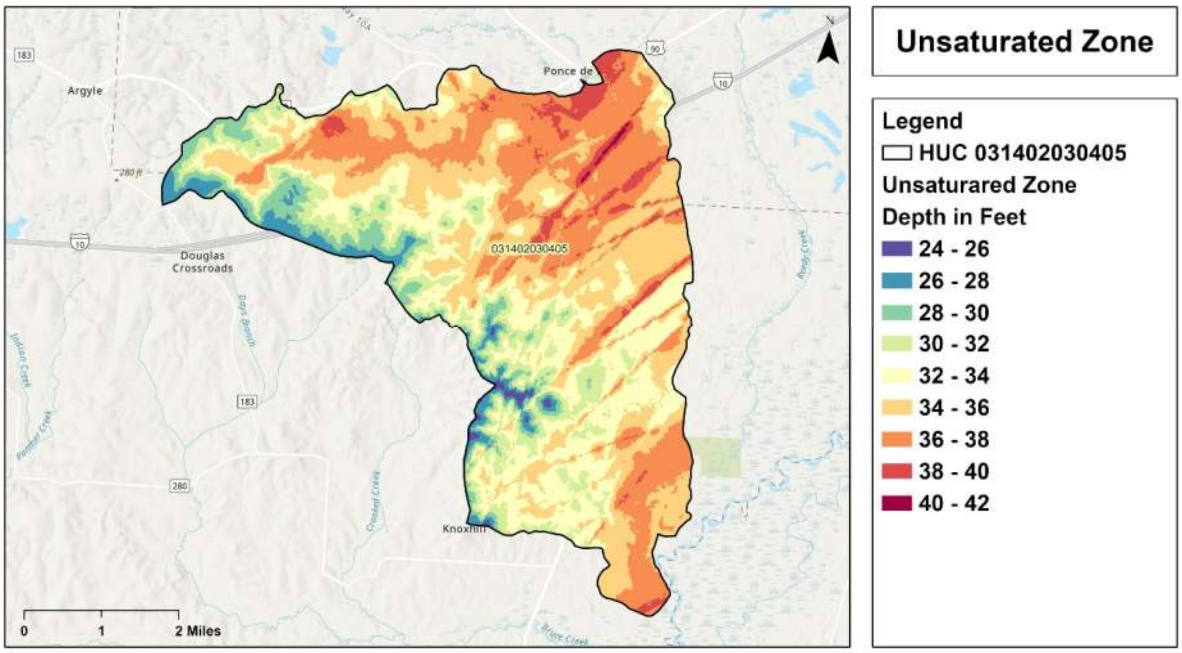

Figure 15. Unsaturated zone map for HUC 031402030405, processed by FAU.

The available water storage from USDA derived for the soil layer (0-150 cm or 0-5 ft) statewide is shown in **Error! Reference source not found.**, which covers most of Florida with a spatial resolution of 10 m. The unit is in cm. As a result of applying this layer to the study area (**Error! Reference source not found.**), the estimated soil storage capacity can be illustrated. A significant portion of the basin demonstrates a moderately favorable soil storage capacity, falling within the range of 30 to 40 feet of remaining capacity.

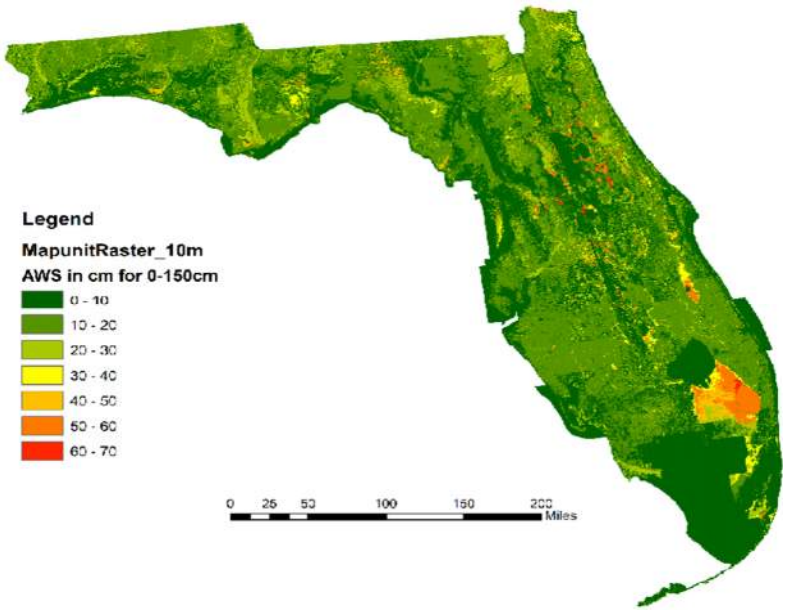

Figure 16. Available water storage derived from the gSSURGO soil database for all of Florida, as processed by FAU.

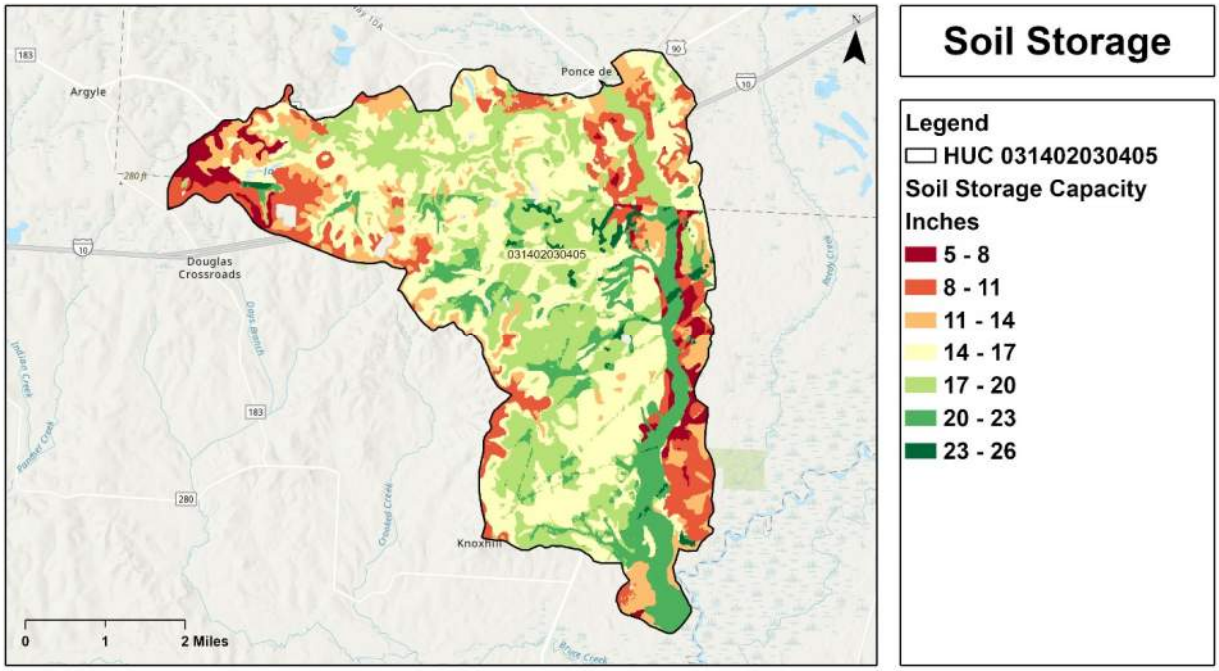

Figure 17. Water storage capacity of soil for the HUC 031402030405, processed by FAU.

Lastly, **Error! Reference source not found.** shows the water holding capacity for the basin, which refers to the capacity of a particular soil texture to retain water against the force of gravity.

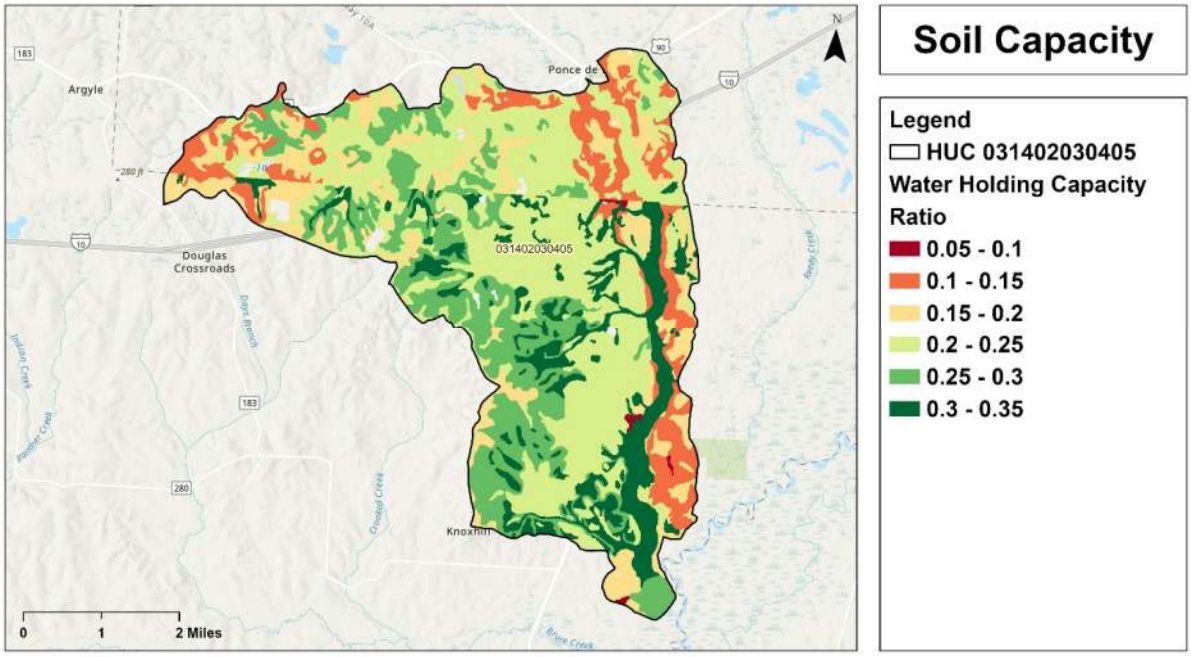

Figure 18. Water Holding Capacity (ratio) for the HUC 031402030405, processed by FAU.

1.5 Land Cover

The USGS produces the NLCD of nationwide data on land cover at a 30-m resolution with a 16-class legend based on a modified Anderson Level II classification system. NLCD is coordinated through the 10-member Multi-Resolution Land Characteristics Consortium (MRLC) to provide digital land cover information nationwide. For the conterminous United States, NLCD 2016 contains 28 different land cover products characterizing land cover and land cover change across 7 epochs from 2001-2016, urban imperviousness and urban imperviousness change across 4 epochs from 2001-2016, tree canopy and tree canopy change across 2 epochs from 2011-2016 and western U.S. shrub and grassland areas for 2016 (**Error! Reference source not found.**).

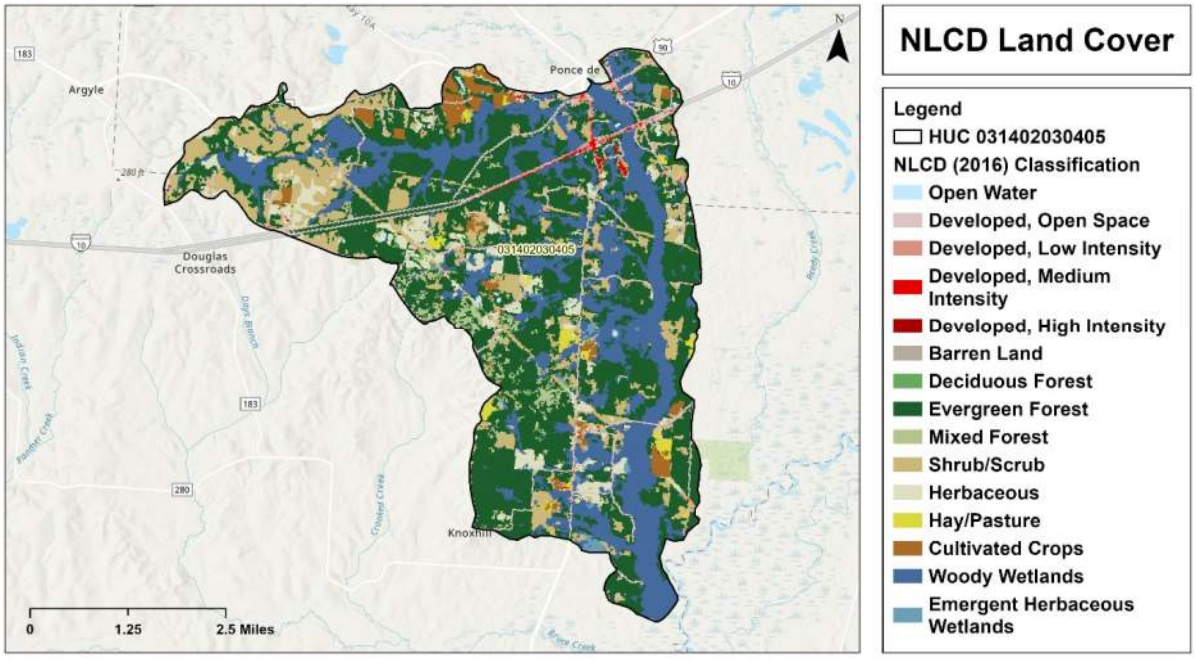

Figure 19. Land use in the HUC (from the 2023 Florida Geographic Data Library (FGDL) database), processed by FAU.

The dataset is derived from the Florida Land Use Cover Classification System (FLUCCS), which is digitized by photo-interpretation on county-based aerial photography with varying resolution in the range of 4 in - 2 ft pixel. The NLCD2016 has a 30-meter resolution derived from Landsat imagery. Hence, the NLCD maps appear much coarser and pixelated compared to the 2023 Florida Geographic Data Library (FGDL) (https://fgdl.org/fgdlmap/) maps. A view of the latter is provided in **Error! Reference source not found.**. The future land use maps need to be used for the final land cover, as adjusted for future stormwater improvements set by regulatory standards.

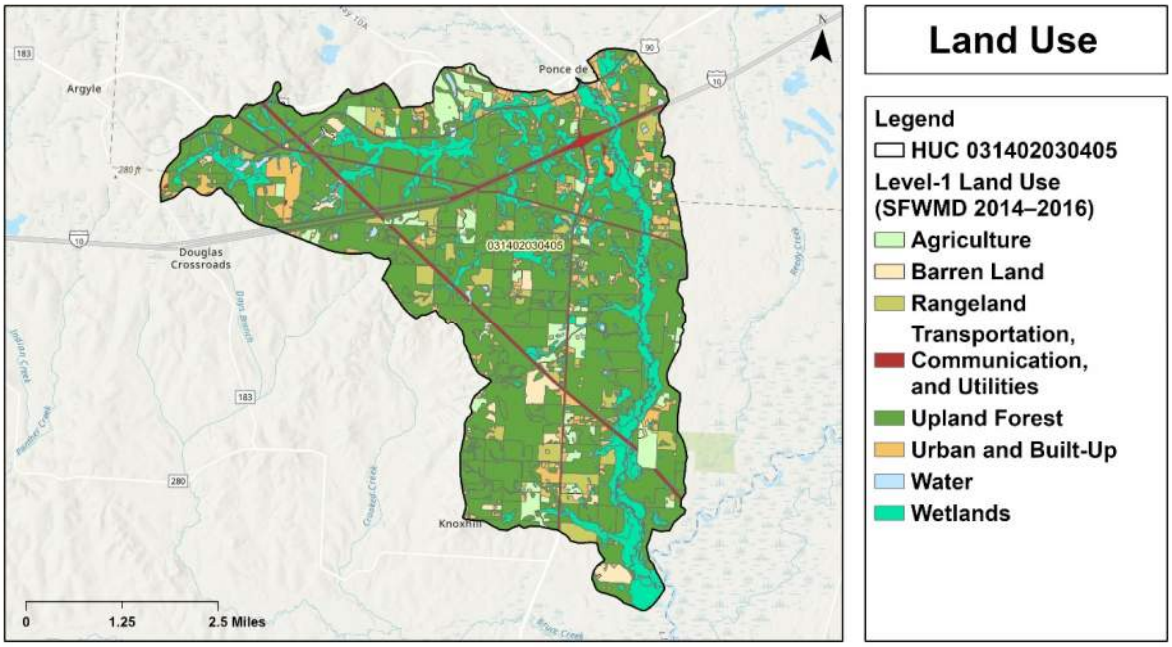

Figure 20. Land use in the HUC 031402030405 (from the 2023 Florida Geographic Data Library (FGDL) database)), processed by FAU.

In the HUC 031402030405 sub-watershed, the predominant land cover is upland forest, accounting for 51.06% of the area. Wetlands comes in second at 12.47%, followed by Transportation, Communication, and Utilities at 12.02%, and water at 11.42%. Developed land constitutes a minor portion, with only 3.87% categorized as urban and built-up, as shown in **Error! Reference source not found.**. **Error! Reference source not found.** shows the roughness of the surface.

Table 3. Land use for HUC 031402030405 subwatershed.

Level 1 Land Use Land Cover Type	**Area (Acres)**	**Percentage of Total**
Agriculture	1056.38	3.98%
Barren Land	326.07	1.23%
Rangeland	1054.53	3.97%
Transportation, Communication, and Utilities	3193.51	12.02%
Upland Forest	13567.97	51.06%
Urban and Built-Up	1029.02	3.87%
Water	3034.34	11.42%
Wetlands	3313.24	12.47%
Grand Total:	**26575.06**	**100.00%**

(Source Data: 2023 Florida Geographic Data Library (FGDL) database))

Table 4. Roughness and CN Values for Each Land Use Code

DOR Code	Use	Impervious %	Roughness
0	Vacant	0	0.4
1	Single Family	29	0.25
2	Mobile homes	21	0.05
4	Condos	60	0.05
7	Vacant –to be developed	0	0.4
8	Multifamily	60	0.05
TH 101	Townhomes	91	0.025
94	Road Right-of-Ways	50	0.08
	Open water	100	n/a
All others	Commercial, etc.	50	0.07

1.6 Precipitation

Rainfall used in the screening tool is based on the SFWMD 3-day 25-year storm, but can be modified for any rainfall event using the accumulated rainfall table obtained from NOAA Atlas 14 Point Precipitation Frequency Estimates (https://hdsc.nws.noaa.gov/hdsc/pfds/pfds_map_cont.html). **Error! Reference source not found.** shows the 3-day 25-year rainfall map based on the NOAA Atlas 14 dataset for the whole state. **Error! Reference source not found.** to **Error! Reference source not found.** rainfall 1-day 100-year, 1-day 10-year, and 1-day 5-year storm event scenarios, in inches.

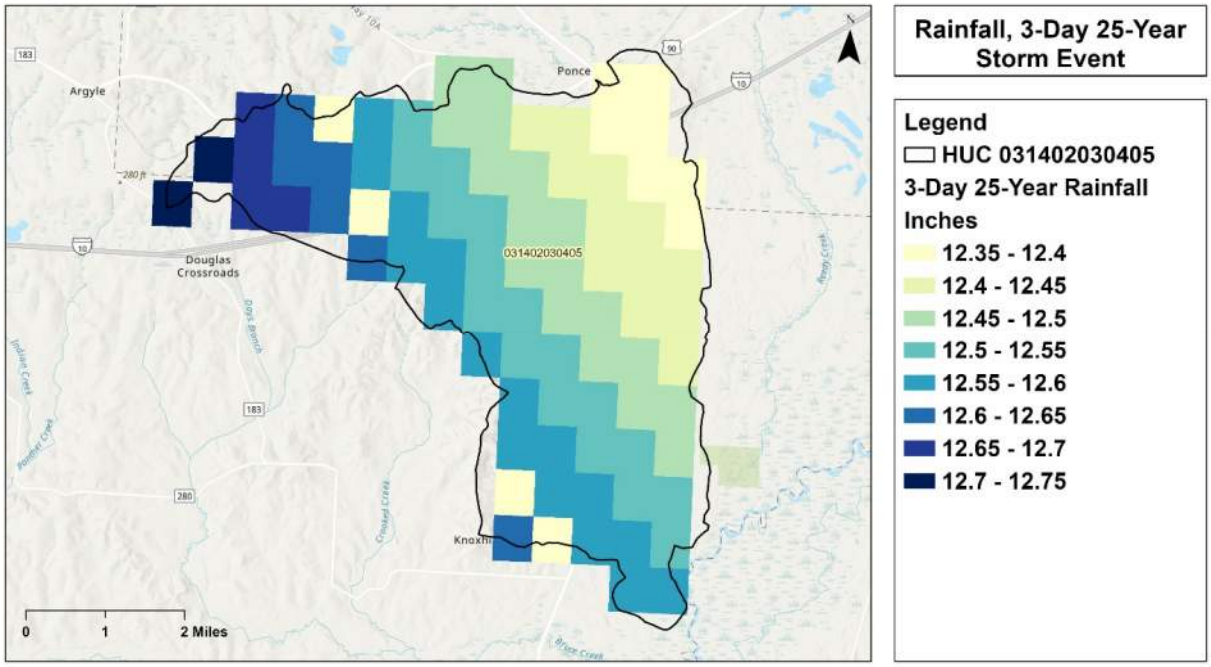

Figure 21. Rainfall distribution map across HUC 031402030405 sub-watershed, for 3-day 25-year storm event, processed by FAU.

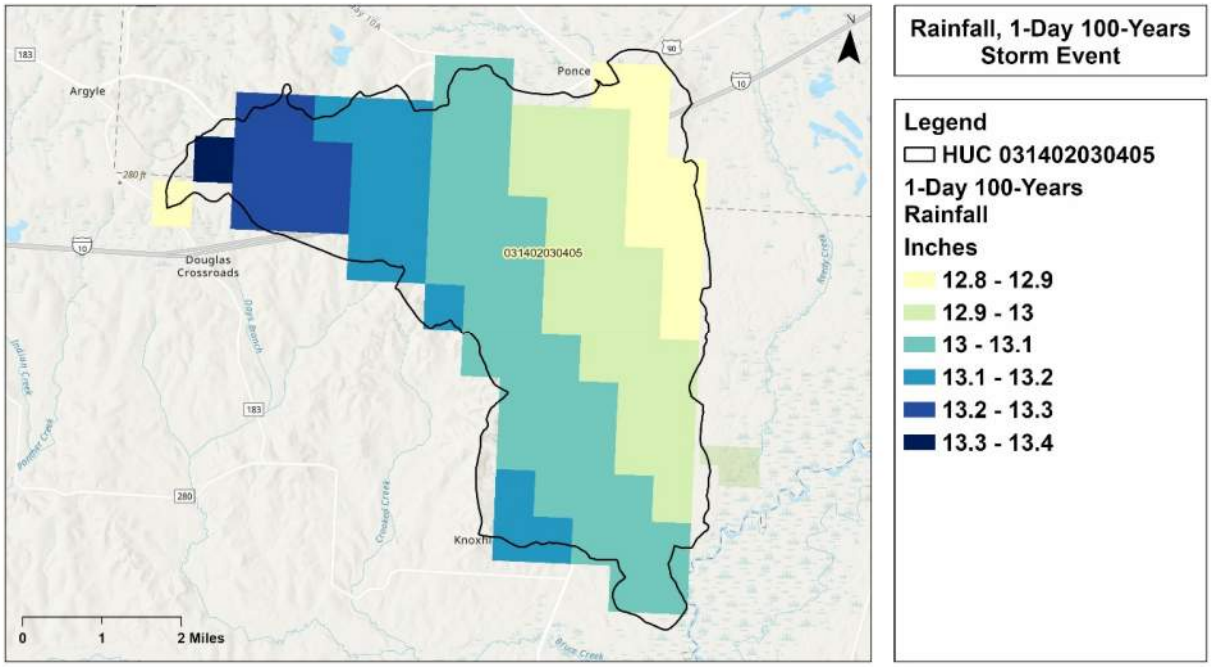

Figure 22. Rainfall distribution map across HUC 031402030405 sub-watershed, for 1-day 100-year storm event, processed by FAU.

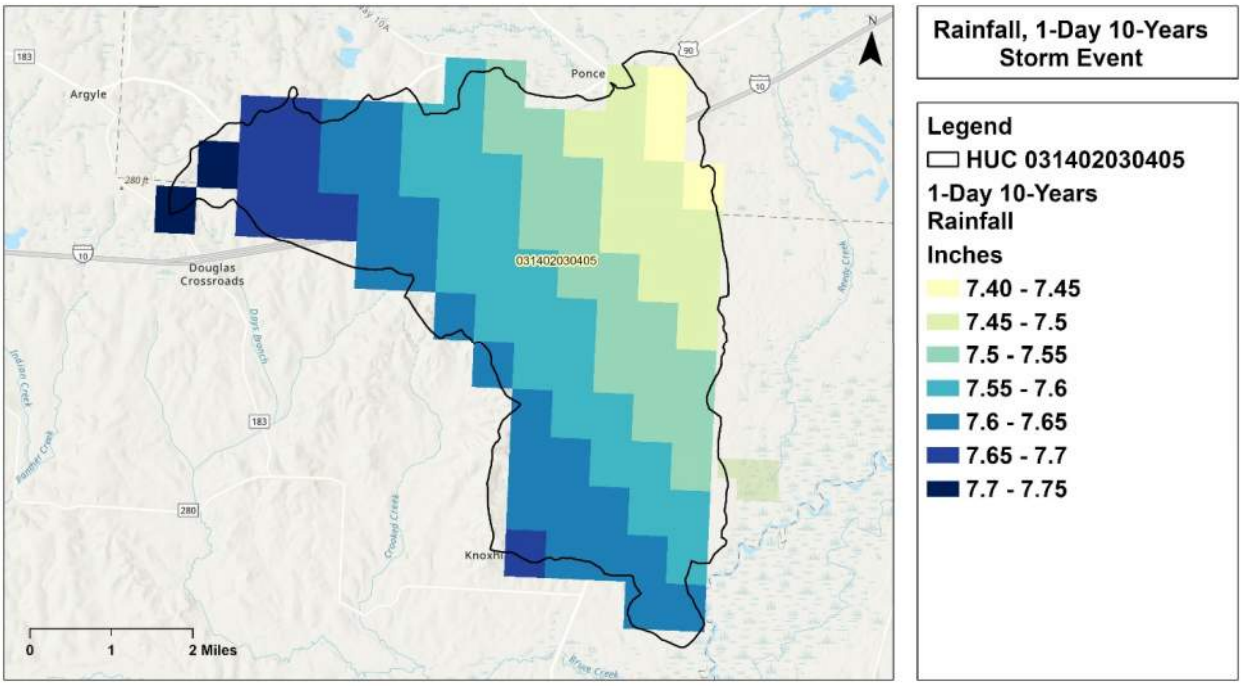

Figure 23. Rainfall distribution map across HUC 031402030405 sub-watershed, for 1-day 10-year storm event, processed by FAU.

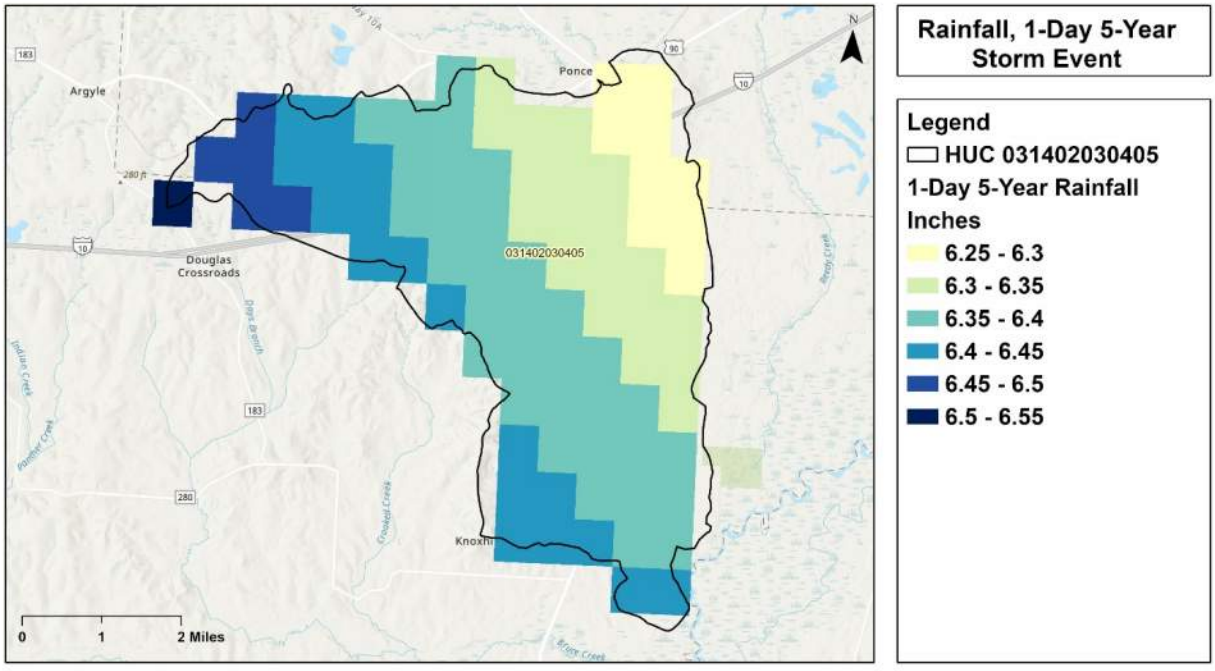

Figure 24. Rainfall distribution map across HUC 031402030405 sub-watershed, for 1-day 5-year storm event, processed by FAU.

1.7 Open Space

Open space is defined as areas that are exempted from development. Generally, this means one or more of the following qualifiers exist:

1. Land that is valuable for recreation, forestry, fishing, or conservation of wildlife or natural resources
2. Land that is a prime natural feature of the state's landscape, such as a shoreline or ridgeline
3. Land that is habitat for native plant or animal species listed as threatened, endangered, or of special concern
4. Land that is a relatively undisturbed example of an uncommon native ecological community
5. Land that is important for enhancing and conserving the water quality of lakes, rivers, and coastal water
6. Land that is valuable for preserving local agricultural heritage
7. Proximity to urban areas or areas with open space deficiencies and underserved populations
8. Vulnerability of land to development
9. Stewardship needs and management constraints
10. Preservation of forest land and water bodies that naturally absorb significant amounts of carbon dioxide

Permanent protection of sensitive areas can provide critical water quality protection and can be achieved through partnerships with landowners, municipalities, land trusts and state agencies. There is limited land in the study area that has been protected via acquisition by federal, state or local agencies, has conservation easements or is designated as wetlands or areas of critical concern. Agricultural land and other land cover will come from the land cover map (in Section 1.5). Added to this will be the water bodies discussed in Section 1.9, which serve a related condition to open space.

1.8 Impervious Areas

Impervious areas do not permit the infiltration of rainfall to groundwater, and because the water cannot infiltrate, it runs off faster. Faster runoff means that flows to water bodies and storm sewers occur faster and with higher peaks. The result is a disruption of the natural and potentially the planned hydrology. Impervious areas include pavement, buildings, and other areas that reduce runoff capacity. In other words, developed areas have much higher imperviousness than open spaces that are natural or agricultural.

The NLCD provides nationwide data on land cover and land cover change at a 30-m resolution with a 16-class legend based on a modified Anderson Level II classification system. Systematically aligned over time, the database offers the ability to understand both current and historical land cover and land cover change to enable assessment of trends. Using the NLCD 2016 dataset, a layer was created by using only three categories out of the 13 to identify impervious areas such as primary roads in urban areas, secondary roads in urban areas, and tertiary roads in urban areas. The new layer was then converted to match the 3-meter spatial resolution from the DEM and the standard State Plane Coordinate system. **Error! Reference source not found.** shows the impervious areas derived from the NLCD 2016 as updated by the future land use map.

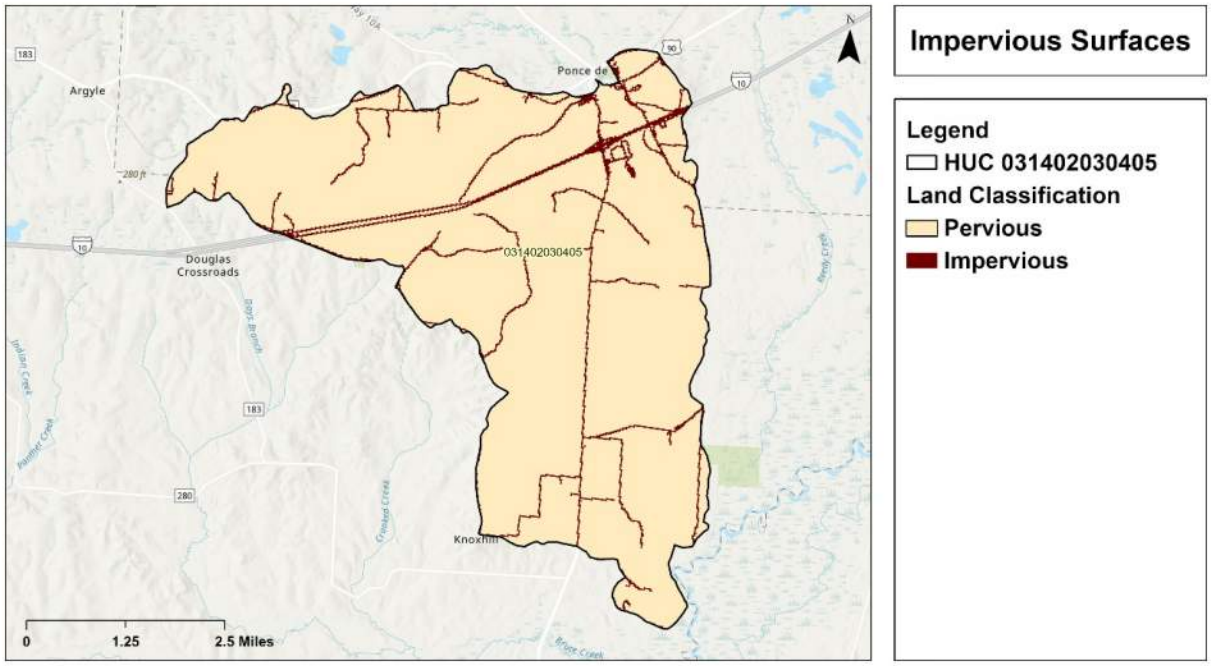

Figure 25. Impervious area map for the HUC 031402030405 sub-watershed, processed by FAU.

1.9 Water bodies

Water bodies were defined in the statewide land use land cover dataset to set soil water holding capacity to zero in model simulations (**Error! Reference source not found.**). Note that tiny water bodies may be missing from the maps. Soils were discussed previously in Section 1.4.

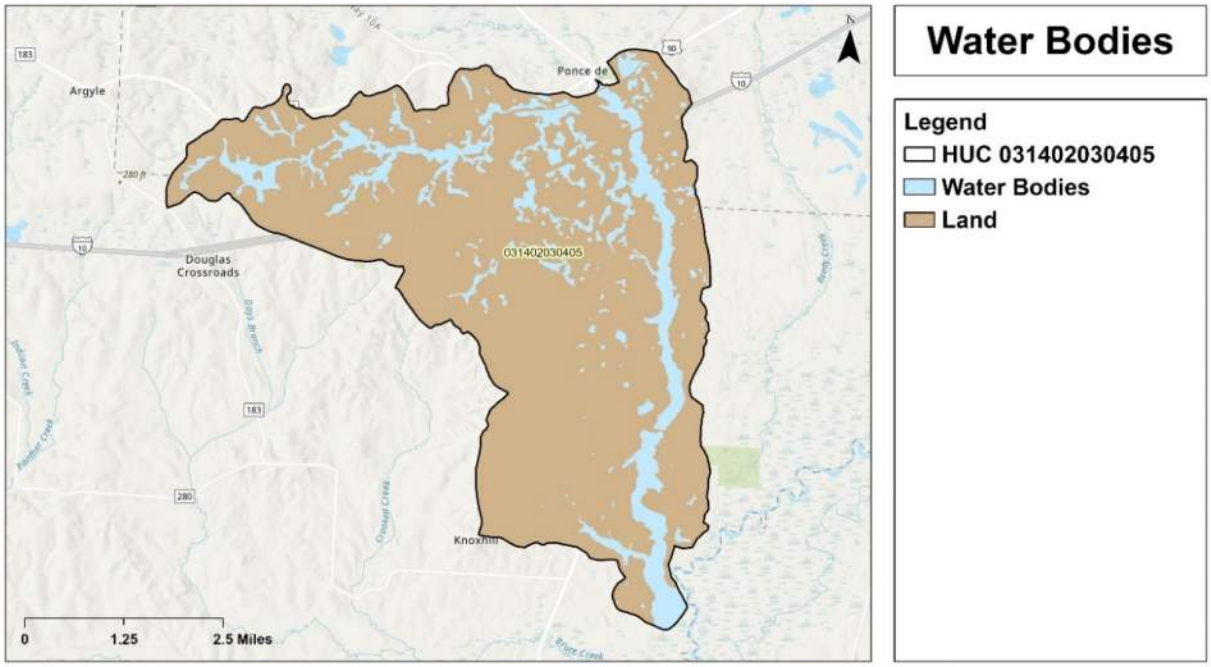

Figure 26. Water bodies map for the HUC 031402030405 sub-watershed, processed by FAU.

1.10. Natural Resources

Understanding the study area's natural resources is critical to identifying potential sources of water quality degradation and areas to designate for conservation, protection, and restoration. One possible goal of watershed master planning is to protect terrestrial wildlife, aquatic habitat, and buffer zones. USGS maintains important sources of information on physical and geographical features as well as soil and mineral resources, surface and ground water resources, topographic maps, and water quality monitoring data. The USDA's Natural Resources Inventory (NRI) (www.nrcs.usda.gov/technical/NRI) is a survey of information on natural resources on non-federal land in the United States that captures data on land cover and land use, soil erosion, prime farmland soils, wetlands, habitat diversity, erosion, conservation practices, and related items. Since 2001, the NRI has been updated continually with annual releases of NRI data from all 50 states. The information provided can be used for addressing agricultural and environmental issues down to the county or cataloging unit level. Therefore, this data can be used to determine erosion and site-specific soil characteristics for certain land uses such as croplands, pasturelands, forestlands, etc., but the data is typically provided as inventories, not GIS layers.

1.11 Demographics

Demographics data is important for determining several key indicators for watershed master planning such as the ability to pay for improvements, social justice issues, land acquisition costs, property/land use, and communication strategies. The US Census has databases at the census tract level. Based on the census data for the study area, **Error! Reference source not found.** outlines population and racial composition demographics.

Table 5. Demographics and Housing Characteristics of Cities and Towns in Walton County.

Demographic Parameter	**Miramar Beach**	**Freeport**	**DeFuniak Springs, City**	**Paxton**	**Rosemary Beach**	**Santa Rosa Beach***	**Walton County**

1.12 Stormwater Infrastructure Inventory

Local community stormwater systems consist of drainage ditches, storm sewers, retention ponds and other facilities constructed to store runoff or carry it to a receiving stream, lake, ocean, or other waterbody. Other man-made features include yards and swales that collect runoff and direct it to the sewers and ditches. When most of these systems were built, they were typically designed to handle the amount of water expected during a 10-year storm. Larger storms overload them, and the resulting backed-up sewers and overloaded ditches produce shallow flooding. Another urban drainage problem occurs in the areas protected by levees. Being in floodplains, they are flat and do not drain naturally, especially when a levee blocks the flow to the river. To drain these areas, channels have been built and pumps installed to mechanically move the water past the levee. Often, these man-made systems do not have the capacity to handle heavy rains or intense storms.

Another challenge with stormwater infrastructure is related to recordkeeping. It is not uncommon for stormwater data to be incomplete in most jurisdictions and completely lacking in others. Quality of data differs from jurisdiction to jurisdiction; some are in GIS formats, while others are paper maps or as-builts that represent the infrastructure at a macroscale level. The condition of the assets may be lacking, and the maintenance history may not be available either. Stormwater assets may have been installed with no records, especially in rural areas, farm fields, and private property.

Walton County passed Ordinance No. 2008-06 that prohibits unauthorized discharges into storm drains or ditch systems. In addition, the Public Works Division is currently running a continuous public awareness campaign aimed at encouraging the adoption of best management practices (BMPs) for managing stormwater runoff. This initiative targets both the business community and the residents of Walton County.

To address the issue of flooding, Walton County has implemented several measures along the years, such as:

- Drainage Systems: The county has invested in the development and maintenance of drainage systems, including ditches, canals, and retention ponds, to manage stormwater runoff and reduce flood risk.
- Floodplain Management: Walton County has adopted floodplain management regulations and participates in the National Flood Insurance Program (NFIP) to encourage responsible development in flood-prone areas.
- Elevation Standards: New construction projects within flood zones are required to adhere to specific elevation standards to minimize potential flood damage.

- Emergency Response: The county has established emergency response plans to assist residents during flood events, including evacuation procedures and the provision of emergency shelters.

Key stormwater assets for the HUC and Walton County are indicated in **Error! Reference source not found.** and **Error! Reference source not found.**, respectively. Stormwater structures and management processes in the county consist of stormwater outfall, water wells, weir, pollutant control boxes, inlets catch basins, pipes culverts, ditch conveyance swales, structures, pipes and open conveyance.

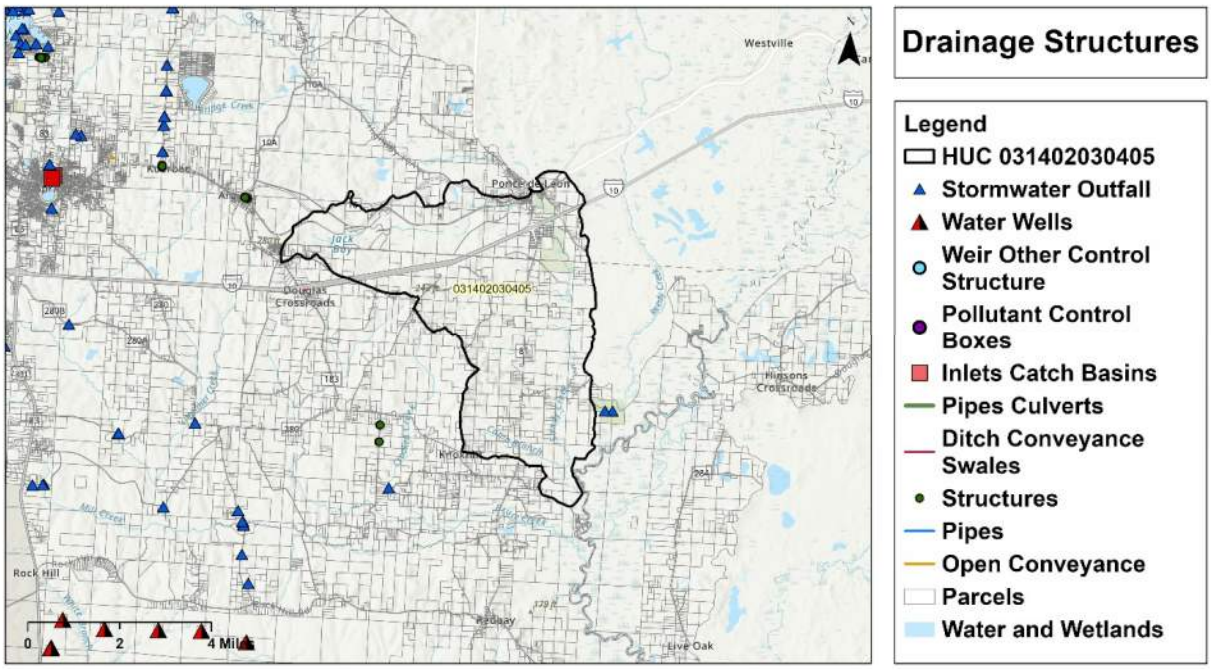

Figure 27. Stormwater Infrastructure for the HUC 031402030405. Processed by FAU.

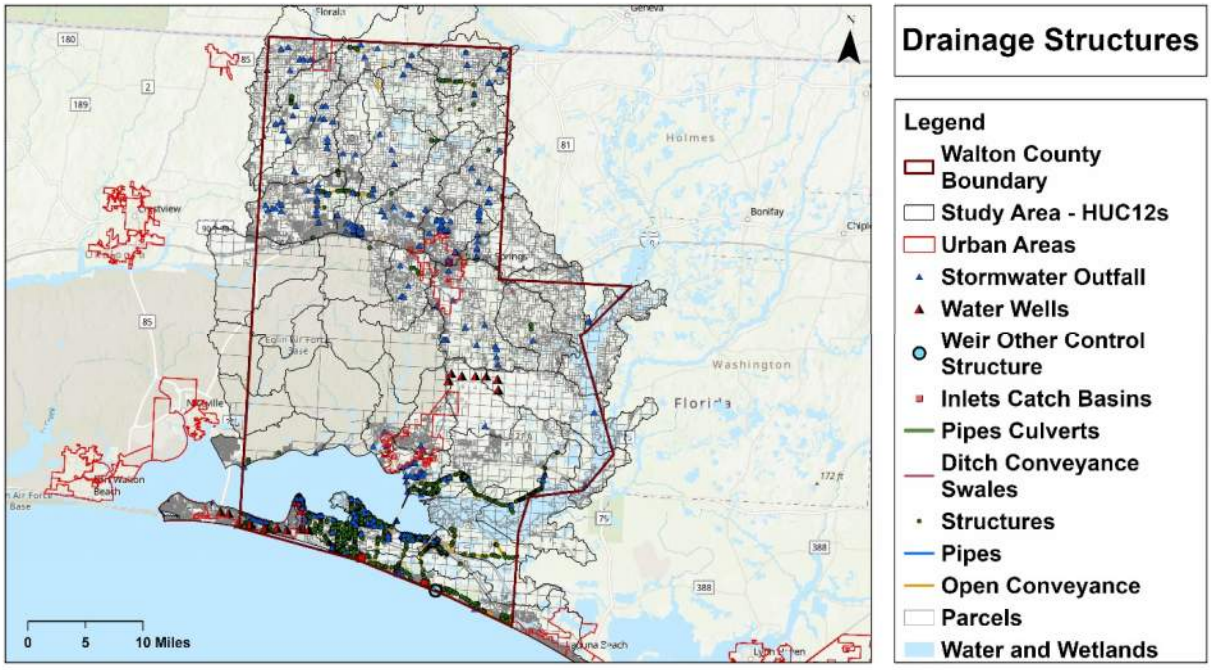

Figure 28.Stormwater Infrastructure for Walton County. Processed by FAU.

Although nature-based infrastructure might be installed, it is not certain. The stormwater system must maintain compliance with the stormwater regulations, which requires record-keeping, policy development, inspections and maintenance. The goals of such stormwater management may include:

- Best landscape practice;
- Control car washing contribution to pollution;
- Enforce the Stormwater Pollution Prevention Plan (SWPPP) by site evaluation, assessment, erosion and sediment controls, preventive maintenance, certification and inspection reporting for construction sites and city planning;
- Implement a hazardous material elimination system;
- Eliminate illicit dumping;
- Proactive and reactive catch basin inspections and maintenance;
- Street sweeping to control debris;
- Maintain swales to help prevent stormwater pollution flooding.

1.13 Data Gaps

FAU has developed comprehensive databases to address the information needed for the vulnerability assessment. These are included in **Error! Reference source not found.**. The data

can be used to model the impacts of flood routing during the storm of interest. As a result, the modeling pieces (discussed in Chapter 2) will include the following:

- Flood response model results (Cascade 2001)
- Flood risk/hazard mapping
- Vulnerability assessments to identify areas of concern for future repetitive losses

There is only one data gap for the area – existing stormwater infrastructure records are incomplete. However, for the purposes of this plan, this data gap does not limit the findings as there are two scales: 1) the sub-watershed level and 2) community hotspots. A neighborhood level vulnerability assessment will require the local infrastructure inventory.

Table 6. List of datasets collected by FAU as of List of datasets collected by FAU for the project (12/20/2020)

2.0 ASSESSMENT OF VULNERABLE AREAS

Defining flood risk due to compounding hydrographic influences is the central concern of this WMP. Modeling and assessment of vulnerability focused on the combination of a high-water table, heavy rains, and impervious conditions that can lead to localized nuisance flooding events. Through a previous survey with local officials, the number of days of continuous nuisance flooding that the public will tolerate before that flooding is considered destructive is about 4 days (E Science 2014).

For a large study area, small parts may actually be at risk. The point is to identify where further study might be needed. A screening tool accomplishes this goal applied to the sub-watershed scale to designate areas that are susceptible to periodic flooding events. Utilizing the information collected and analyzed in Chapters 1, analysis of flood vulnerability can be performed.

2.1 Historical and Existing Challenges

Walton County has faced various historical and existing challenges as well as natural hazards over the years. Some of these include:

- Hurricane and Tropical Storms: being situated along the Gulf Coast, Walton County is vulnerable to hurricanes and tropical storms, which can lead to damage to the built and natural environment, as well as poses risks to human and wild life.
- Coastal Erosion: The county's coastline is subject to erosion due to natural processes and human activities. Erosion can lead to the loss of beaches and threaten coastal structures and properties.
- Flooding: heavy rainfall, storm surges from hurricanes, and other factors can cause localized flooding, particularly in low-lying areas. Flood events can disrupt daily life, damage property, and impact transportation.
- Water Quality and Quantity: as in many coastal areas, managing water quality and maintaining an adequate water supply are ongoing challenges. Pollution from stormwater runoff and other sources can affect water quality, and groundwater resources need to be carefully managed to sustain the growing population.
- Wetland Loss: The county's wetlands face the threat of degradation and loss due to urban development and other human activities. Protecting these essential ecosystems is vital for maintaining biodiversity and mitigating flood risks.
- Urbanization and Development: Balancing the demand for development and growth with the preservation of natural habitats and resources is a persistent challenge. Unplanned

urbanization can lead to habitat destruction, increased runoff, and exacerbate flooding risks.

- Land Use and Zoning: Proper land use planning and zoning are essential to address issues related to population growth, infrastructure development, and natural hazard mitigation. Ensuring responsible development practices can help minimize risks.
- Invasive Species: Like many regions, Walton County faces the threat of invasive plant and animal species. These invasive species can disrupt local ecosystems, negatively impacting native flora and fauna.
- Sea-Level Rise: With rising sea levels due to climate change, coastal communities like Walton County's coastal areas are at greater risk of inundation and storm surges during extreme weather events.

The fast growth of the population and urban development in the coastal areas of the county exacerbates effort to protect open space for land percolation of water. While regulations are in place to reduce the influx of stormwater, the challenges will continue with development.

2.1.1 Existing Management Efforts in the Watershed

The county is under Northwest Florida Management District (NWFMWD) jurisdiction, which covers the Florida Panhandle region. The NWFMWD is responsible for managing and protecting water resources in its designated regions, which includes issues related to water supply, water quality, flood control, and natural resource conservation. Local governments have local stormwater utility infrastructure and planning/policy tools to reduce future flood potential. Most of the major projects to date have been focused on addressing the water quality issues and flooding due to extreme rainfall.

2.1.2 Critical Target Areas Identification

By modeling the HUC 031402030405 sub-watershed flood response to a series of rainfall events (plus king tides), and further classifying flood risk as the probability of inundation, it is possible to identify critical target areas. These areas are particularly vulnerable to flooding and are subject to further study through a scaled-down modeling approach. The screening tool is first applied at the greater watershed level to provide an initial risk assessment focused on the hydrologic response to a rainfall event given the unique characteristics and features of the sub-watershed or study area. The process is discussed later in Section 2.2 with results presented in Section 2.3.

2.1.3 Potential Preservation Areas

Walton County boasts several areas with high biodiversity value. These areas include the unique coastal dune lakes, which support diverse ecosystems and contribute to water quality along the

coast. Wetlands are crucial habitats that provide refuge for a variety of plant and animal species while acting as natural water filters. State parks like Topsail Hill Preserve and Grayton Beach State Park are valuable conservation areas with diverse coastal ecosystems. Additionally, preserving the Choctawhatchee River Basin is essential for the biodiversity of the region.

2.2 Vulnerability Maps

2.2.1 Screening Tool

The screening tool utilizes topographic data from various sources (Section 1.1), water table elevations (Section 1.2) and surface water gauges (Section 1.3) downloaded from the NWFWMD DBHYDRO website, tidal information for coastal areas obtained from the NOAA Current & Tides website (Section 1.3), soil maps obtained from the USDA (Section 1.4), and another key dataset as described previously in Chapter 1. The design storms are discussed in Section 1.6. The reason this is critical is that to do any modeling (as required by the CRS program), a screening tool should be used to identify regions with a high risk of inundation based on multiple collected datasets and hydrological models. **Error! Reference source not found.** shows how the GIS layers interface in the tool and how they are combined for spatial analysis.

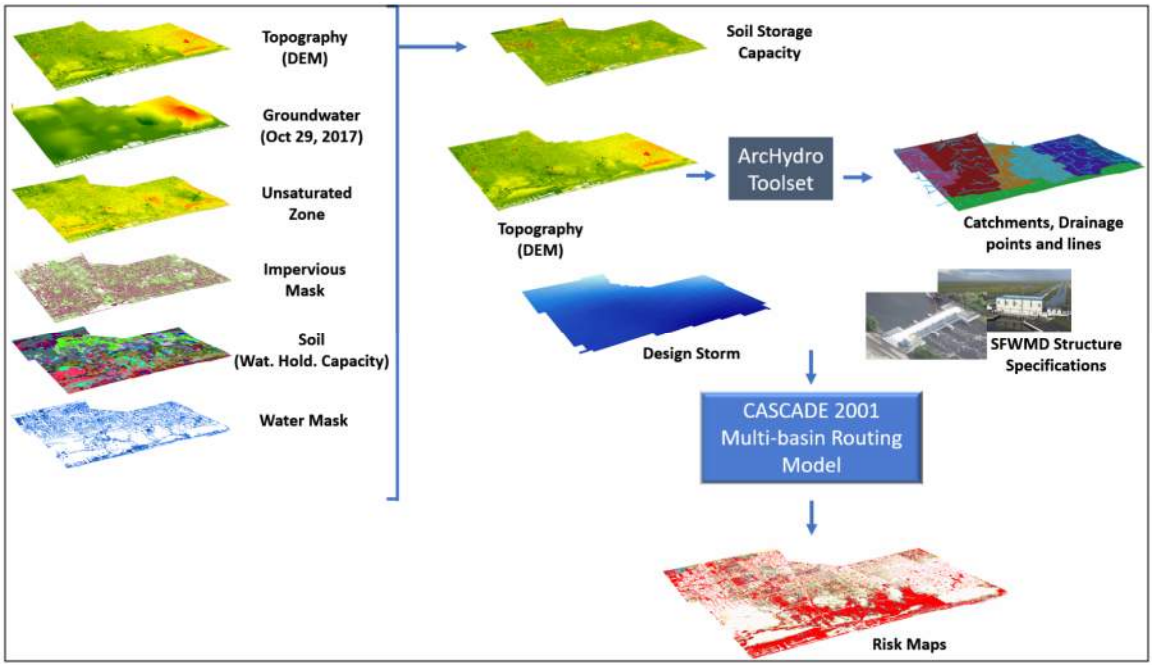

Figure 29. Screening tool methodology for creating flood risk maps.

The model chosen for this screening tool is Cascade 2001, which is a multi-basin hydrologic/hydraulic routing model developed by the SFWMD. The model permits the

investigator to run different storm events to determine flooding scenarios. The boundaries are critical for basin studies and must be chosen carefully. The following data layers collected in the prior section are processed to develop the input files for Cascade 2001:

- Topography
- Soils
- Development intensity
- Groundwater elevations
- Surface water/Outlet locations

The software creates a glass box where water rises to a certain level and then decreases. Running the simulation requires defining the basin (HUC or sub-HUC) and input of the following data:

- Area
- Portion of area above a given elevation
- Initial groundwater stage
- Longest travel time for the runoff to reach the most distance point of discharge
- Ground storage as estimated from the USDA gridded National Soil Survey Geographic Database (gNATSGO)

  Ground storage ≈ (Water holding capacity) × (Surface elevation – GW elevation)
  = 2 × (AWS for a soil layer of 0-150 cm) / 150cm × (Surface elevation – GW elevation)

- Available water storage (AWS) for a soil layer of 0-150 cm
- Average amount of precipitation that can be stored in the soil layer

The output from the model is an elevation surface that can be used to develop a flood map for the study area (**Error! Reference source not found.**), which shows the spatial distribution of probabilities of flooding during the modeled 1-day 100-year storm event.

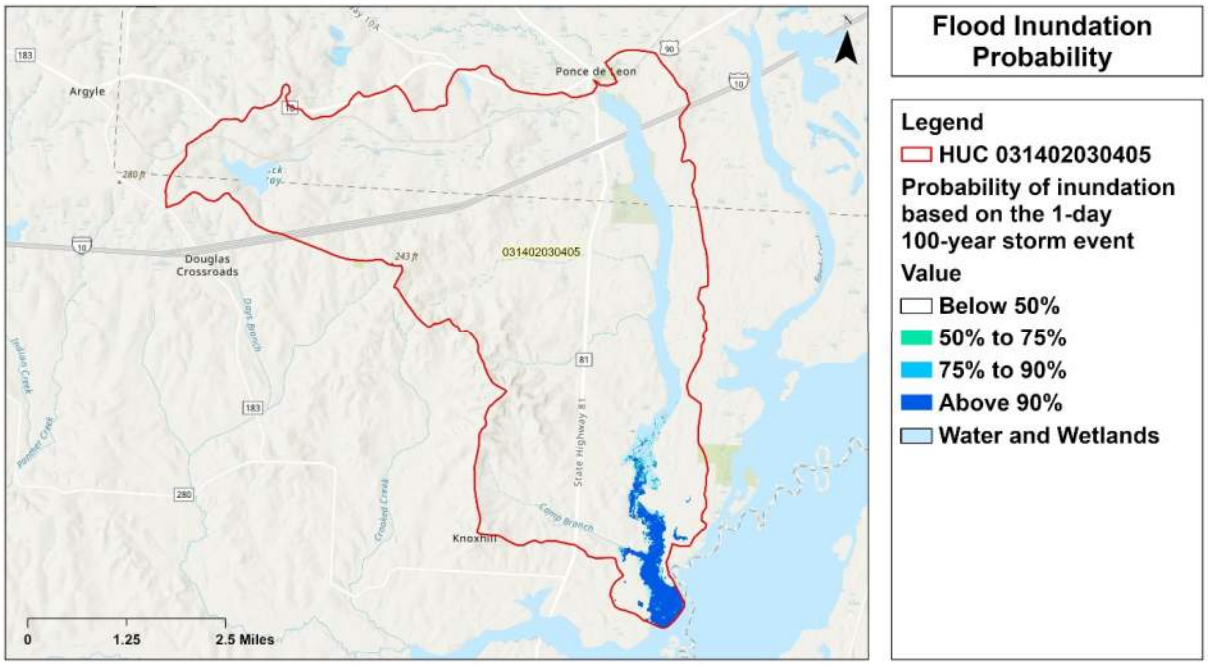

Figure 30. Probability of flood risk map during the modeled 1-day 100-year storm event for the HUC 031402030405, processed by FAU.

2.2.2 Identification of Vulnerable Areas

Given these assumptions and the Cascade 2001 outputs, the goal of this methodology is to produce a spatially-temporally quantified understanding of nuisance-destructive flood potential in the study area given observed values. Risk is a function of compounding geo-hydrological features, namely, surface water, groundwater, topography, build-out, and time of year. A GIS-based algorithm and spatial interpolation generated layers of the greatest observable hydrographic surfaces. These outputs were then compared with high resolution topographic LiDAR data to develop digital elevation models that reflect the observed risk landscape. These models can then be combined into Cascade 2001 to produce vector and volume information, in combination with soils, vegetation and impervious surfaces, allowing the observed model outputs to be extrapolated into a more predictive context.

To evaluate flood vulnerability at this scale, the analysis starts with a binary flooding surface (0 = below 50% chance of flooding; 1 = above 50% flooding) based on output from the screening tool for a specified design storm. Next, attributes of that raster based on "VALUE = 1" query are extracted using *Extract by Attributes* tool. Then the *Batch Project* tool was used to map critical facilities data to the common coordinate system (NAD83 UTM Zone 17N), unit = meters. Then a field was added using *Add Field* for [PriorityTier] = assigned Tier #1-4 value from the DOR codes

and [Area_sqmeter]. The critical facilities layers were then merged into a single layer to calculate the polygon geometry for [Area_sqmeter] using the *Merge* tool. Next, *Zonal Statistics as Table* is used to calculate the SUM of flooded values ("VALUE = 1") within each critical parcel. Output table has fields for SUM (i.e., total # of flooded pixels per critical parcel) and AREA in map units of square meters (since each pixel in the flooding surface has a cell size of 3-meters by 3-meters, each area is equal to the SUM value multiplied by 9 m^2). Using the *Join Field* tool, the SUM and AREA fields are joined to the merged critical facilities layer based on a key attribute, first renaming these fields for clarity (e.g., AREA_FLOODED_3d25y). Once all field data is included, the next step involves using *Export Table* to export the dataset as a CSV file. Note that non-flooded parcels have zero flooded area, so they receive a <Null> value from the zonal statistics tool. To replace null values with zeros, we use *Calculate Field* in the attribute table along with the following Python expression (replacing the respective field name): "0 if !AREA_FLOODED_3d25y! is None else !AREA_FLOODED_3d25y!". Next, the CSV file is saved as an Excel Workbook (.xlsx). The Range is converted to an Excel Table, and the columns are rearranged in the desired order. Finally, the "percent-flooded" columns are calculated as follows:

- PCT_FLOODED_3d25y = ([@[AREA_FLOODED_3d25y]]/[@[TotalArea_sqmeter]])*100
- PCT_FLOODED_1d100y = ([@[AREA_FLOODED_1d100y]]/[@[TotalArea_sqmeter]])*100

After this calculation, the table is sorted to show the higher priority tiers and higher percent-flooded values first. To reduce the number of critical facilities shown in the final table, a filter was created to show only critical facilities with 10% or more flooded area in the parcel during both storm events. Records with duplicate parcel ID numbers were removed from the table. The results of this procedure are discussed in Section 2.4 of this document.

With respect to dams and levees, for purposes of the NFIP, FEMA only recognizes systems that meet, and continue to meet, minimum design, operation, and maintenance standards that are consistent with comprehensive floodplain management criteria. The Code of Federal Regulations, Title 44, Section 65.10 (44 CFR 65.10) describes the information needed for FEMA to determine if a levee system reduces the risk from the 1% annual chance flood. FEMA has accredited levees and Provisionally Accredited Levees (that have a specified timeframe to obtain the necessary data to confirm the levee's certification status). If a levee system no longer meets Section 65.10, FEMA will de-accredit the levee system and issue an effective FIRM showing the levee-impacted area as a SFHA. FEMA coordinates its programs with USACE, who may inspect, maintain, and repair levee systems. USACE has authority under Public Law 84-99 to supplement local efforts to repair flood control projects that are damaged by floods. Like FEMA, USACE provides a program to allow public sponsors or operators to address levee system maintenance deficiencies. Failure to do so within the required timeframe results in the levee system being placed in an inactive status in

the USACE Rehabilitation and Inspection Program. Levee systems in an inactive status are not eligible for rehabilitation assistance under Public Law 84-99. There are no levees/dams listed in the sub-watershed study area.

2.3 Modeling Results

Error! Reference source not found. to **Error! Reference source not found.** are a series of maps that depict risk of flooding in the basin based on the following scenarios:

1. 3-day 25-year storm event. Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (**Error! Reference source not found.**)
2. 1-day 100-year storm event. Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (**Error! Reference source not found.**)
3. 1-day 10-year storm event. Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (**Error! Reference source not found.**)
4. 1-day 5-year storm event. Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (**Error! Reference source not found.**)

In all storm event scenarios, a moderate amount of flooding is noted at the creek entrance to the HUC. As this basin is not connected to the ocean and its altitude is above 20 feet, the HUC is expected to remain unaffected by sea level rise, therefore SLR scenarios were not computed.

The design storm simulation determined that approximately 2.3% of the HUC total area or 0.55 mi^2 has a probability of inundation above 50% for all four design storm scenarios, indicating a high expectancy to be inundated in all four scenarios. **Error! Reference source not found.** compares the four storm events.

Table 7. HUC 031402030405 expected inundated area by storm event.

Storm Event	Area with probability of inundation below 50% (Sq Mi)	Area with probability of inundation above 50% (Sq Mi)	Area with probability of inundation below 50% (%)	Area with probability of inundation above 50% (%)
3-day 25-year	23.52	0.55	97.7%	2.3%
1-day 100-year	23.52	0.55	97.7%	2.3%
1-day 10-year	23.52	0.55	97.7%	2.3%
1-day 5-year	23.52	0.55	97.7%	2.3%

Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations.
Processed by FAU.

2.4 Risk and Vulnerability

The screening tool modeling exercise from the prior section identified areas within the communities that are vulnerable to flooding. Higher priority concerns should be those properties or assets that are considered essential and need to be kept in service during a flooding event. All other improvements are local. To help with prioritization, the following is suggested:

- Tier 1 - Critical facility protection (water/sewer utilities, public safety, hospitals, schools, power, shelters)
- Tier 2 - Essential facilities (groceries, pharmacies, roadways)
- Tier 3 - Economic centers (protecting jobs)
- Tier 4 - At risk communities
- Tier 5 - Other urban/suburban property
- Tier 6 - Agriculture/public property/vacant/undeveloped

Error! Reference source not found. outlines the priority of land use based on DOR land use codes from the property appraiser's office and assigns an associated priority level to each parcel. Note that for residential property, identifying at-risk communities (income, age, disability, health) requires a further drilldown to the neighborhood level (i.e. wealthy neighborhoods with few older, poor health individuals would have a lower priority than at risk communities, which generally have lower value housing and denser development). In the latter case, more people are impacted, and those people have less ability to mitigate risk. Based on these priorities, the relative risk priority DOR land use codes were evaluated based on a scale of 1 to 6, where 1 is higher priority (more vulnerable) and 6 is the least priority (least vulnerable).

Table 8. Priority of Land Use based on (DOR) land use codes. Processed by FAU.

103	Parcels With no Values (Rail)	2

Having assigned the risk priority from 1 to 6 in the DOR codes and the percentage of the parcel that floods during the applicable design storm, properties that are more critical to the function of the community can be identified. The methodology is to first convert the DOR code priority tier to its inverse scale by the following equation:

Consequence of risk factor = 7 – DOR Code Priority Tier

The flood risk factor from the screening tool is interpreted based on flooding probability. We take all parcels in tiers #1-4 that have a greater than 50% chance of flooding during a particular design storm and calculate the percent of the parcel that would flood during that event. The percentage is converted to a 6-point scale termed as the Flood Risk Factor, shown in **Error! Reference source not found.**.

Table 9. Flood Risk Factor Classification.

Percent of Parcel Flooded	Flood Risk Factor
90-100%	6
80-89%	5
70-79%	4
60-69%	3
50-59%	2
<50%	1

The priority is further developed by assigning 75% of the importance to the consequence of flooding and 25% importance to flood risk, or three times the importance to the consequence of flooding to come up with a composite score as follows:

Flood Risk Factor × 25% + Consequence of Risk Factor × 75% = Composite Score

Example: 1 × 25% + 6 × 75% = 4.75

Those higher priority properties that received the higher composite score are where the mitigation strategies and financial resources should focus first.

2.4.1 Results

Error! Reference source not found. and **Error! Reference source not found.** depict the HUC 031402030405 sub-watershed priority of land uses showing the critical facilities that should receive priority The first map (**Error! Reference source not found.**) exclusively displays critical facility parcels within the HUC without any flooding. The second map (**Error! Reference source not found.**) overlays critical facilities onto the 1-day 100-year storm event scenario. **Error! Reference source not found.**is a mosaic showing critical facilities overlaid in the 1-day 100-year storm event for the whole county.

Additionally, **Error! Reference source not found.**illustrates the composite score based on 1-day 100-year storm event for the HUC, which is the result of the calculations explained above, pinpointing parcels that should be prioritized. It considers only parcels classified as 1 to 4 tiers, and within the 50% probability of inundation area. Lastly, **Error! Reference source not found.** is a mosaic showing the results for composite score overlaid in the 1-day 100-year storm event for the coastal area of Walton County. As the subwatershed is not coastal, the results based on 5 ft. SLR + 1-day 100-year storm event were not computed for the basin.

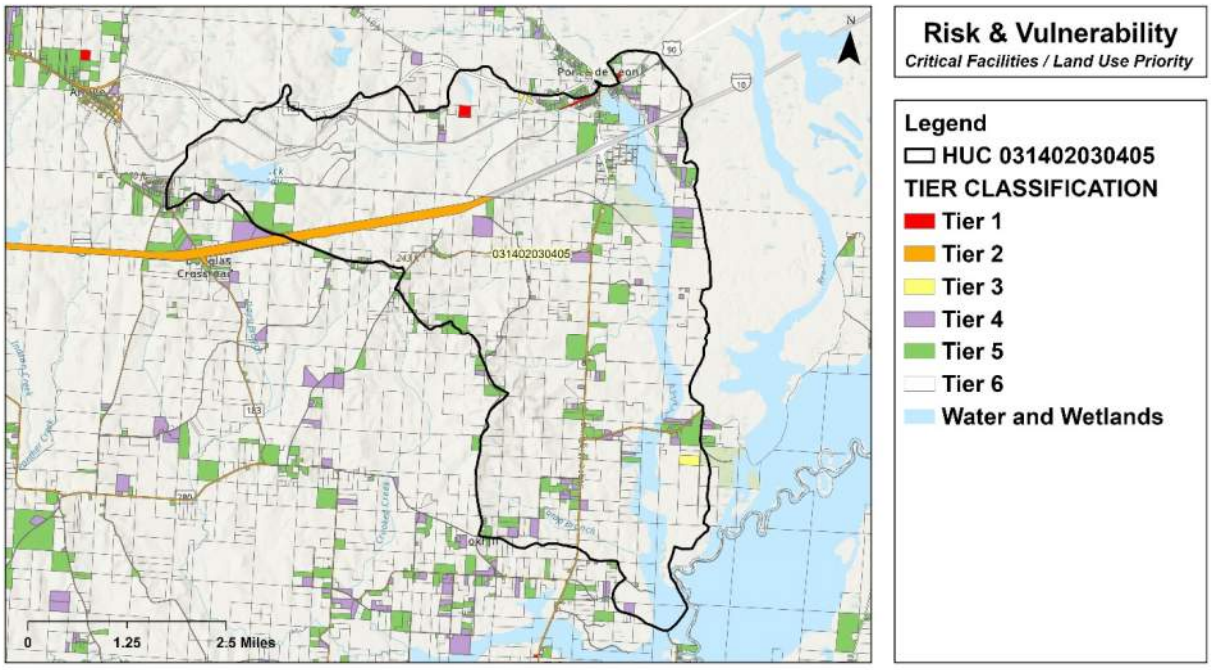

Figure 35. HUC 031402030405 sub-watershed Critical Facilities (priority of land uses) map. Processed by FAU.

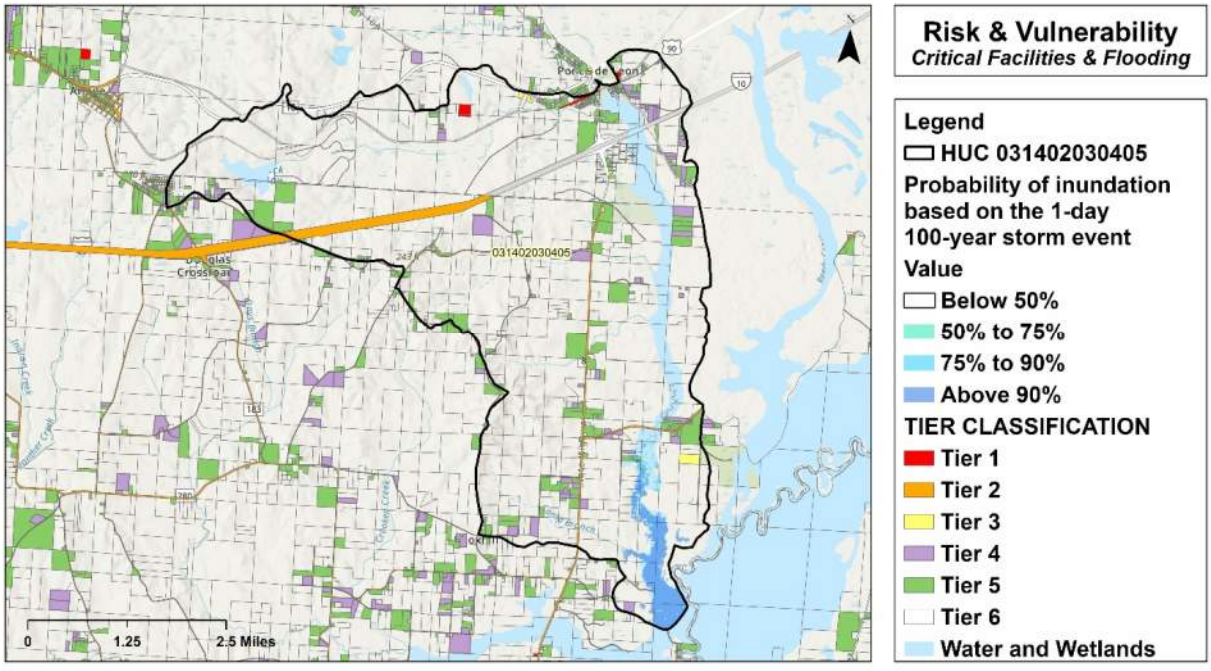

Figure 36. HUC 031402030405 sub-watershed Critical Facilities (priority of land uses) map overlaid on the 1-day 100-year storm event probability of inundation. Processed by FAU.

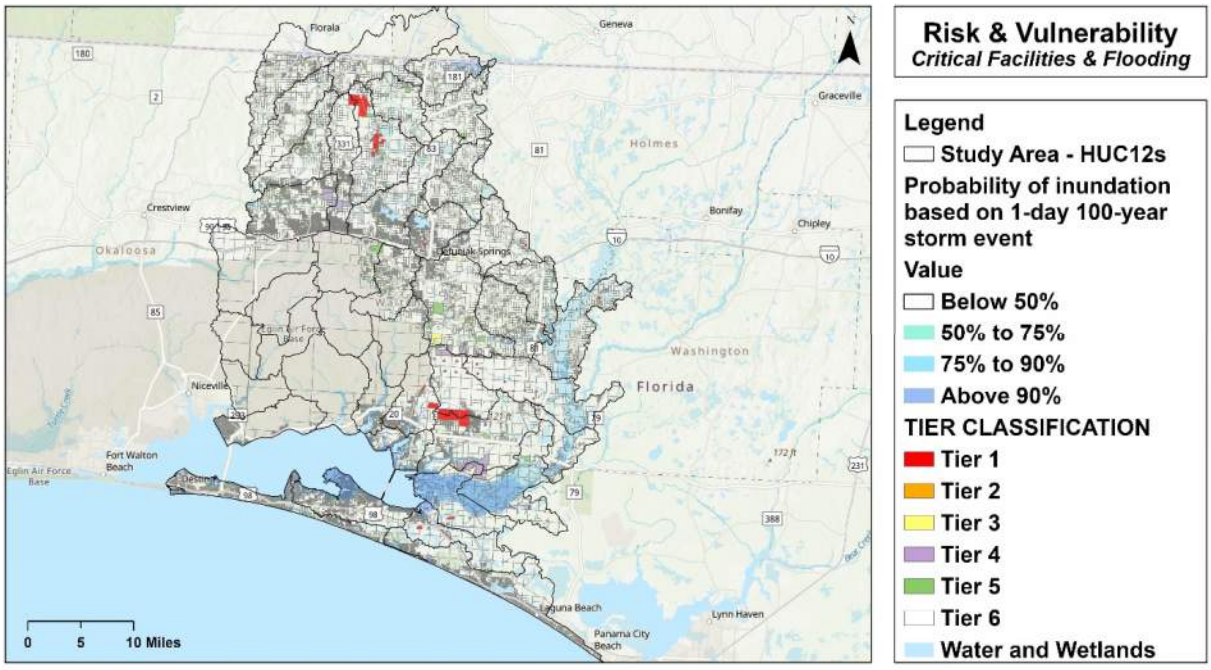

Figure 37. Walton County (mosaic) - Critical Facilities (priority of land uses) map overlaid on the 1-day 100-year storm event probability of inundation for Walton County. Processed by FAU.

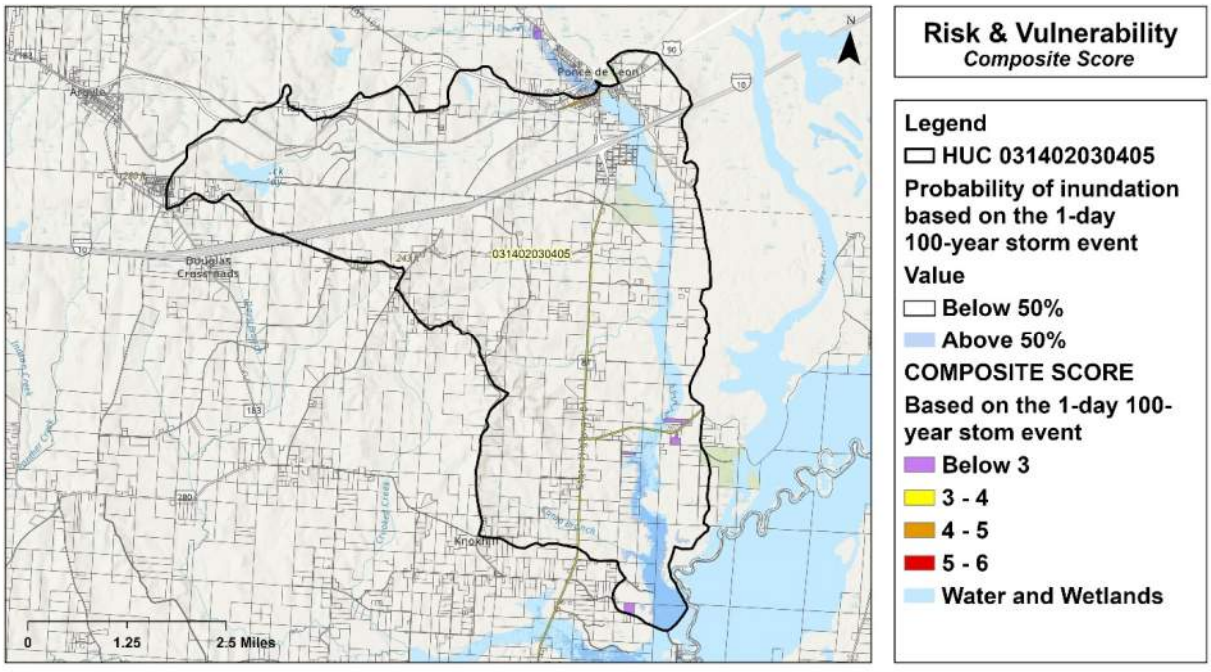

Figure 38. HUC 031402030405 sub-watershed Composite Score Risk map, with calculation based on 1-day 100-year storm event. Processed by FAU.

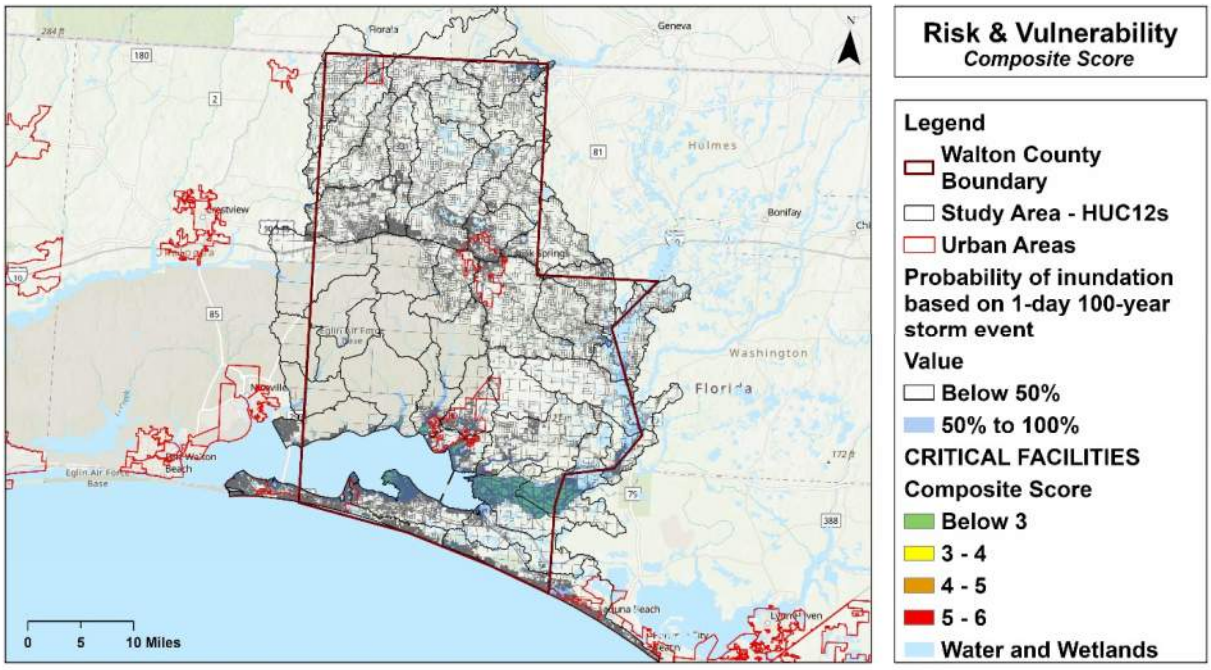

Figure 39. Walton County (mosaic) - Composite Score Risk map overlaid on the 1-day 100-year storm event probability of inundation. Processed by FAU.
Please note that due to the scale of the map, the composite score layer is not properly visible in this map.

Please note that the composite score results display outcomes exclusively for parcels within the flooding path area. Consequently, for parcels outside this flooding path, the composite results will be null. The composite score combines the flooding path area with the land use priority results to identify the most vulnerable areas deserving of priority.

2.4.2 Solutions

Chapter 5 of the Watershed Master Plan for Walton County describes a list of possible gray and green stormwater strategies to combat flooding that can be implemented as solutions for the county. The same solutions can also be applied at the HUC level, including HUC 031402030405. A summary of these flood mitigation strategies is listed in **Error! Reference source not found.**. For more detailed information, please see Chapter 5-5.3 (Solutions).

Table 10. List of possible gray and green stormwater strategies to combat flooding

Strategy Class	Implementation Strategy	Applications	Benefits	Cost	Barriers to Implementation
Green	Rainwater harvesting	Local, small scale, easily implemented in developed areas	Protects property, treats runoff	Under $5,000	Limited volume disposed of, so many are needed, maintenance
Gray	Pervious paving	Parking lots, patios, driveways, anything except paved roads due to traffic loading	Reduces roadway and parking lot flooding	$10-20/sf, requires bumpers and sub-base to maintain paver integrity	Must be maintained via vacuuming or the perviousness fades after 2-3 years
Green	Detention	Common for new development, but difficult to retrofit; limited to open areas	Removes water from streets, reduces flooding	$200K/ac	Land availability, maintenance of pond, discharge location Uses up land that could otherwise be developed
Gray	Exfiltration Trench	Any low-lying area where stormwater collects and the water table is more than 3 ft below the surface; densely developed areas where retention is not available, roadways	Excess water drains to aquifer, some treatment provided	$250/ft	Significant damage to roadways for installation, maintenance needed, clogging issues reduce benefits
Gray	Central sewer installation	All areas where there are septic tanks. Mostly a water quality issue	Public health benefit of reducing discharges to lawns, canals, and groundwater from septic tanks	$15,000 per household	Cost, assessments against property owners, property rights issues
Green	Flood prone property acquisition	Regional agency - could be any low-lying areas	Removes flood prone areas from risk	$2K-$100K/ac depending on whether it is already developed	Difficult to implement if occupied, issues with willing sellers, cost, lack of funds for acquisition

Strategy Class	Implementation Strategy	Applications	Benefits	Cost	Barriers to Implementation
Gray	Pump stations	Any low-lying area where stormwater collects, and there is a place to pump the excess stormwater to such as a canal; common for developed areas	Removes water from streets, reduces flooding	Start at $1.5 to 5 million each, number unclear without more study	NPDES permits, maintenance cost, land acquisition, discharge quality
Gray	Armored sewer systems	Any area where gravity sanitary sewers are installed	Keeps stormwater out of sanitary sewer system and reduces potential for disease spread from sewage overflows	$500/manhole	Limited expense beyond capital cost
Gray	Sea walls	Barrier islands and downtown coastal areas	Protects property	$1200/ft	Private property rights, neighbors
Policy	Changes in land use	Applicable universally	Achieves flood risk mitigation by adjusting permitted land use	Low but may incur private property rights conflicts and litigation	Private property rights conflicts and litigation
Gray	Roadway base protection	Low-lying areas, coastal communities	Protects roads and access routes	$1 million per lane-mile	Cost, adjacent properties become uninsurable
Policy	Enhanced elevation of buildings	Developers would implement this for new construction	Reduced flood risk	Varies	Potential issues with building structure or latticework, and existing homes that are not elevated

2.4.3 Impacted Adjustment Areas

In the evaluation of flood risk management strategies within the framework of the National Flood Insurance Program Community Rating System (CRS), the concept of impact adjustment plays a pivotal role in determining the extent to which CRS-credited activities or elements influence the vulnerability of a community's Special Flood Hazard Area (SFHA) and the structures located within it. It's important to note that while the usual results of impact adjustment are related to the SFHA area, in this specific analysis, it was used 1-day 100-year storm event inundation area performed by FAU instead.

In this context, the following table presents a breakdown of the impact adjustment calculations for a 1-day 100-year storm event inundation. The values are expressed in acres and depict the areas of interest as well as the deductions considered in the evaluation process.

The outcomes of these calculations provide valuable insights into the impact adjustment scenarios:

With ALL State Lands:

This scenario reflects the remaining inundation area after accounting for deductions A, B, and C. It represents the effect of CRS-credited activities without considering the influence of state lands in managing flood risks.

With NO State Lands:

In this case, the remaining inundation area is determined by considering all deductions, including state lands (both open space and not open space – see **Error! Reference source not found.**).

These calculations highlight the dynamic nature of impact adjustment within the CRS framework. By accurately gauging the influence of individual elements, the system ensures that credit allocations align closely with a community's efforts in flood risk mitigation.

Table 11. Impacted Adjustment Areas for HUC 031402030405. Processed by FAU.

AREAS	**ACRES**
HUC-12 Sub-watershed: 031402030405	15410.98
All of the 1-day 100-year storm event inundation	**355.06**
Subtract	
A. Bodies of Water in 1-day 100-year inundation > 10 acres	0.00
B. Federal Land in 1-day 100-year inundation > 10 acres	0.00
C. Reservation/Tribal Land in 1-day 100-year inundation > 10 acres	0
D. State Land in 1-day 100-year inundation > 10 acres that is open space	5.47
E. State Land in 1-day 100-year inundation > 10 acres that is NOT open space	0.00
The remainder is either:	
With ALL State Lands: All of the 1-day 100-year inundation minus (A+B+C) or	355.06
With NO State Lands: All of the 1-day 100-year inundation minus (A+B+C+D+E)	349.58

2.4.4 Repetitive Loss Property Map

A Repetitive Loss (RL) property is a building that has had two or more loss or damage due to a specific hazard, such as floods, hurricanes, or other natural disasters, over $1,000 each, paid by the National Flood Insurance Program (NFIP) within any ten-year period since 1978. There are more than 122,000 RL properties in the nationwide (FEMA, 2005).

These data are essential for assessing the vulnerability of certain areas to recurrent losses and for developing strategies to mitigate the risks. However, due to privacy concerns, the data cannot be openly shared with the public. For this reason, the data were converted into a hot spot analysis map. These maps, instead of identifying the specific location of the repetitive loss properties, highlight clusters of repetitive loss claims and areas where the probability of repetitive losses is higher than would be expected by random chance. In other words, it helps pinpoint locations that have a higher concentration of properties prone to repetitive losses. **Error! Reference source not found.** indicates the results from hot spot analysis in point data, showing aggregated counts, and raster data, showing the estimated probability of repetitive loss.

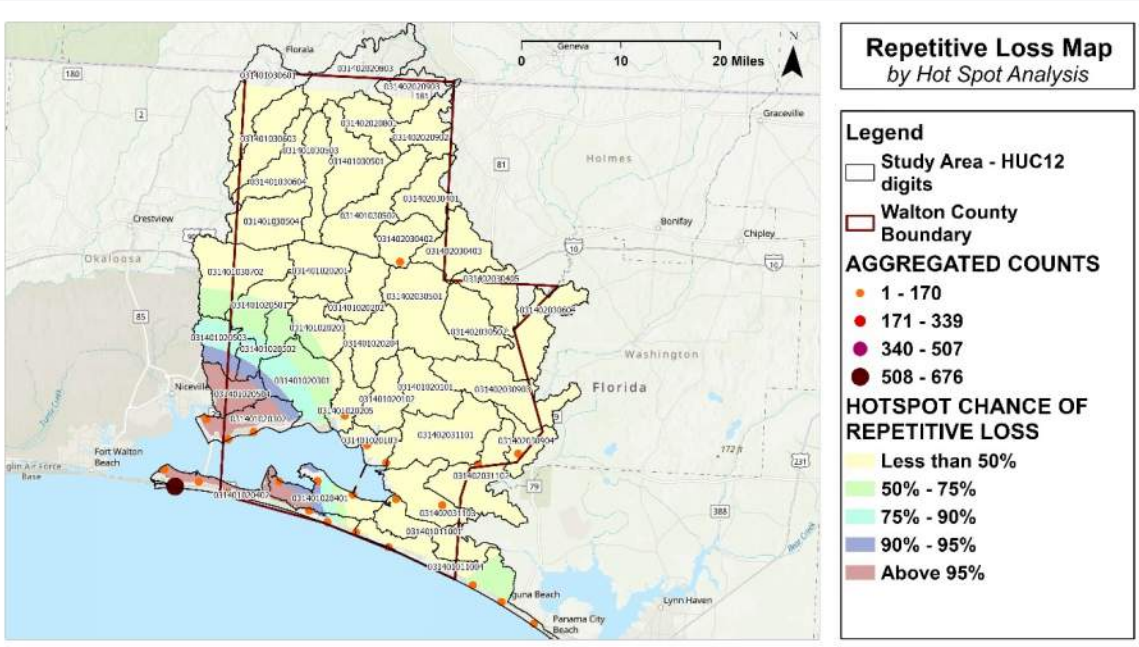

Figure 40. Repetitive Loss map for Walton County by Hot Spot Analysis. Processed by FAU.

2.4.5 Priority Projects

Although there are a good amount of parcels falling within tiers classification 1 to 5 priority of land uses, only a few of them are within the flooding zone, once flooding in the area is relatively minor and not alarming. Consequently, when considering the composite score, it is notable that most of the results are null. There are only nine exceptions within the basin: a utility parcel within score 4-5, four roads (Sandy Creek Landing Road, Highway 81, River Rd, and Highway 181) within score 3-4, and four mobile home parcels, all of them with scores below 3.

X.0 EXECUTIVE SUMMARY

The goal of the appendices to the watershed plan are to outline the issues associated with the individual HUC12s that contribute or impact the community's flood vulnerability and there for its flood protection efforts. Floodplain analysis includes developing a watershed model and identifying associated inundation polygons. It builds upon information generated from the watershed evaluation so that planning and management decisions can be formulated.

This appendix describes the issues and modeling associated with one of the HUC12s that affects Walton County. In developing the County-wide plan, this HUC 12 was analyzed so as to determine how it brings or removes floodwaters from the County. For the NFIP process the goal is to analyze all communities at the HUC12 level. From a community perspective the HUC12 is less useful to residents than a community-wide plan. Hence in all cases the HUC12 results were mosaicked into the community-wide plan. Details can be found in the HUC12 appendices, some of which were brought into the community plan.

To reduce redundancy, information of the plans, ordinances, policies and regulations were rolled up to the community-wide plan and will not be repeated in the appendices. Likewise, the community wide mapping was parced for HUC12 use.

1.0 WATERSHED CHARACTERIZATION

In this section, key aspects of the watershed are characterized. This is important for later being able to identify the most vulnerable areas and to mobilize resources to implement an action plan. Understanding the characteristics of the watershed involves gathering existing information and data sets from previous planning efforts. It is important to note that this step is iterative and ongoing as new data are generated and projects are implemented and monitored.

To assess the historical and current conditions of the study area, the following existing data sets that characterize the physical and natural features of the watershed were obtained for each HUC-12 subwatershed in the study area:

- Topographic data (LiDAR)
- Relevant waterway locations
- Groundwater levels
- Soils data
- Land uses including vacant land, wetlands, impervious, etc.
- Precipitation records
- Catchment delineations for flood routing

In addition, the FEMA flood maps must be obtained, and the storm of interest must be identified for screening purposes (1-day, 2-year, 5-year, and 100-year events as well as the 3-day 25-year storm event to achieve class 4 in the CRS Manual). In developed areas, many sources of data are already available – the key is putting the key datasets in a format that can queried for screening to identify the priority areas of the watershed. Table 6 is a summary of datasets available at cwr3.fau.edu that were used to construct this plan.

This watershed master plan is a drilldown of the larger Walton County TMDL region, which involves 42 HUC 12-digit sub-watersheds (**Error! Reference source not found.**). **Error! Reference source not found.** shows Walton County Drainage Network and the location of urban areas (cities and towns). In **Error! Reference source not found.**, the HUC-12 digits (031402030501) is highlighted among all the HUCs to help identifying its location.

The city of DeFuniak Springs shares a portion of its boundary with the basin. Demographics data and other considerations of DeFuniak Springs, along with other cities in Walton County, will be discussed later.

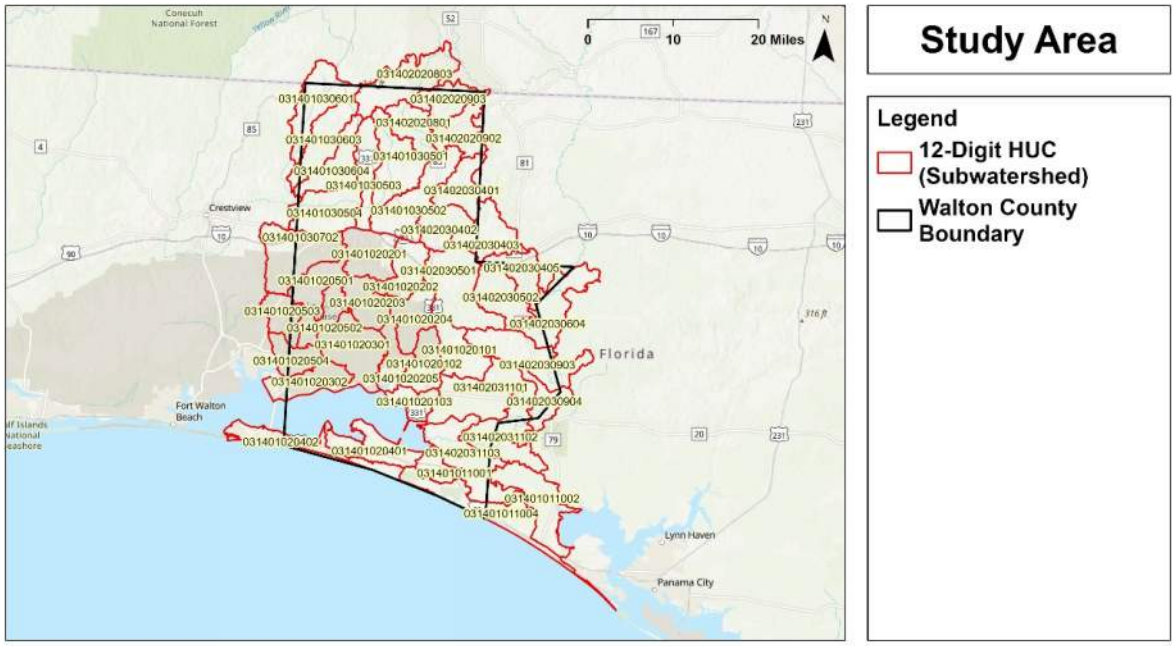

Figure 1. Walton County and all HUCs 12-digit subwatershed, processed by FAU.

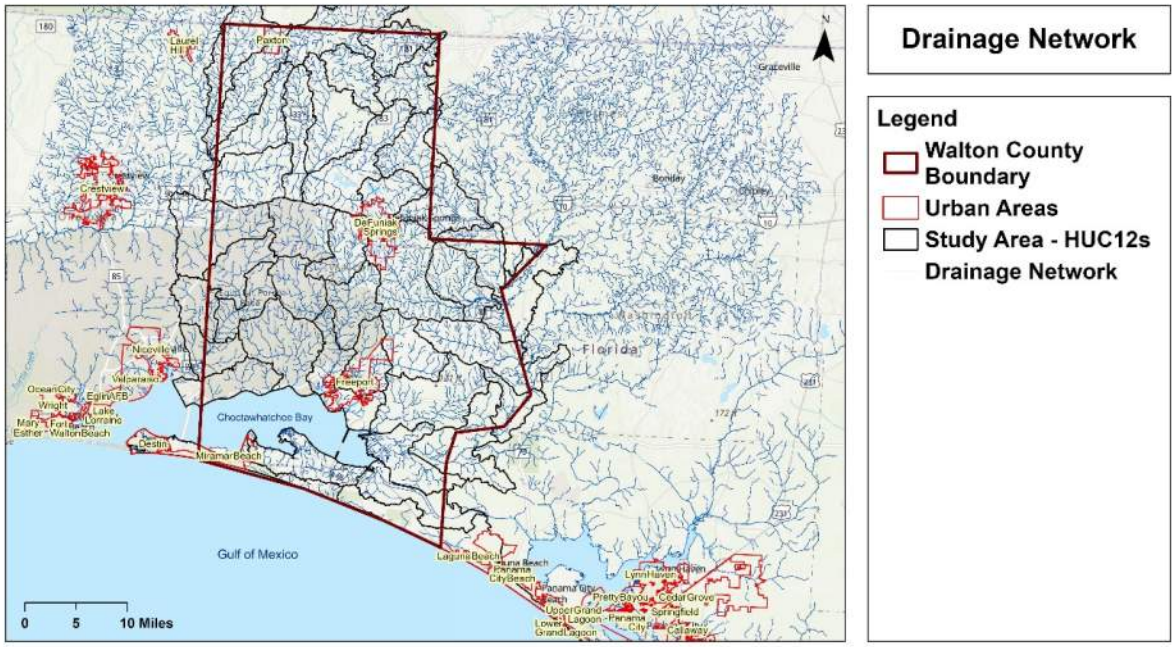

Figure 2. Walton County Drainage Network and urban areas (cities and towns), processed by FAU.

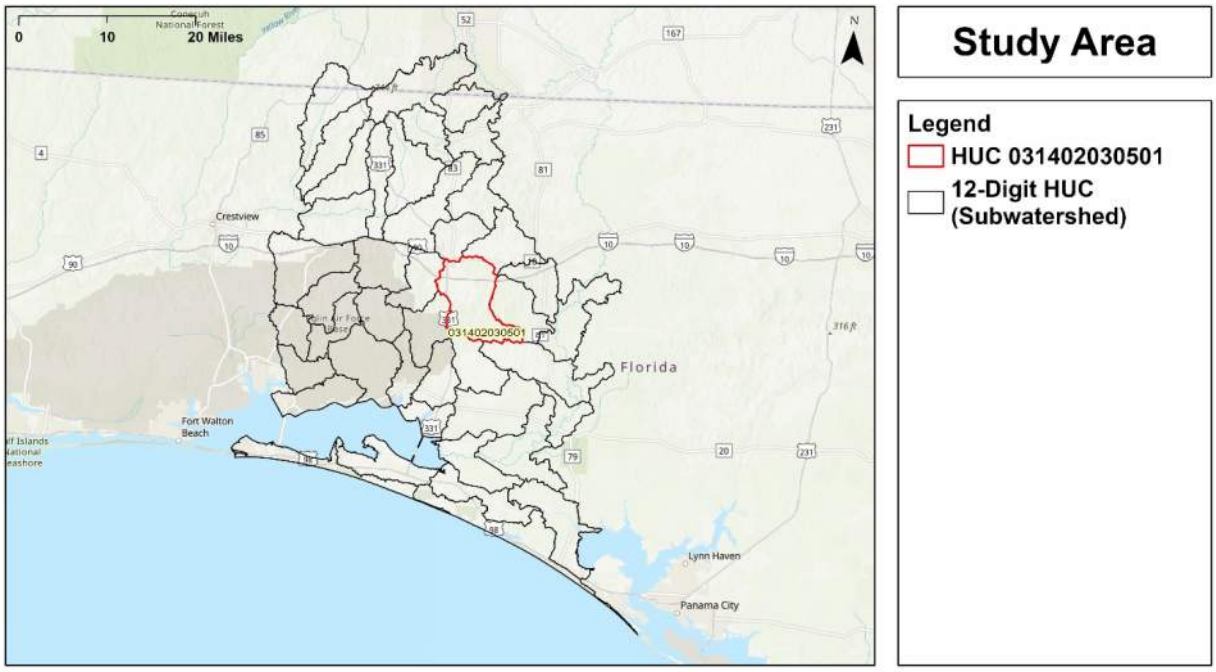

Figure 3. HUC 031402030501 sub-watershed location.

Located in the northwestern region of Florida, Walton County has 1,037.7 square miles of land and it is the 12th largest county in Florida by area, while also sits the highest point in the state, with a height of 345 feet in its northern end. With a population of 75,305 residents according to

the 2020 census and an estimate population in July of 2022 of 83,304, the county has experienced consistent growth within the past several years, driven by factors such as tourism, retirement migration, and regional population dynamics. The county was the residence for 55,043 people according to Census 2010, which leads to a percent change of 36.8% in 10 years, between 2010 and 2020, and a percentage change of 10.6% in two years, between 2020 and 2022 (United States Census Bureau).

The surge in population, particularly in the southern part of Walton County, has resulted in a corresponding expansion of infrastructure to cater to the growing needs. Essential facilities such as potable water systems, wastewater treatment plants, electrical utilities, roads, and schools have been developed to support this increasing population. However, the infrastructure expansion has brought about a significant change in the natural environment. Prior to the existing development , tropical cyclone impacts would be mitigated by natural barriers such as vegetated sand dunes, wetlands, and deserted beaches, which would absorb some of the destructive forces. Now, with the proliferation of costly infrastructure and residential dwellings in coastal areas, these storms pose a higher risk of potential damage. The very areas where development is occurring are becoming more vulnerable to the impact of severe storms, highlighting the importance of considering and implementing adequate measures to address potential storm damage in these coastal regions (Walton County Local Mitigation Strategy Plan, 2015).

Demographically, Walton County presents a heterogeneous age distribution, encompassing a blend of younger and elderly cohorts. The median age of approximately 44 years reflects the presence of both younger families and retirees seeking a serene and picturesque environment. Ethnically, the county' population is predominantly White with smaller yet notable populations of Hispanic/Latino, African American, and other racial/ ethnic groups.

Economically, the tourism sector stands as a dominant force in Walton County, constituting 23.4 percent of the workforce, according to Walton County Economic Development Alliance in 2011, due to its renowned beach destinations, such as Santa Rosa Beach, Miramar Beach, and the New Urbanist Communities of Seaside and Rosemary Beach. Following closely behind is the trade, transportation & utilities sector, accounting for 20.3 percent of employment, while construction stands at 10.0 percent in third place. Education, health care services, and public administration also play significant roles within the top five employment sectors, reflecting the diversified economic landscape of the county (Walton County Local Mitigation Strategy Plan, 2015).

The natural environment in Walton County contributes to its distinctive appeal to visitors and tourists. The county's coastal environment along the Gulf of Mexico showcases picturesque vistas, including white sand beaches, undulating dunes, and coastal dune lakes. These lakes, a rarity worldwide, provide unique ecological habitats. Walton County is also committed to environmental conservation, with designated protected areas comprising state parks, forests, and wildlife management zones. These preserved landscapes offer abundant opportunities for recreational activities, including hiking, fishing, and birdwatching.

The presence of wetlands and waterways further enhances the natural attributes of Walton County. Various rivers and creeks alongside Choctawhatchee Bay permeate the landscape, fostering

diverse ecosystems and serving as crucial habitats for a wide range of wildlife species. This rich natural heritage encourages exploration and nurtures an appreciation for the environment.

DeFuniak Springs serves as the county seat and boasts a diverse economy. Anchored by sectors such as healthcare, education, retail, government services, and a thriving small business community, DeFuniak Springs offers a range of employment opportunities. Surrounded by the natural beauty of forests, lakes, and wetlands, the city enjoys the presence of Lake DeFuniak, a noteworthy natural resource. With a population of approximately 5,100 residents, DeFuniak Springs is a vibrant city featuring a mix of economic activities. The land area of DeFuniak Springs is approximately 12.6 square miles (32.7 square kilometers).

Freeport boasts a diverse demographic profile, and a developing economy. The city is situated along the shores of Choctawhatchee Bay, which provides opportunities for recreational opportunities and supports local ecosystems. Surrounded by lush forests and intersected by waterways, Freeport enjoys a rich environmental setting. In terms of economics, Freeport's economy is in a phase of growth and diversification, with sectors including healthcare, education, retail, and small businesses. The city is also strategically positioned for future economic expansion due to its proximity to major transportation corridors. Demographically, Freeport is a close-knit community with a population of approximately 2,600 residents, comprising a mix of permanent residents, retirees, and individuals seeking a suburban or rural lifestyle. The city reflects a diverse demographic composition, showcasing a variety of cultures, and backgrounds. Freeport occupies a land area of about 13.6 square miles (35.3 square kilometers)

Further along the coast, Miramar Beach stands as a coastal gem known for its tourism and hospitality industry. Luxury resorts, vacation rentals, gourmet restaurants, high-end retail shops, and entertainment venues thrive within this bustling city. Miramar Beach's main attraction lies in its stunning white sand beaches along the Gulf of Mexico, providing endless opportunities for beach activities and water sports. Its boundaries extend into neighboring Okaloosa County, attracting a blend of permanent residents, vacation homeowners, and rental property occupants. Miramar Beach, including its neighboring areas, covers an estimated land area of around 4.7 square miles (12.2 square kilometers).

Continuing along the Gulf Coast, we encounter Santa Rosa Beach. This coastal community is renowned for its vibrant tourism industry, offering a plethora of accommodations ranging from upscale resorts to charming vacation rentals. Its demography reflects a mix of permanent residents, seasonal visitors, and individuals seeking a coastal lifestyle, resulting in a diverse and dynamic community. Santa Rosa Beach spans a larger area compared to other cities in Walton County, with an estimated land area of approximately 31.2 square miles (80.8 square kilometers).

A summary of the existing CRS classifications for the communities in the study area is is listed in **Error! Reference source not found.**. No cities in Walton County are listed in the FEMA Community Rating System Eligible Communities.

Table 1: Community Rating System for Walton County. Effective April 1, 2023.

Community #	Community Name	CRS Class Rating	Premium Discount for SFHA	% Discount for Non- SFHA	Status
120317	Walton County	6	20%	10	Cycle

Based on the the Level 1 land use for Walton County, only 7.07% of the land use in the county is urban and built up, and water/wetlands makes up 29.16% of the land use. The majority of land is upland forest, with 48.3%, as shown in **Error! Reference source not found.**.

Table 2. Land use table for Walton County (2023 Florida Geographic Data Library (FGDL)).

Level 1 Land Use-Land Cover Type	Area (Acres)	Percentage of Total

Wetlands	153759.9055	20.82%
Total	**738687.9147**	**100.00%**

Walton County has a history of flooding and has implemented various measures for flooding mitigation over the years (see section 2.12 for more details). The County has experienced flooding primarily due to heavy rainfall events and proximity to large water bodies such as the Gulf of Mexico, Choctawhatchee Bay, and numerous rivers and creeks. The topography of the region, with low-lying areas in the coastal areas and wetlands, also contributes to flood vulnerability. The proximity to the ocean (Gulf of Mexico) makes the county vulnerable to sea level rise. Over the years, Walton County has faced multiple flooding incidents, including:

- March 1997: Heavy rainfall led to significant flooding throughout the county, resulting in property damage and road closures.
- April 2009: Intense storms caused widespread flooding, damaging homes and infrastructure and resulting in the declaration of a state of emergency.
- April 2014: Heavy rainfall caused severe flooding, leading to the evacuation of some residents and the closure of roads.

Today, the goal of a stormwater management system in many communities is to keep the community as a place to live and do business while limiting risk from damage due to flooding. The short-term impacts from stormwater include flooding in low-lying areas and standing water in areas with limited soil storage capacity. Less common, but of increasing frequency, is the potential for extensive inundation of some areas, especially low-lying areas, during periods with high groundwater levels and groundwater impacted by sea level rise. As a result, there is a need to

understand the economic impact of flooding events and to create cost-effective stormwater infrastructure and policy solutions to protect property. This means preserving as much property and economic activity as possible without disrupting current activity or expending funds on inappropriate projects with limited long-term or social value.

1.1 Surface Topography

Topography is a key parameter that influences many of the processes involved in flood risk assessment, and thus, up-to-date, high-resolution, high-accuracy elevation data are required. In order to meet the requirements for FEMA Risk Mapping, Assessment, and Planning (RiskMAP), 1-meter (2015 to present) and 1/9 arc-second (~ 3-meter) (2010 -2015) LiDAR DEMs were acquired. The 1 m × 1 m LiDAR tiles were kriged to create a topographic map of the study area (**Error! Reference source not found.**). This accuracy meets the 3DEP Quality Level 2 vertical root mean square error accuracy threshold of ±10 cm for FEMA (Arundel et al., 2015). The LiDAR used for this basin was 2016.

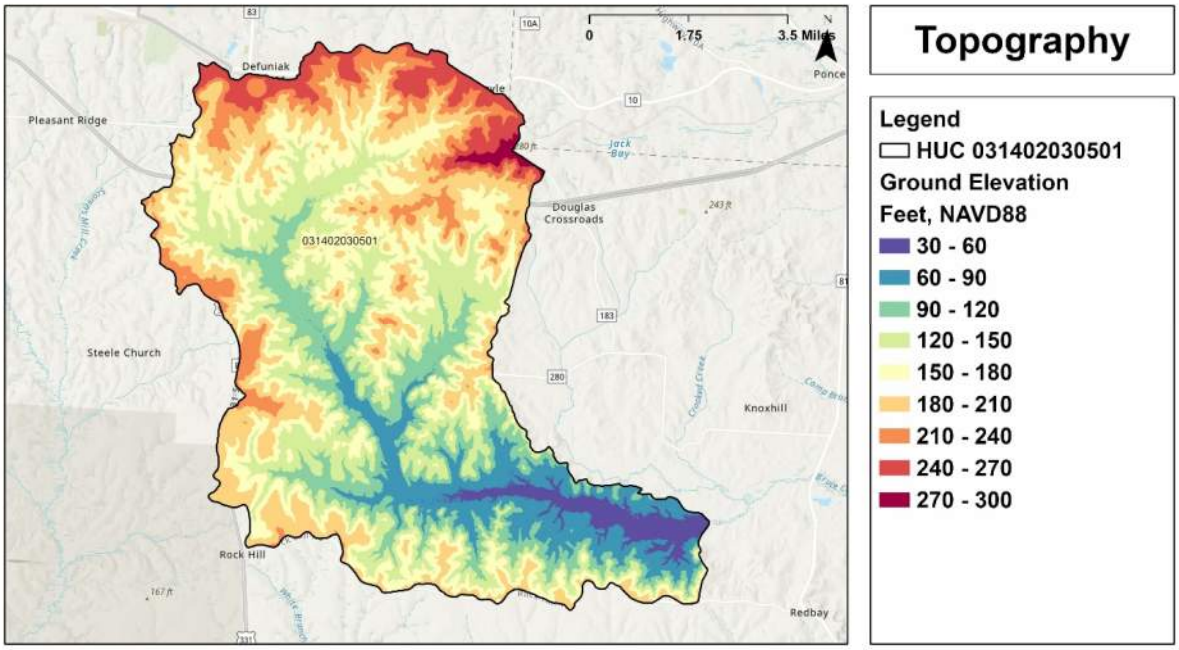

Figure 4. Topographic map of the HUC 031402030501 sub-watershed, processed by FAU.

1.1.1 Geomorphological Considerations

Walton County's coastal area is characterized by the presence of barrier islands, extensive sandy beaches, and coastal dune systems. These features are influenced by the dynamic processes of

wave action, tidal currents, and wind-driven sediment transport. The shoreline is subject to natural changes, including erosion and accretion, which significantly shape the coastal geomorphology. Inland Walton County exhibits a mix of wetlands, forests, rolling hills, and rivers. These landforms are influenced by a combination of factors, including underlying geology, fluvial processes, and the region's hydrological regime.

Like many areas in Florida, Walton County is underlain by limestone formations. The specific composition and properties of these limestone formations in Walton County may vary. However, limestone is generally known for its porous nature, which allows for the absorption and storage of water. Underground aquifers within the limestone formations can hold significant volumes of freshwater, contributing to the region's water resources.

For context, the FIRM panel index of HUC 031402030501 sub-watershed is shown in **Error! Reference source not found.**.

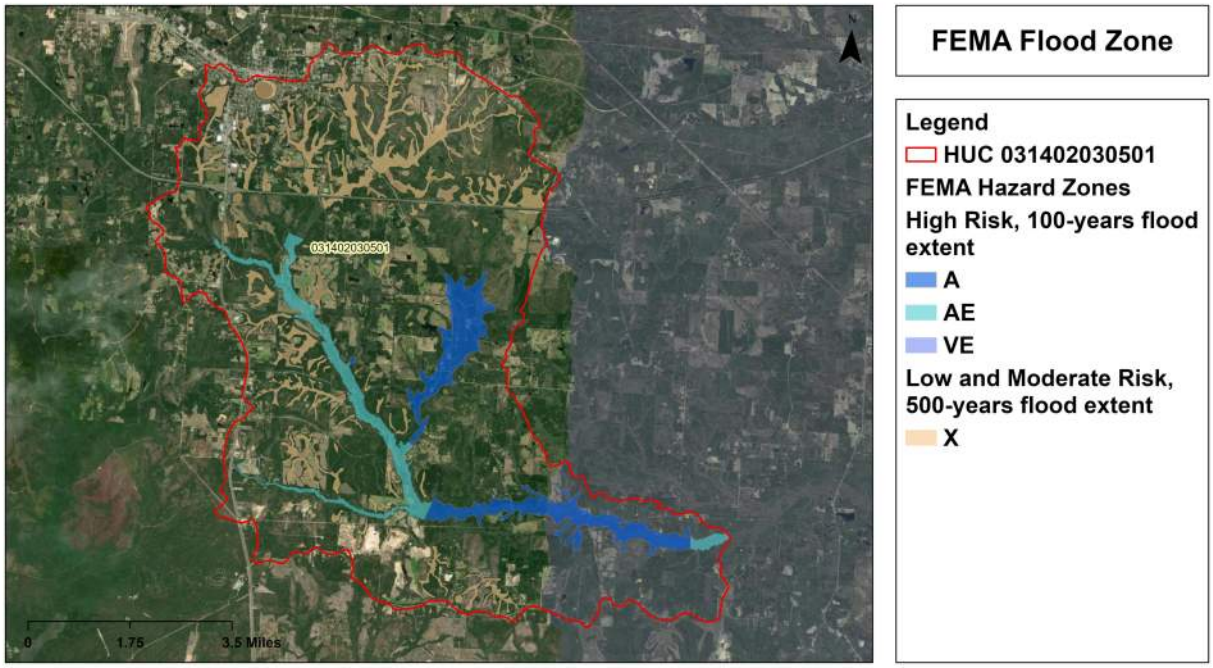

Figure 5. FEMA Flood Zone map (2020) for HUC 031402030501 sub-watershed, processed by FAU.

1.1.2 Waterway Features

In Walton County, Florida, the waterway features are primarily influenced by the presence of rivers, creeks, bayous, and the proximity to the Gulf of Mexico. To the south of Walton County lies the Gulf of Mexico. Sandy beaches, barrier islands, and the open waters of the Gulf itself characterize the coastline along the Gulf. The Gulf of Mexico influences the coastal processes,

including wave action, tidal currents, and sediment transport along the shoreline. The combination between sea level rise and King tide would have detrimental consequences for the county costal area, including the sub-watershed 031402030501 as it will reach the area thought Choctawhatchee Bay.

Walton County is home to several rivers and creeks that meander through its landscape. These waterways provide drainage for the inland areas and contribute to the overall hydrological system. Examples of significant rivers in the county include the Choctawhatchee River and the Shoal River. In addition, Walton County features bayous and estuaries that connect inland water systems to the Gulf of Mexico.

Choctawhatchee Bay serves as a vital estuarine ecosystem, where freshwater from rivers and creeks mixes with the saltwater from the Gulf of Mexico, serving as a vital estuarine ecosystem. This unique brackish water environment supports a rich diversity of flora and fauna, including various fish species, shellfish, migratory birds, and wetland vegetation, contributing to the overall biodiversity of the region. It also plays a significant role in the local economy of Walton County as it supports commercial and recreational fishing industries, providing livelihoods for local fishermen and contributing to the seafood industry, while also offering a range of recreational opportunities for residents and visitors alike, such as boating, kayaking, paddle boarding, and sailing. **Error! Reference source not found.** shows the bathymetry offshore.

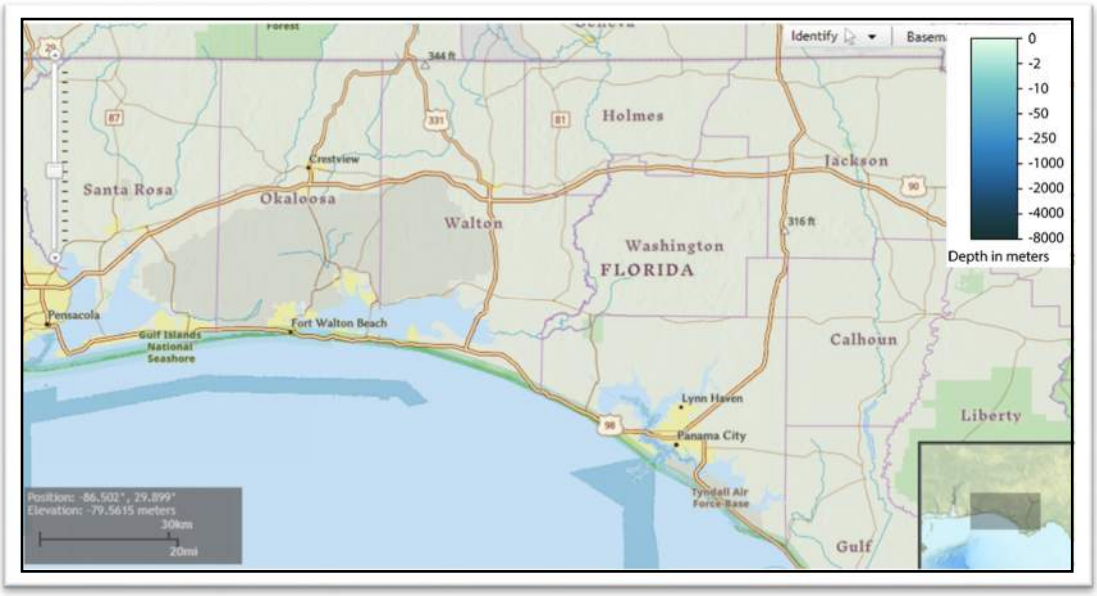

Figure 6. Bathymetry map of the shore of Walton County and surrounding counties of Florida Panhandle. Source: ncei.noaa.gov/maps/bathymetry/

Numerous tributaries exist throughout both the freshwater and estuarine portions of the watershed and can influence the overall hydrology of the area depending on rainfall and regional hydrological

conditions. **Error! Reference source not found.** shows the location of all four surface water stations along with ground water stations (wells) and the drainage network of Walton County.

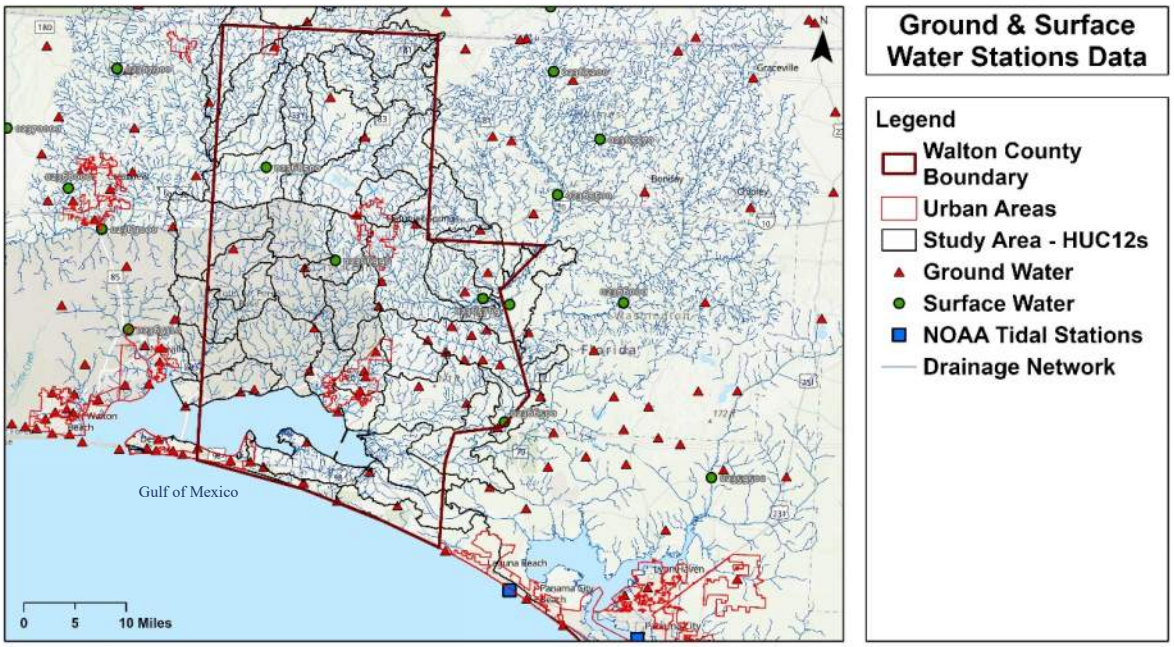

Figure 7. Ground & Surface Water Stations with drainage network for Walton County, processed by FAU.

1.1.3 Hydrologic Boundaries

The geographic area of the subject sub-watershed should be clearly defined to ensure that implementing the WMP will address all the major sources and causes of impairments and threats. Although there is no rigorous definition or delineation of this concept, one way to identify the geographic extent of the watershed master planning effort is to consult the United States Geological Survey (USGS) map of hydrologic units. A hydrologic unit is part of a watershed mapping classification system showing various areas of land that contribute surface water runoff to designated outlet points, such as lakes or stream segments. USGS designates drainage areas as sub-watersheds (including smaller drainages) numbered with 12-digit hydrologic unit codes (HUCs), nested within watersheds (10-digit HUCs). These are combined into larger drainage areas called subbasins (8 digits), basins (6 digits), and subregions (4 digits), which make up the large regional drainage basins (2 digits).

Region>>Subregion>>Basin>>Sub-basin>>Watershed>>Sub-watershed

The HUC 031402030501 has no major rivers and canals, but creeks and branches, include:

- Bruce Creek
- Mill Creek
- McCallum Branch
- Ward Branch
- Black Branch
- Panther Creek
- Indian Creek
- Bay Branch

Given that stream flow data are critical for estimating flooding, **Error! Reference source not found.** shows the historical streamflow during June 2022 to July 2023 for USGS 02366996. However, as there are only four surface water station within Walton County, it was necessary to use the nearest station to the sub-watershed 031402030501, which is USGS 02366996 Alaqua Creek Near Pleasant Ridge, FL.

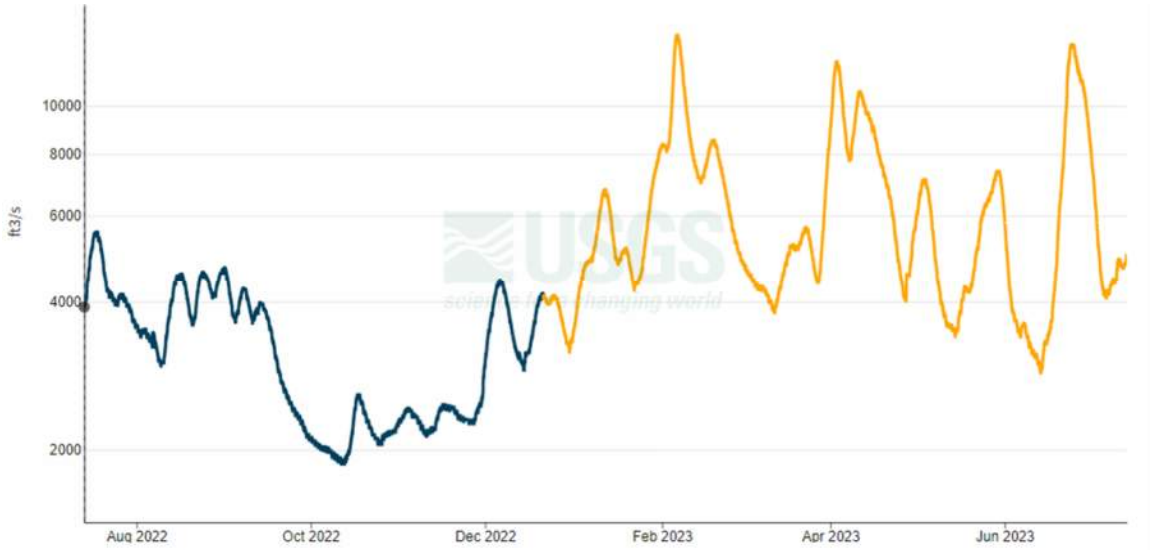

Figure 8. Average streamflow for Alaqua Creek Near Pleasant Ridge, FL (USGS 02366996 Surface-Water, June 2022 to July 2023).
Source: USGS Water Data Services (https://waterdata.usgs.gov/monitoring-location/02366996/#parameterCode=00065&period=P7D).

1.2 Groundwater

In this region of Florida, there is a direct interaction between groundwater and surface water. In addition to low land elevations and topographic relief, the groundwater and surface water are controlled by the canals, rivers, and tides. Since there is a limited number of groundwater monitoring stations, the strong relationship between groundwater and surface water was leveraged to develop a 99th- percentile surface of the water table elevation for mapping purposes. To establish

a common date for modeling, the recorded groundwater table elevations were sorted in ascending order to determine the 98th - 100th percentile date of occurrence in Excel®, following the procedure detailed in Romah (2011). This procedure was automated for this effort using a python code to process the groundwater data more efficiently. Outliers and anomalous groundwater levels in the database are initially identified (e.g. catastrophic storm events) and replaced by region-specific mean values based on observations available from the nearest well. Missing date-specific data are estimated using simple temporal interpolation based on observations available in time. If a station (or monitoring well) data contains large amounts of missing data, it is not used in the generation of the groundwater surface.

In Walton County, the average annual rainfall is abundant, reaching 65 inches at DeFuniak Springs. This rainfall predominantly infiltrates the sand-and-gravel aquifer and eventually seeps into streams or the underlying artesian Floridan aquifer. The county's two major aquifers are the sand-and-gravel aquifer and the Floridan aquifer. While the sand-and-gravel aquifer provides water for rural domestic use and plays a crucial role in water storage and streamflow maintenance, it also serves as a recharge source for the Floridan aquifer. Water from the sand-and-gravel aquifer contains varying levels of dissolved solids, pH, and iron content. The Floridan aquifer, being the primary water supply source, underlies the entire county and yields around 500 to 1,000 gallons per minute from wells, except along the Gulf Coast where the permeability is lower. Recharged by leakage from the sand-and-gravel aquifer, the Floridan aquifer's movement is predominantly southward away from the potentiometric high in northwestern Walton County. It discharges through springs, seeps along the Choctawhatchee River, and by wells. In southern Alabama, the Floridan aquifer is directly recharged by rainfall when it is exposed or close to the land surface. (Bureau of Ecology, 1974).

Once a common time period is determined across the majority of shallow groundwater wells, canal data can be gathered for that common date (and two days prior, in the event the canals were deliberately lowered). Data was obtained from the NWFWMD and processed by FAU at cwr3.fau.edu. Between stations, an ArcGIS tool permits a line to be drawn to replicate the rivers and streams to establish points for a gradient between stations. The same is true for the ocean, but it is a constant head boundary. The topography and points where streams join form boundary conditions for the screening tool on the edges of the basin and affect localized groundwater. The tide issue is resolved by using the common date for high tide.

Error! Reference source not found. shows the drainage network of HUC 031402030501 and points out the location of the ground water station in the surroundings. A groundwater-surface layer for the HUC 031402030501 sub-watershed was created using several datasets including water level data from USGS and NWFWMD and groundwater elevation contour maps. The datasets were used to generate a raster surface of the groundwater elevation (**Error! Reference source not found.**).

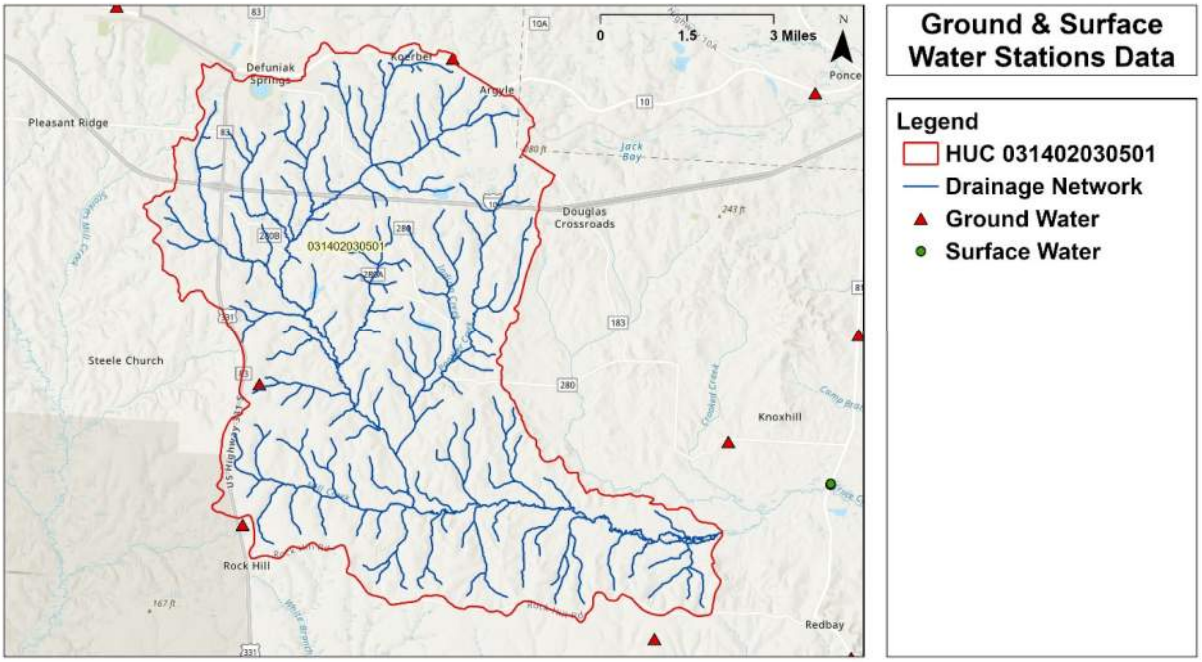

Figure 9. Ground and Surface Water Stations in the HUC 031402030501 sub-watershed, processed by FAU.

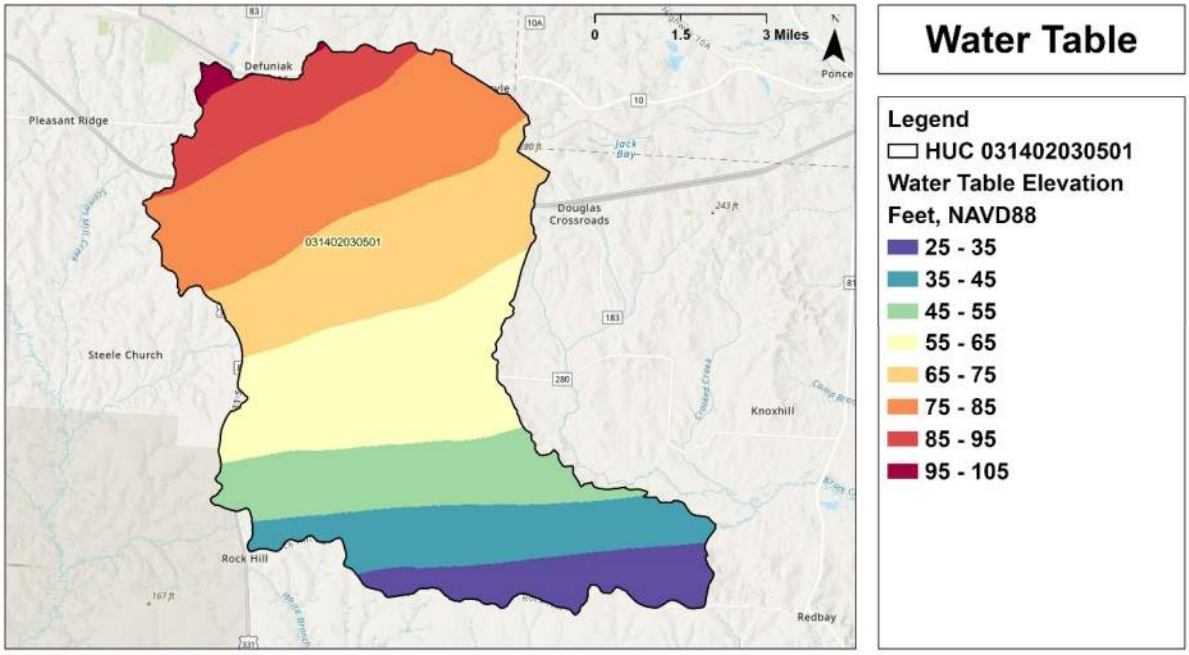

Figure 10. Elevation of the top of the surface groundwater layer for the HUC 031402030501 sub-watershed, created by multiple linear regression analysis – elevation NAVD88, processed by FAU.

1.3 Surface Water/Tides

Historically, surface water and tides have been an important factor in determining how much freshwater is delivered, how fast this water enters wetlands and estuaries, and the quality of that water. Evapotranspiration and rainfall do not coincide in the study area, which makes water supply planning difficult. **Error! Reference source not found.** shows the observed rainfall over Walton County for every month between 1900 and 2023 - each rectangle is a month and each column is a year. The 12-month total precipitation decreased 7.5 inches from May 1900 to April 2023. From May 1900 to April 2023, the average 12-month total precipitation was 60.5 inches, for the entire county.

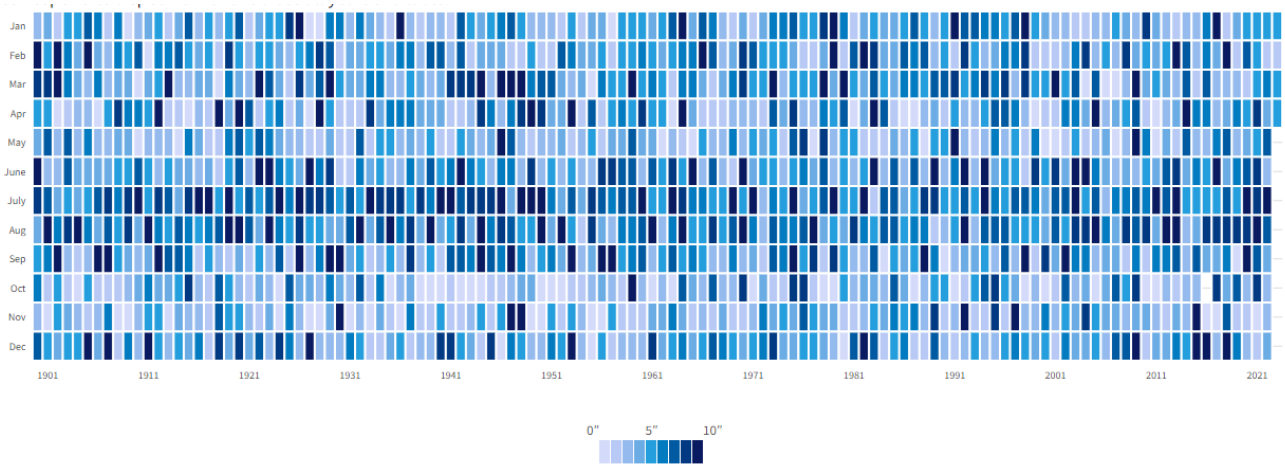

Figure 11. Monthly precipitation in Walton County, FL.
Source: National Centers for Environmental Information
(https://usafacts.org/issues/climate/state/florida/county/walton-county/#precipitation/).

While the topography (Section 1.1) and native soil (Section 1.4) create an environment that is highly permeable and capable of infiltrating significant percolation into the soil, changes in land use and land cover have resulted in water falling on impervious areas, where the water collects in pools or runs off rapidly, in direct contrast to the natural condition. This runoff flowing over impermeable regions can lead to larger scale flooding.

Tidal data can be gathered from NOAA tidal gages and other gages monitored by local governments. The location of tide gages is important to ensure they accurately depict tides, as opposed to inland waters. To set a boundary for the coastal areas, the high tide on the common date from 12/03/2018 to 12/10/2018 was selected. **Error! Reference source not found.** shows the two closest tide stations to Walton County. Since there is no NOAA tide station in Walton County, the Panama City Beach station (8729210) was used.

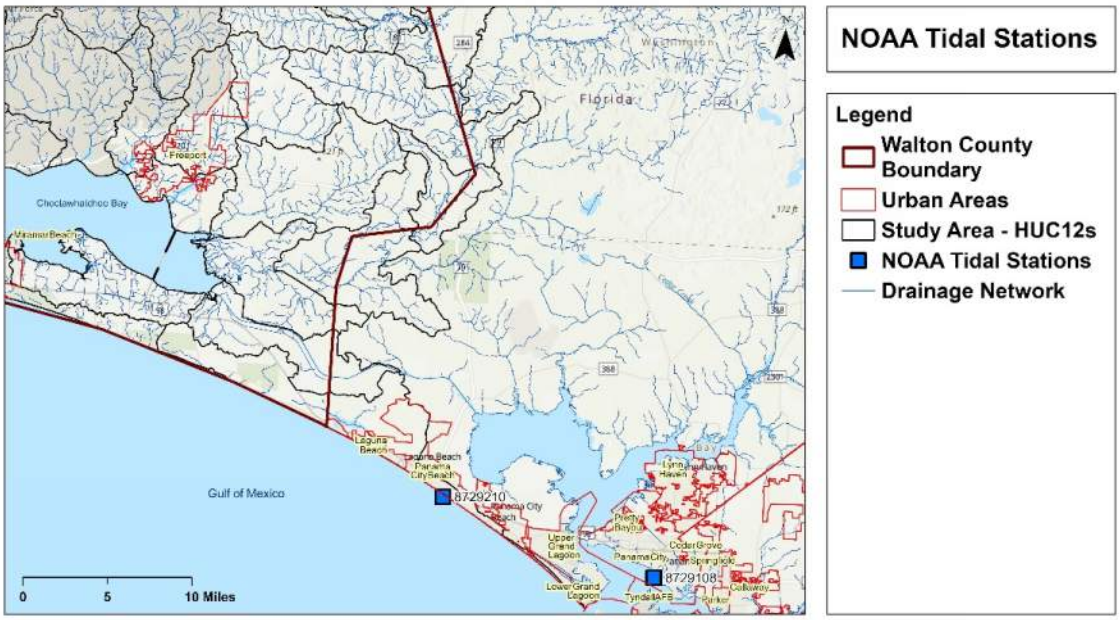

Figure 12. Locations of Florida tidal stations maintained by NOAA near to Walton County, processed by FAU.

1.4 Soils

Soil can store water if there is adequate distance between the topographic surface and the groundwater, and the soil types are capable of absorbing the water. Soil storage capacity is the volume of soil pores in the unsaturated zone that is available to store infiltrated stormwater (Gregory et al., 1998). Throughout Florida, it is common to have large volume storm events that fill the voids in the unsaturated zone as shown in **Error! Reference source not found.**.

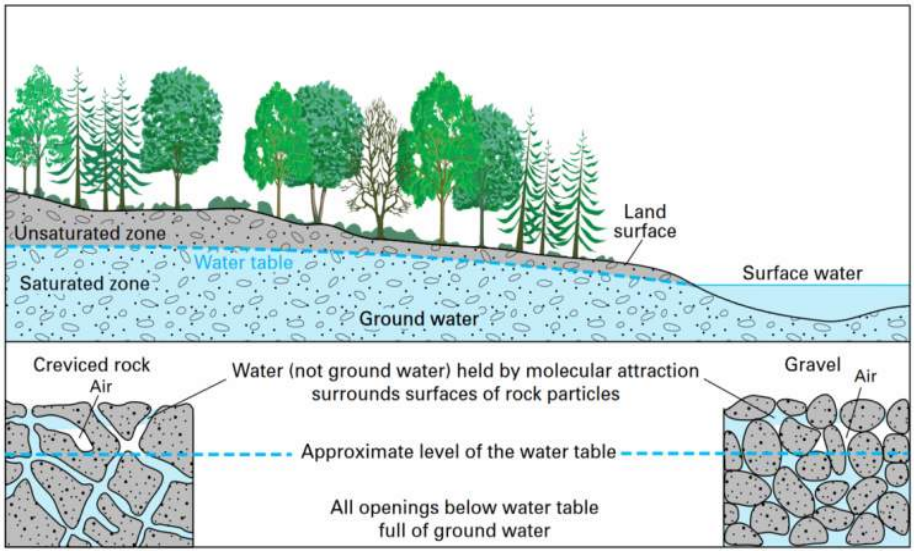

Figure 13. Zones where underground water exists.
Source: USGS, 2020.

The unsaturated zone is the portion of the subsurface above the water table that contains soil/rock and air and water in its pores as shown in **Error! Reference source not found.**. This zone affects the rate at which the aquifer is recharged by controlling water movement from the surface of the land downward towards the aquifer. During rain events, the soil voids fill up quickly resulting in the water table rising to the surface, and the surplus rainfall becomes runoff.

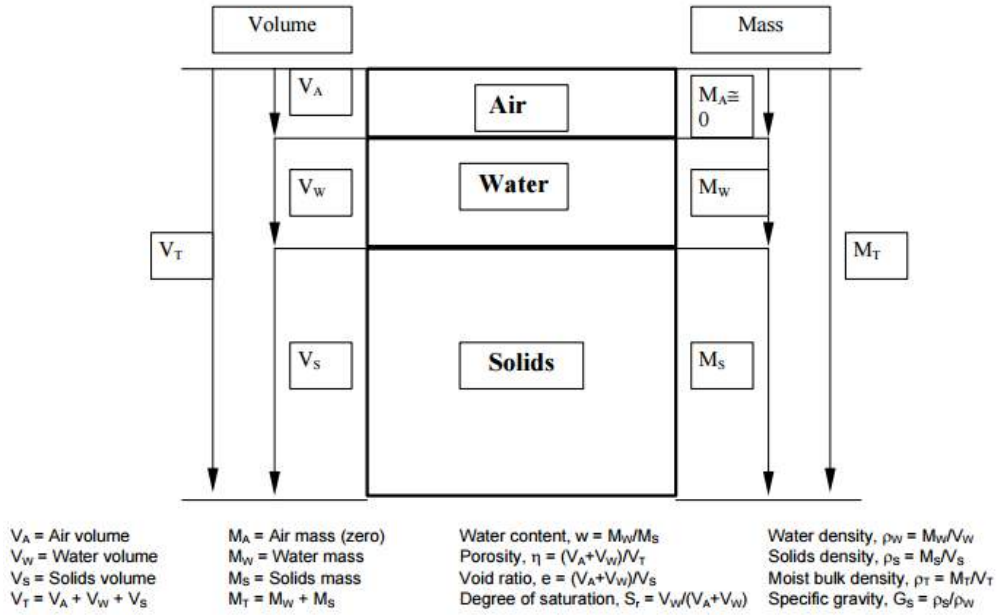

Figure 14. Saturated zone soil phase diagram and definitions.
Source: Gregory et al., 1998.

Soil data is available from the United States Department of Agriculture (USDA) or other agencies in the form of maps that can be incorporated as a GIS layer. The Gridded SSURGO (gSSURGO) dataset from USDA is chosen. This dataset is similar to the standard product from USDA Natural Resources Conservation Service (NRCS) Soil Survey Geographic (SSURGO) database, but is in the Environmental Systems Research Institute, Inc. (ESRI®) file geodatabase format. A file geodatabase allows for statewide or even Conterminous United States (CONUS) tiling of data. The gSSURGO dataset contains all of the original soil attribute tables in SSURGO. All spatial data are stored within the geodatabase instead of externally as separate shape files. Both SSURGO and gSSURGO are considered products of the National Cooperative Soil Survey (NCSS). Figure 15 shows the unsaturated zone found by the difference between the groundwater elevation layer and surface topography.

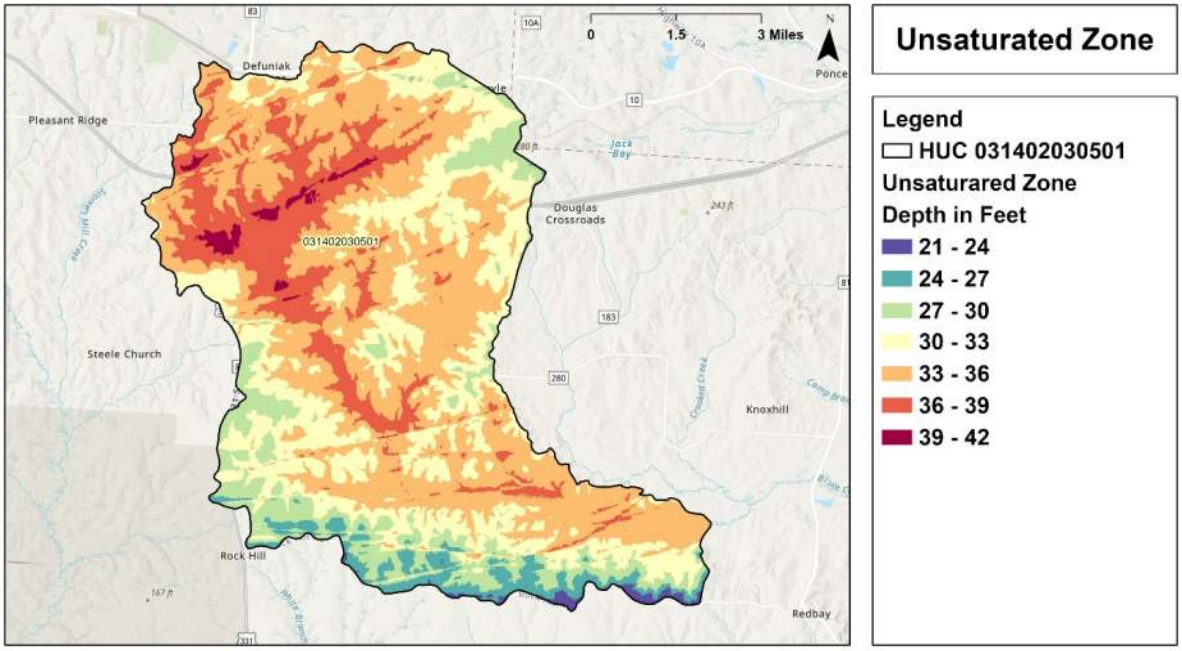

Figure 15. Unsaturated zone map for HUC 031402030501, processed by FAU.

The available water storage from USDA derived for the soil layer (0-150 cm or 0-5 ft) statewide is shown in **Error! Reference source not found.**, which covers most of Florida with a spatial resolution of 10 m. The unit is in cm. As a result of applying this layer to the study area (**Error! Reference source not found.**), the estimated soil storage capacity can be illustrated. A significant portion of the basin demonstrates a moderately favorable soil storage capacity, falling within the range of 27 to 39 feet of remaining capacity.

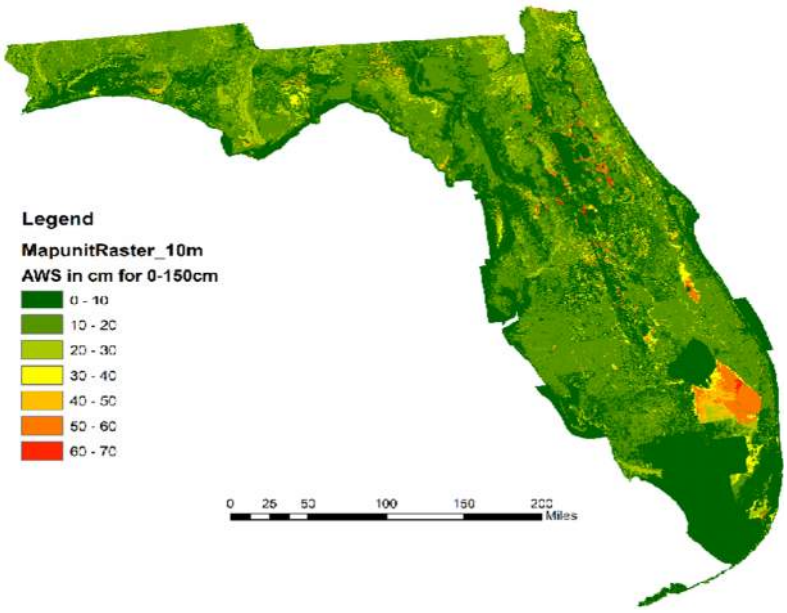

Figure 16. Available water storage derived from the gSSURGO soil database for all of Florida, as processed by FAU.

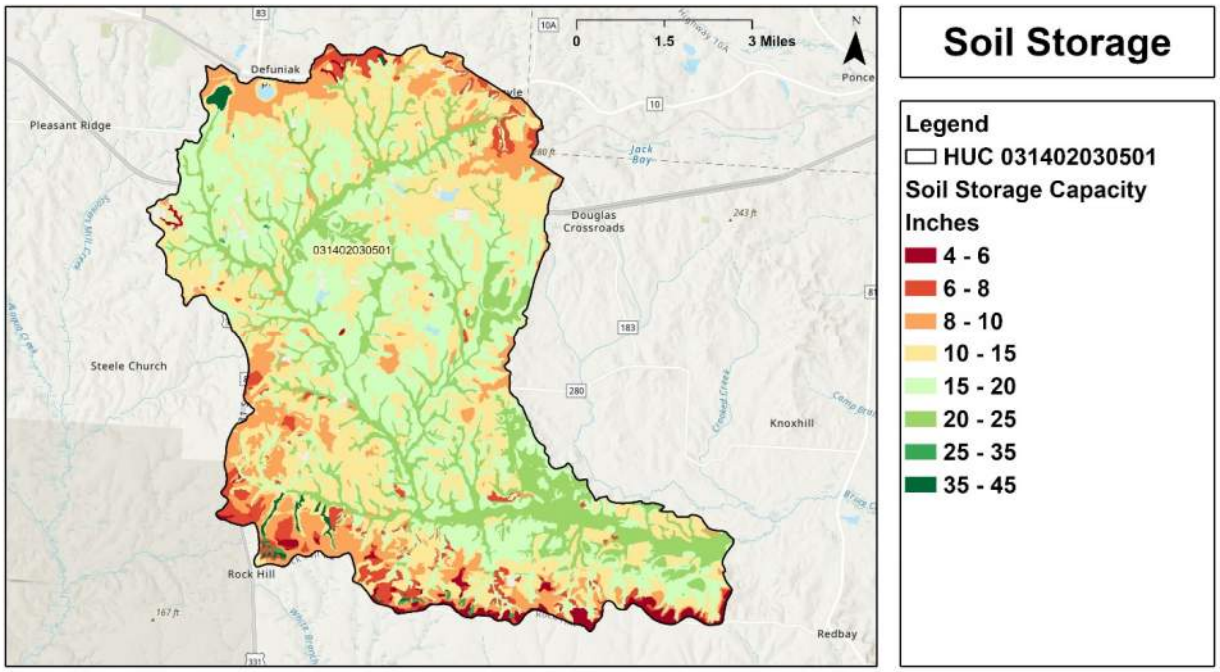

Figure 17. Water storage capacity of soil for the HUC 031402030501, processed by FAU.

Lastly, **Error! Reference source not found.** shows the water holding capacity for the basin, which refers to the capacity of a particular soil texture to retain water against the force of gravity.

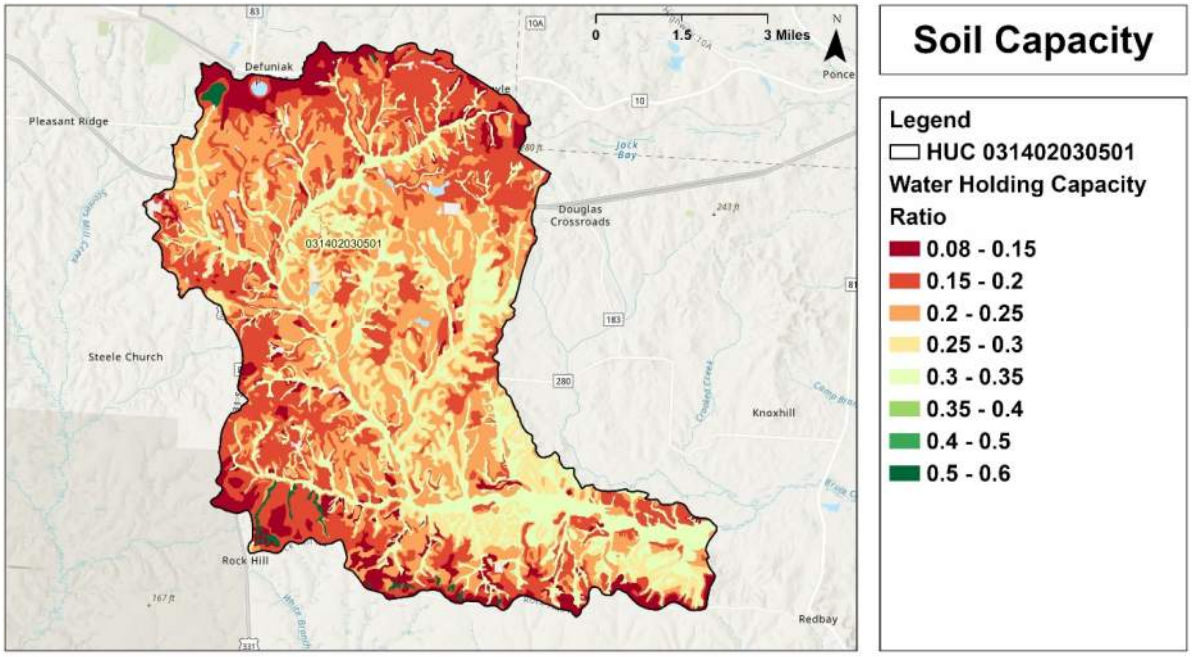

Figure 18. Water Holding Capacity (ratio) for the HUC 031402030501, processed by FAU.

1.5 Land Cover

The USGS produces the NLCD of nationwide data on land cover at a 30-m resolution with a 16-class legend based on a modified Anderson Level II classification system. NLCD is coordinated through the 10-member Multi-Resolution Land Characteristics Consortium (MRLC) to provide digital land cover information nationwide. For the conterminous United States, NLCD 2016 contains 28 different land cover products characterizing land cover and land cover change across 7 epochs from 2001-2016, urban imperviousness and urban imperviousness change across 4 epochs from 2001-2016, tree canopy and tree canopy change across 2 epochs from 2011-2016 and western U.S. shrub and grassland areas for 2016 (**Error! Reference source not found.**).

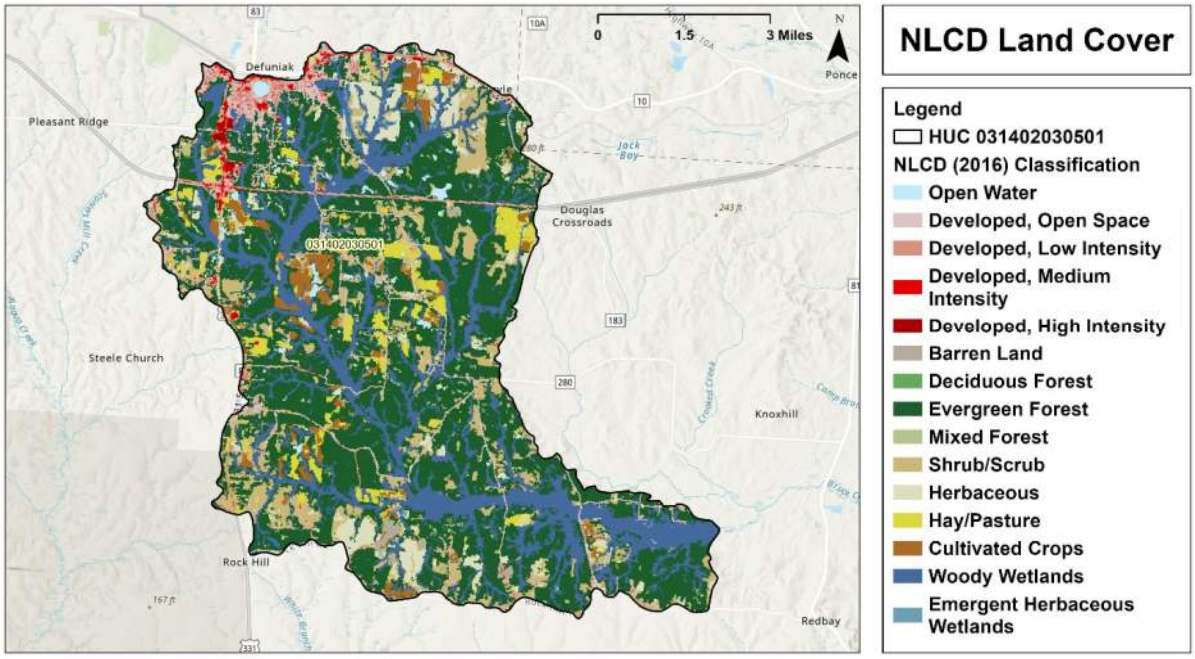

Figure 19. Land use in the HUC 031402030501 (from the NLCD 2016 database), processed by FAU.

The dataset is derived from the Florida Land Use Cover Classification System (FLUCCS), which is digitized by photo-interpretation on county-based aerial photography with varying resolution in the range of 4 in - 2 ft pixel. The NLCD2016 has a 30-meter resolution derived from Landsat imagery. Hence, the NLCD maps appear much coarser and pixelated compared to the 2023 Florida Geographic Data Library (FGDL) (https://fgdl.org/fgdlmap/) maps. A view of the latter is provided in **Error! Reference source not found.**. The future land use maps need to be used for the final land cover, as adjusted for future stormwater improvements set by regulatory standards.

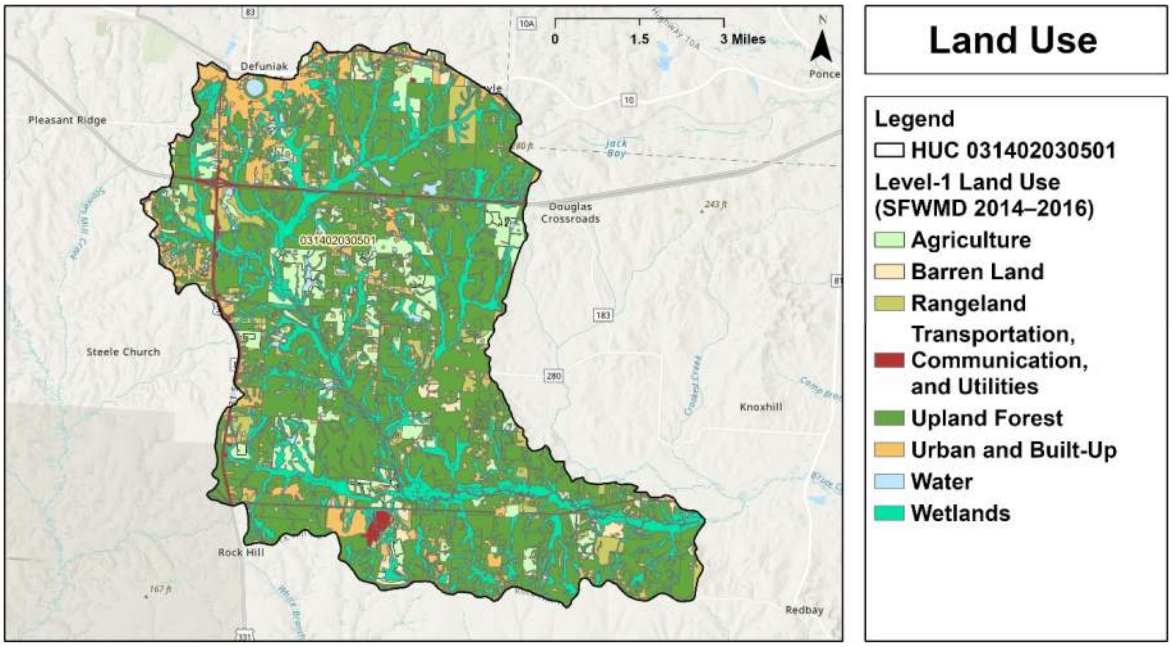

Figure 20. Land use in the HUC 031402030501 (from the 2023 Florida Geographic Data Library (FGDL)), processed by FAU.

In the HUC 031402030501 sub-watershed, the predominant land cover is upland forest, accounting for 52.64% of the area. Wetlands comes in second at 16.53%, followed by Urban and Built-Up at 8.11%, and Agriculture at 7.92%. Unlike most HUCs in the County, the basis presents a moderate portion of developed land once the basin takes a small portion of the city DeFuniak Springs. The percentage of area by land use type is as shown in **Error! Reference source not found.**. **Error! Reference source not found.** shows the roughness of the surface.

Table 3. Land use for HUC 031402030501 subwatershed (2023 Florida Geographic Data Library (FGDL)).

Level 1 Land Use Land Cover Type	Area (Acres)	Percentage of Total
Agriculture	3468.64	7.92%
Barren Land	479.98	1.10%
Rangeland	2022.03	4.62%
Transportation, Communication, and Utilities	3389.03	7.74%
Upland Forest	23045.26	52.64%
Urban and Built-Up	3551.06	8.11%
Water	587.23	1.34%
Wetlands	7234.34	16.53%
Grand Total:	**43777.58**	**100.00%**

Table 4. Roughness and CN Values for Each Land Use Code.

DOR Code	Use	Impervious %	Roughness
0	Vacant	0	0.4
1	Single Family	29	0.25
2	Mobile homes	21	0.05
4	Condos	60	0.05
7	Vacant –to be developed	0	0.4
8	Multifamily	60	0.05
TH 101	Townhomes	91	0.025
94	Road Right-of-Ways	50	0.08
	Open water	100	n/a
All others	Commercial, etc.	50	0.07

1.6 Precipitation

Rainfall used in the screening tool is based on the SFWMD 3-day 25-year storm, but can be modified for any rainfall event using the accumulated rainfall table obtained from NOAA Atlas 14 Point Precipitation Frequency Estimates (https://hdsc.nws.noaa.gov/hdsc/pfds/pfds_map_cont.html). Figure 21 shows the 3-day 25-year rainfall map based on the NOAA Atlas 14 dataset for the whole state. **Error! Reference source not found.** to **Error! Reference source not found.** rainfall 1-day 100-year, 1-day 10-year, and 1-day 5-year storm event scenarios, in inches.

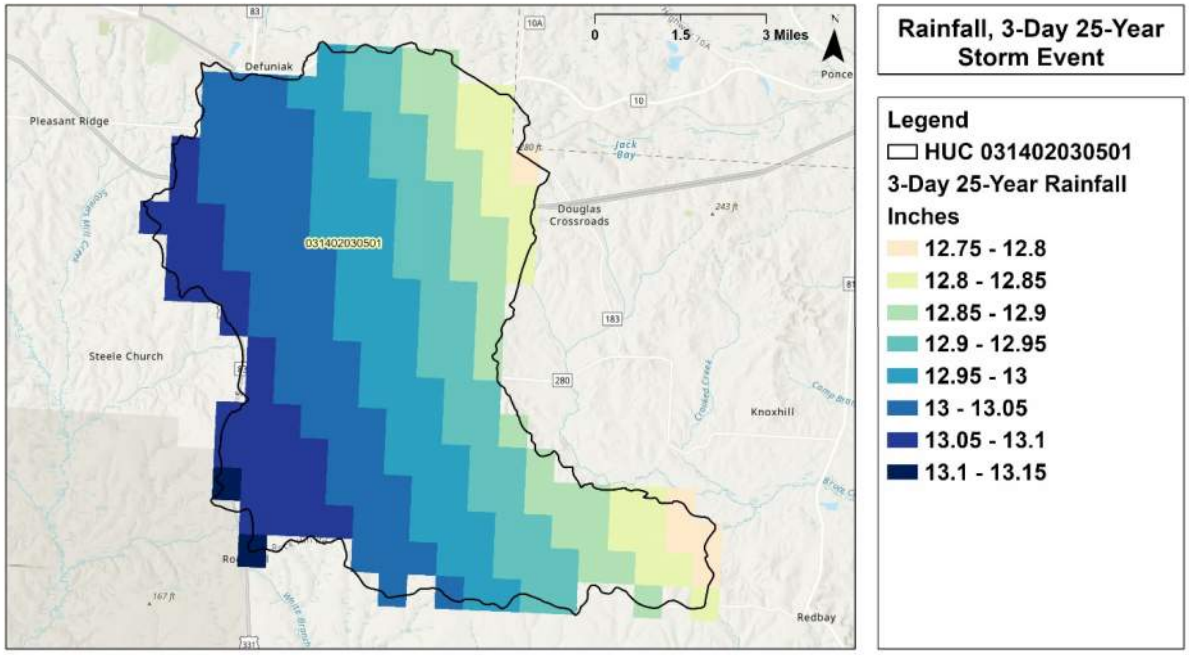

Figure 21. Rainfall distribution map across HUC 031402030501 sub-watershed, for 3-day 25-year storm event, processed by FAU.

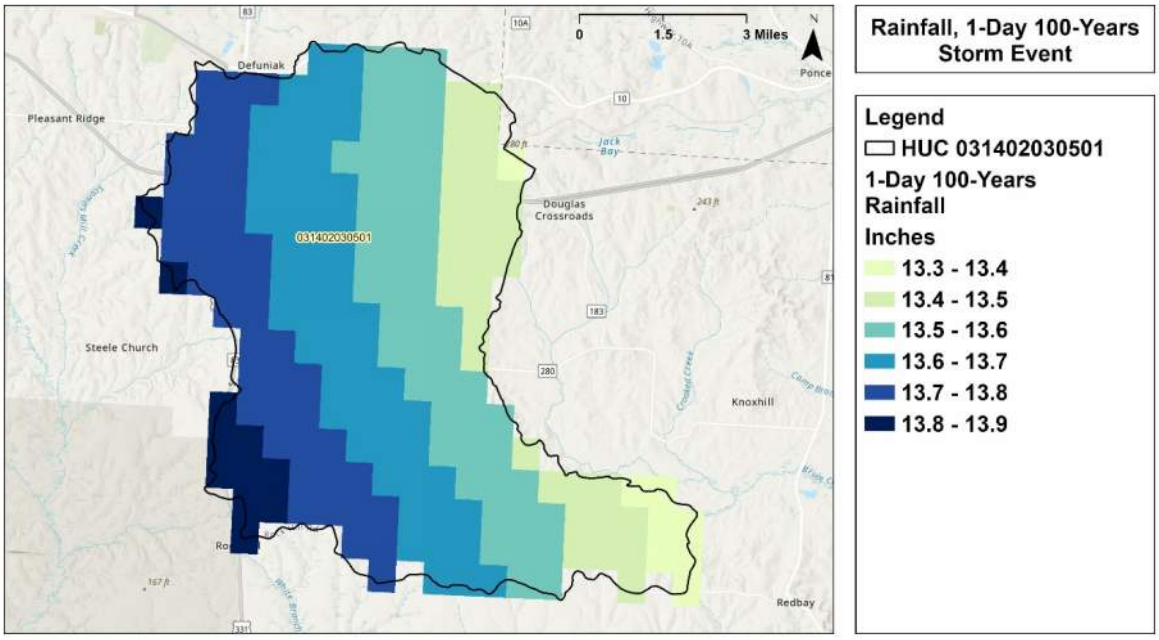

Figure 22. Rainfall distribution map across HUC 031402030501 sub-watershed, for 1-day 100-year storm event, processed by FAU.

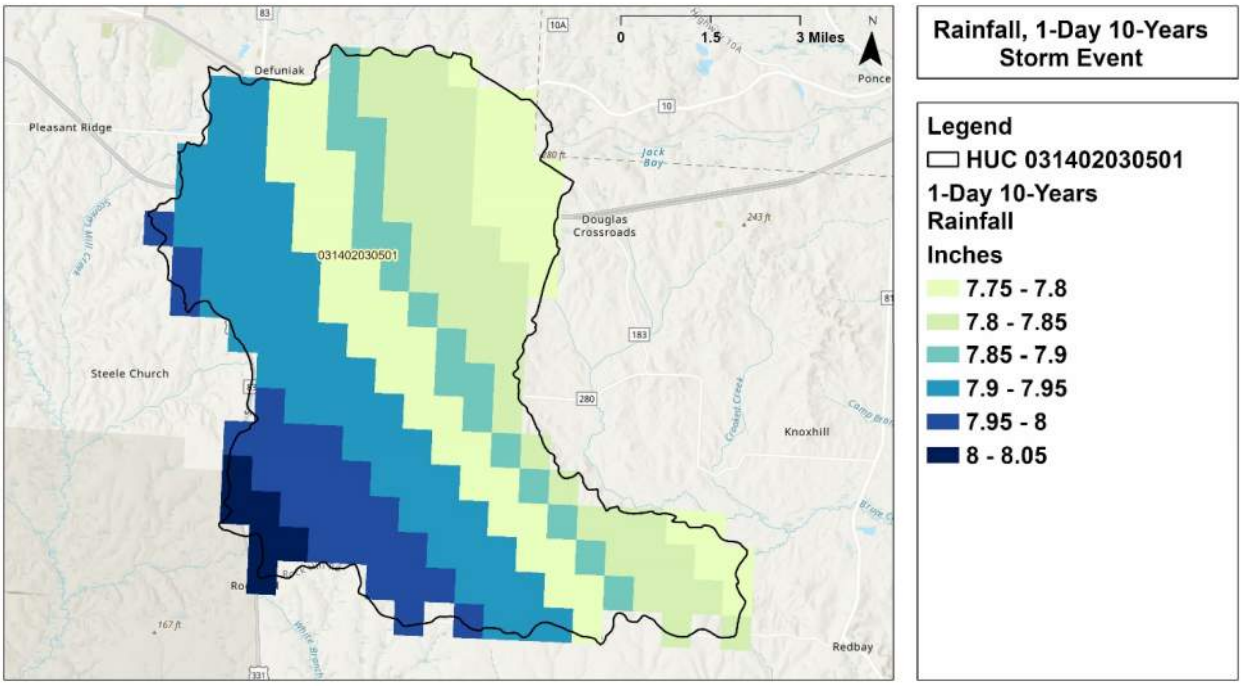

Figure 23. Rainfall distribution map across HUC 031402030501 sub-watershed, for 1-day 10-year storm event, processed by FAU.

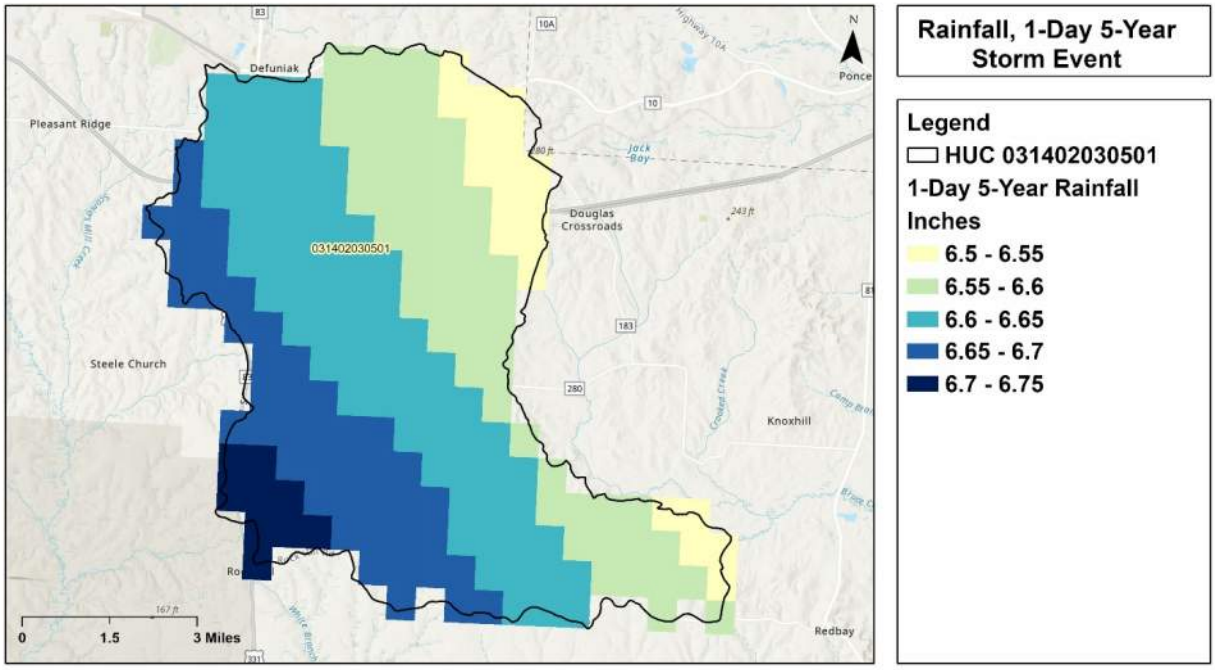

Figure 24. Rainfall distribution map across HUC 031402030501 sub-watershed, for 1-day 5-year storm event, processed by FAU.

1.7 Open Space

Open space is defined as areas that are exempted from development. Generally, this means one or more of the following qualifiers exist:

1. Land that is valuable for recreation, forestry, fishing, or conservation of wildlife or natural resources
2. Land that is a prime natural feature of the state's landscape, such as a shoreline or ridgeline
3. Land that is habitat for native plant or animal species listed as threatened, endangered, or of special concern
4. Land that is a relatively undisturbed example of an uncommon native ecological community
5. Land that is important for enhancing and conserving the water quality of lakes, rivers, and coastal water
6. Land that is valuable for preserving local agricultural heritage
7. Proximity to urban areas or areas with open space deficiencies and underserved populations
8. Vulnerability of land to development
9. Stewardship needs and management constraints
10. Preservation of forest land and water bodies that naturally absorb significant amounts of carbon dioxide

Permanent protection of sensitive areas can provide critical water quality protection and can be achieved through partnerships with landowners, municipalities, land trusts and state agencies. There is limited land in the study area that has been protected via acquisition by federal, state or local agencies, has conservation easements or is designated as wetlands or areas of critical concern. Agricultural land and other land cover will come from the land cover map (in Section 2.5). Added to this will be the water bodies discussed in Section 2.9, which serve a related condition to open space.

1.8 Impervious Areas

Impervious areas do not permit the infiltration of rainfall to groundwater, and because the water cannot infiltrate, it runs off faster. Faster runoff means that flows to water bodies and storm sewers occur faster and with higher peaks. The result is a disruption of the natural and potentially the planned hydrology. Impervious areas include pavement, buildings, and other areas that reduce runoff capacity. In other words, developed areas have much higher imperviousness than open spaces that are natural or agricultural.

The NLCD provides nationwide data on land cover and land cover change at a 30-m resolution with a 16-class legend based on a modified Anderson Level II classification system. Systematically

aligned over time, the database offers the ability to understand both current and historical land cover and land cover change to enable assessment of trends. Using the NLCD 2016 dataset, a layer was created by using only three categories out of the 13 to identify impervious areas such as primary roads in urban areas, secondary roads in urban areas, and tertiary roads in urban areas. The new layer was then converted to match the 3-meter spatial resolution from the DEM and the standard State Plane Coordinate system. **Error! Reference source not found.** shows the impervious areas derived from the NLCD 2016 as updated by the future land use map.

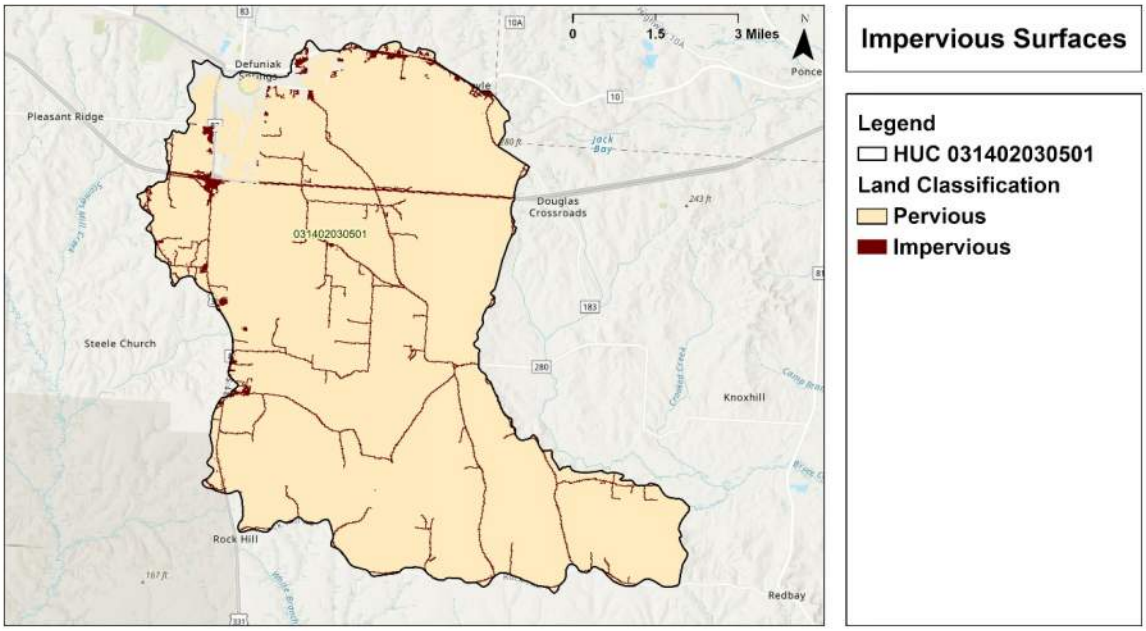

Figure 25. Impervious area map for the HUC 031402030501 sub-watershed, processed by FAU.

1.9 Water bodies

Water bodies were defined in the statewide land use land cover dataset to set soil water holding capacity to zero in model simulations (**Error! Reference source not found.**). Note that tiny water bodies may be missing from the maps. Soils were discussed previously in Section 2.4.

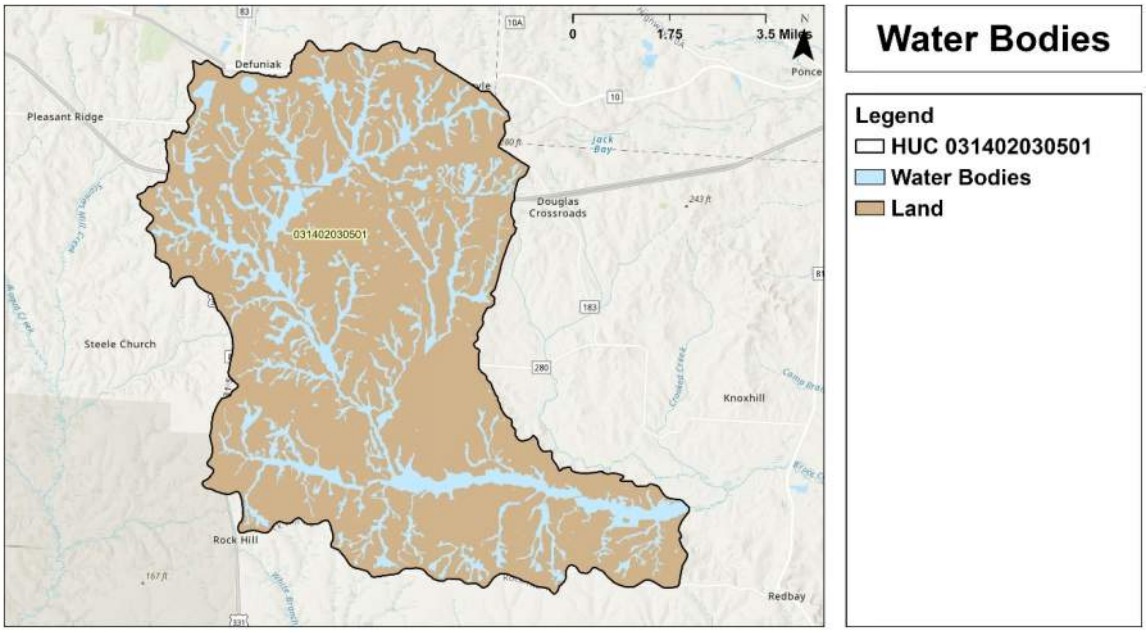

Figure 26. Water bodies map for the HUC 031402030501 sub-watershed, processed by FAU.

1.10. Natural Resources

Understanding the study area's natural resources is critical to identifying potential sources of water quality degradation and areas to designate for conservation, protection, and restoration. One possible goal of watershed master planning is to protect terrestrial wildlife, aquatic habitat, and buffer zones. USGS maintains important sources of information on physical and geographical features as well as soil and mineral resources, surface and ground water resources, topographic maps, and water quality monitoring data. The USDA's Natural Resources Inventory (NRI) (www.nrcs.usda.gov/technical/NRI) is a survey of information on natural resources on non-federal land in the United States that captures data on land cover and land use, soil erosion, prime farmland soils, wetlands, habitat diversity, erosion, conservation practices, and related items. Since 2001, the NRI has been updated continually with annual releases of NRI data from all 50 states. The information provided can be used for addressing agricultural and environmental issues down to the county or cataloging unit level. Therefore, this data can be used to determine erosion and site-specific soil characteristics for certain land uses such as croplands, pasturelands, forestlands, etc., but the data is typically provided as inventories, not GIS layers.

1.11 Demographics

Demographics data is important for determining several key indicators for watershed master planning such as the ability to pay for improvements, social justice issues, land acquisition costs, property/land use, and communication strategies. The US Census has databases at the census tract

level. Based on the census data for the study area, **Error! Reference source not found.** outlines population and racial composition demographics.

Table 5. Demographics and Housing Characteristics of Cities and Towns in Walton County.

Demographic Parameter	**Miramar Beach**	**Freeport**	**DeFuniak Springs, City**	**Paxton**	**Rosemary Beach**	**Santa Rosa Beach***	**Walton County**

*It includes the communities of Point Washington to the East and a 15-mile stretch of the Emerald Coast from the east side of Miramar Beach to the west side of Seagrove Beach and the beach communities along 30A, including Grayton Beach and Seaside.

** Census Designated Place.

1.12 Stormwater Infrastructure Inventory

Local community stormwater systems consist of drainage ditches, storm sewers, retention ponds and other facilities constructed to store runoff or carry it to a receiving stream, lake, ocean, or other

waterbody. Other man-made features include yards and swales that collect runoff and direct it to the sewers and ditches. When most of these systems were built, they were typically designed to handle the amount of water expected during a 10-year storm. Larger storms overload them, and the resulting backed-up sewers and overloaded ditches produce shallow flooding. Another urban drainage problem occurs in the areas protected by levees. Being in floodplains, they are flat and do not drain naturally, especially when a levee blocks the flow to the river. To drain these areas, channels have been built and pumps installed to mechanically move the water past the levee. Often, these man-made systems do not have the capacity to handle heavy rains or intense storms.

Another challenge with stormwater infrastructure is related to recordkeeping. It is not uncommon for stormwater data to be incomplete in most jurisdictions and completely lacking in others. Quality of data differs from jurisdiction to jurisdiction; some are in GIS formats, while others are paper maps or as-builts that represent the infrastructure at a macroscale level. The condition of the assets may be lacking, and the maintenance history may not be available either. Stormwater assets may have been installed with no records, especially in rural areas, farm fields, and private property.

Walton County passed Ordinance No. 2008-06 that prohibits unauthorized discharges into storm drains or ditch systems. In addition, the Public Works Division is currently running a continuous public awareness campaign aimed at encouraging the adoption of best management practices (BMPs) for managing stormwater runoff. This initiative targets both the business community and the residents of Walton County.

To address the issue of flooding, Walton County has implemented several measures along the years, such as:

- Drainage Systems: The county has invested in the development and maintenance of drainage systems, including ditches, canals, and retention ponds, to manage stormwater runoff and reduce flood risk.
- Floodplain Management: Walton County has adopted floodplain management regulations and participates in the National Flood Insurance Program (NFIP) to encourage responsible development in flood-prone areas.
- Elevation Standards: New construction projects within flood zones are required to adhere to specific elevation standards to minimize potential flood damage.
- Emergency Response: The county has established emergency response plans to assist residents during flood events, including evacuation procedures and the provision of emergency shelters.

Key stormwater assets for the HUC and Walton County are indicated in **Error! Reference source not found.** and **Error! Reference source not found.**, respectively. Stormwater structures and management processes in the county consist of stormwater outfall, water wells, weir, pollutant

control boxes, inlets catch basins, pipes culverts, ditch conveyance swales, structures, pipes and open conveyance.

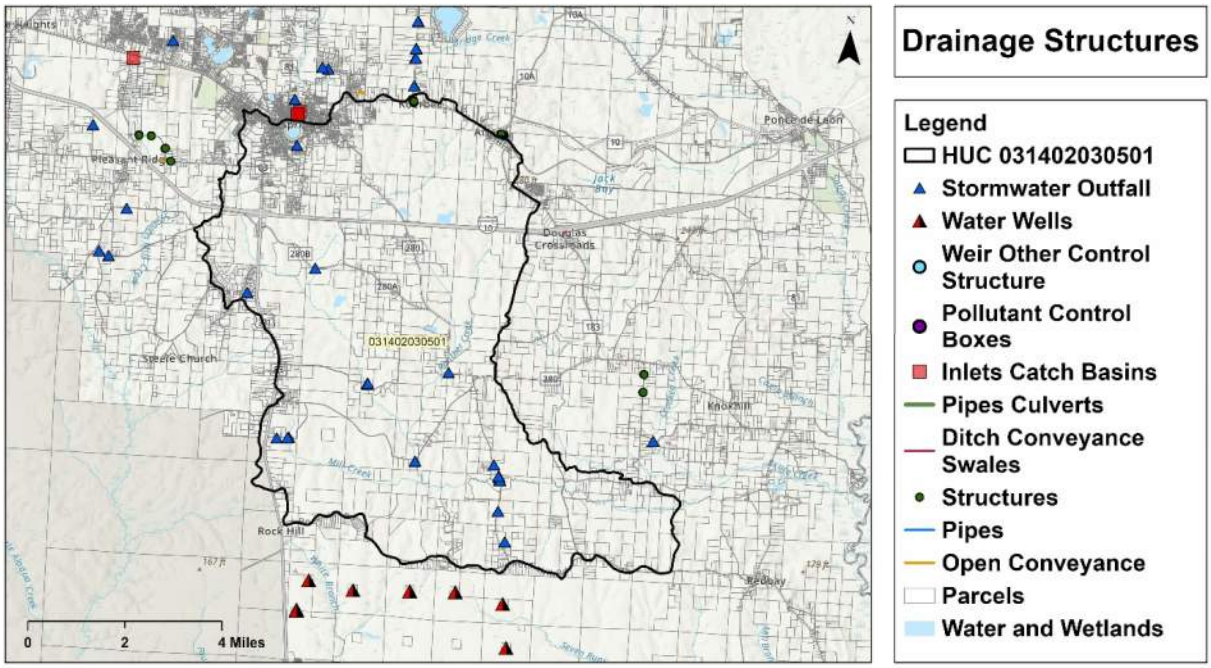

Figure 27. Stormwater Infrastructure for the HUC 031402030501. Processed by FAU.

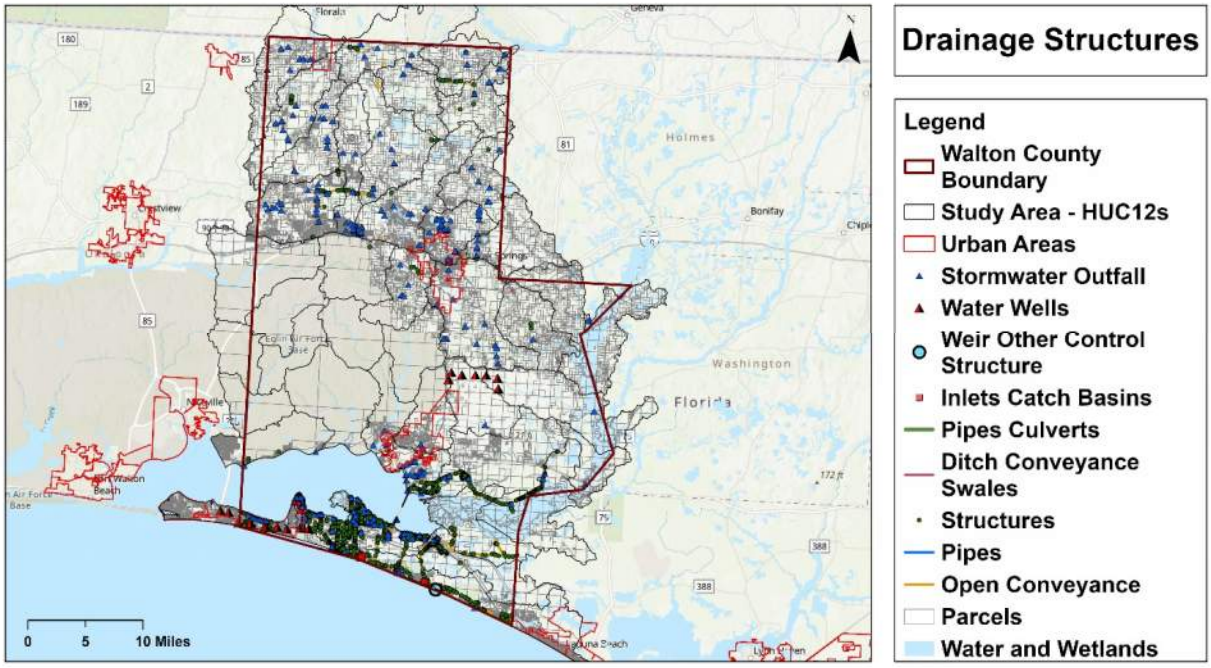

Figure 28.Stormwater Infrastructure for Walton County. Processed by FAU.

Although nature-based infrastructure might be installed, it is not certain. The stormwater system must maintain compliance with the stormwater regulations, which requires record-keeping, policy development, inspections and maintenance. The goals of such stormwater management may include:

- Best landscape practice;
- Control car washing contribution to pollution;
- Enforce the Stormwater Pollution Prevention Plan (SWPPP) by site evaluation, assessment, erosion and sediment controls, preventive maintenance, certification and inspection reporting for construction sites and city planning;
- Implement a hazardous material elimination system;
- Eliminate illicit dumping;
- Proactive and reactive catch basin inspections and maintenance;
- Street sweeping to control debris;
- Maintain swales to help prevent stormwater pollution flooding.

1.13 Data Gaps

FAU has developed comprehensive databases to address the information needed for the vulnerability assessment. These are included in **Error! Reference source not found.**. The data can be used to model the impacts of flood routing during the storm of interest. As a result, the modeling pieces (discussed in Chapter 2) will include the following:

- Flood response model results (Cascade 2001)
- Flood risk/hazard mapping
- Vulnerability assessments to identify areas of concern for future repetitive losses

There is only one data gap for the area – existing stormwater infrastructure records are incomplete. However, for the purposes of this plan, this data gap does not limit the findings as there are two scales: 1) the sub-watershed level and 2) community hotspots. A neighborhood level vulnerability assessment will require the local infrastructure inventory.

Table 6. List of datasets collected by FAU as of List of datasets collected by FAU for the project (12/20/2020)

Data Category	Dataset Name	Original Source	Spatial Coverage/ Resolution	Temporal Coverage/ Resolution	Link to the Dataset on our Server (physical location)	Dataset size and Format	Native or FAU Processed dataset
Topography	USGS_NED	USGS	Part of Florida, raster image in 1 m	Created by USGS in 2016	\\engsynws01.eng.fau.edu\Project_mastercopy\Datasets\LiDAR_DEM\DEM_1m	3.28G bytes, raster images	Native

2.0 ASSESSMENT OF VULNERABLE AREAS

Defining flood risk due to compounding hydrographic influences is the central concern of this WMP. Modeling and assessment of vulnerability focused on the combination of a high-water table, heavy rains, and impervious conditions that can lead to localized nuisance flooding events. Through a previous survey with local officials, the number of days of continuous nuisance flooding that the public will tolerate before that flooding is considered destructive is about 4 days (E Science 2014).

For a large study area, small parts may actually be at risk. The point is to identify where further study might be needed. A screening tool accomplishes this goal applied to the sub-watershed scale to designate areas that are susceptible to periodic flooding events. Utilizing the information collected and analyzed in Chapters 1 and 2, and comparing to data in Chapter 3, vulnerability can be identified.

2.1 Historical and Existing Challenges

Walton County has faced various historical and existing challenges as well as natural hazards over the years. Some of these include:

- Hurricane and Tropical Storms: being situated along the Gulf Coast, Walton County is vulnerable to hurricanes and tropical storms, which can lead to damage to the built and natural environment, as well as poses risks to human and wild life.
- Coastal Erosion: The county's coastline is subject to erosion due to natural processes and human activities. Erosion can lead to the loss of beaches and threaten coastal structures and properties.
- Flooding: heavy rainfall, storm surges from hurricanes, and other factors can cause localized flooding, particularly in low-lying areas. Flood events can disrupt daily life, damage property, and impact transportation.
- Water Quality and Quantity: as in many coastal areas, managing water quality and maintaining an adequate water supply are ongoing challenges. Pollution from stormwater runoff and other sources can affect water quality, and groundwater resources need to be carefully managed to sustain the growing population.
- Wetland Loss: The county's wetlands face the threat of degradation and loss due to urban development and other human activities. Protecting these essential ecosystems is vital for maintaining biodiversity and mitigating flood risks.
- Urbanization and Development: Balancing the demand for development and growth with the preservation of natural habitats and resources is a persistent challenge. Unplanned

urbanization can lead to habitat destruction, increased runoff, and exacerbate flooding risks.

- Land Use and Zoning: Proper land use planning and zoning are essential to address issues related to population growth, infrastructure development, and natural hazard mitigation. Ensuring responsible development practices can help minimize risks.
- Invasive Species: Like many regions, Walton County faces the threat of invasive plant and animal species. These invasive species can disrupt local ecosystems, negatively impacting native flora and fauna.
- Sea-Level Rise: With rising sea levels due to climate change, coastal communities like Walton County's coastal areas are at greater risk of inundation and storm surges during extreme weather events.

The fast growth of the population and urban development in the coastal areas of the county exacerbates effort to protect open space for land percolation of water. While regulations are in place to reduce the influx of stormwater, the challenges will continue with development.

2.1.1 Existing Management Efforts in the Watershed

The county is under Northwest Florida Management District (NWFMWD) jurisdiction, which covers the Florida Panhandle region. The NWFMWD is responsible for managing and protecting water resources in its designated regions, which includes issues related to water supply, water quality, flood control, and natural resource conservation. Local governments have local stormwater utility infrastructure and planning/policy tools to reduce future flood potential. Most of the major projects to date have been focused on addressing the water quality issues and flooding due to extreme rainfall.

2.1.2 Critical Target Areas Identification

By modeling the HUC 031401030501 sub-watershed flood response to a series of rainfall events and sea levels (plus king tides), and further classifying flood risk as the probability of inundation, it is possible to identify critical target areas. These areas are particularly vulnerable to flooding and are subject to further study through a scaled-down modeling approach. The screening tool is first applied at the greater watershed level to provide an initial risk assessment focused on the hydrologic response to a rainfall event given the unique characteristics and features of the sub-watershed or study area. The process is discussed later in Section 2.2 with results presented in Section 2.4.

2.1.3 Potential Preservation Areas

Walton County boasts several areas with high biodiversity value. These areas include the unique coastal dune lakes, which support diverse ecosystems and contribute to water quality along the coast. Wetlands are crucial habitats that provide refuge for a variety of plant and animal species while acting as natural water filters. State parks like Topsail Hill Preserve and Grayton Beach State Park are valuable conservation areas with diverse coastal ecosystems. Additionally, preserving the Choctawhatchee River Basin is essential for the biodiversity of the region.

2.2 Vulnerability Maps

2.2.1 Screening Tool

The screening tool utilizes topographic data from various sources (Section 1.1), water table elevations (Section 1.2) and surface water gauges (Section 1.3) downloaded from the NWFWMD website, tidal information for coastal areas obtained from the NOAA Current & Tides website (Section 1.3), soil maps obtained from the USDA (Section 1.4), and another key dataset as described previously in Chapter 1. The design storms are discussed in Section 1.6. The reason this is critical is that to do any modeling (as required by the CRS program), a screening tool should be used to identify regions with a high risk of inundation based on multiple collected datasets and hydrological models. Figure 29 shows how the GIS layers interface in the tool and how they are combined for spatial analysis.

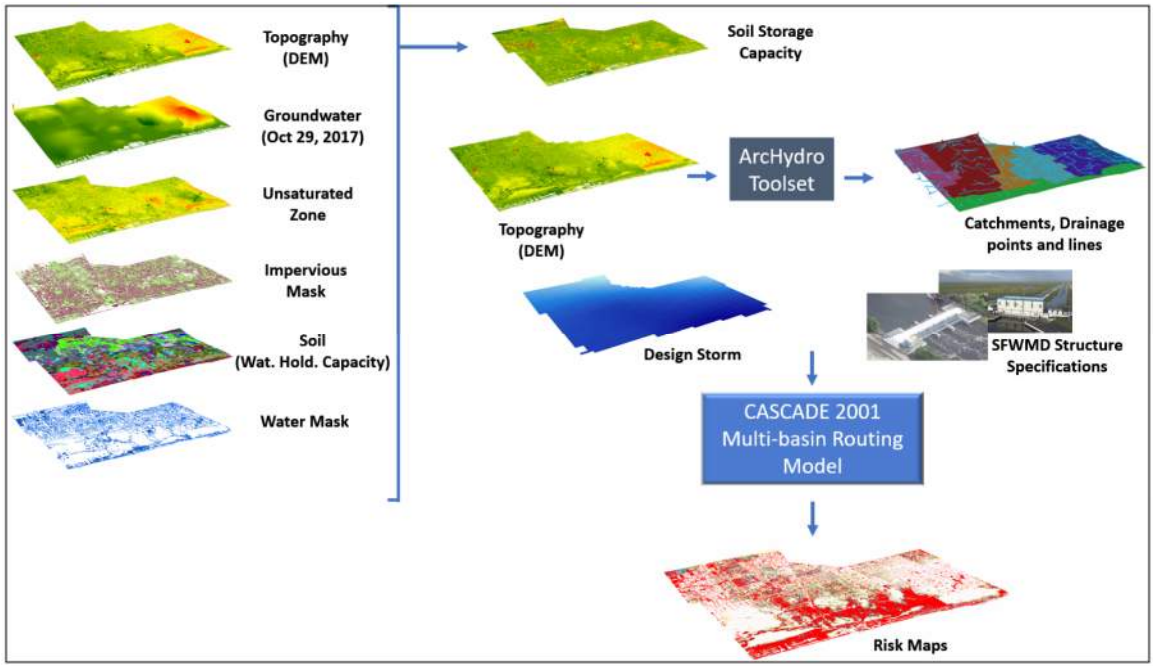

Figure 29. Screening tool methodology for creating flood risk maps.

The model chosen for this screening tool is Cascade 2001, which is a multi-basin hydrologic/hydraulic routing model developed by the SFWMD. The model permits the investigator to run different storm events to determine flooding scenarios. The boundaries are critical for basin studies and must be chosen carefully. The following data layers collected in the prior section are processed to develop the input files for Cascade 2001:

- Topography
- Soils
- Development intensity
- Groundwater elevations
- Surface water/Outlet locations

The software creates a glass box where water rises to a certain level and then decreases. Running the simulation requires defining the basin (HUC or sub-HUC) and input of the following data:

- Area
- Portion of area above a given elevation
- Initial groundwater stage
- Longest travel time for the runoff to reach the most distance point of discharge
- Ground storage as estimated from the USDA gridded National Soil Survey Geographic Database (gNATSGO)

Ground storage ≈ (Water holding capacity) × (Surface elevation – GW elevation)

= 2 × (AWS for a soil layer of 0-150 cm) / 150cm × (Surface elevation – GW elevation)

- Available water storage (AWS) for a soil layer of 0-150 cm
- Average amount of precipitation that can be stored in the soil layer

The output from the model is an elevation surface that can be used to develop a flood map for the study area (**Error! Reference source not found.**), which shows the spatial distribution of probabilities of flooding during the modeled 1-day 100-year storm event.

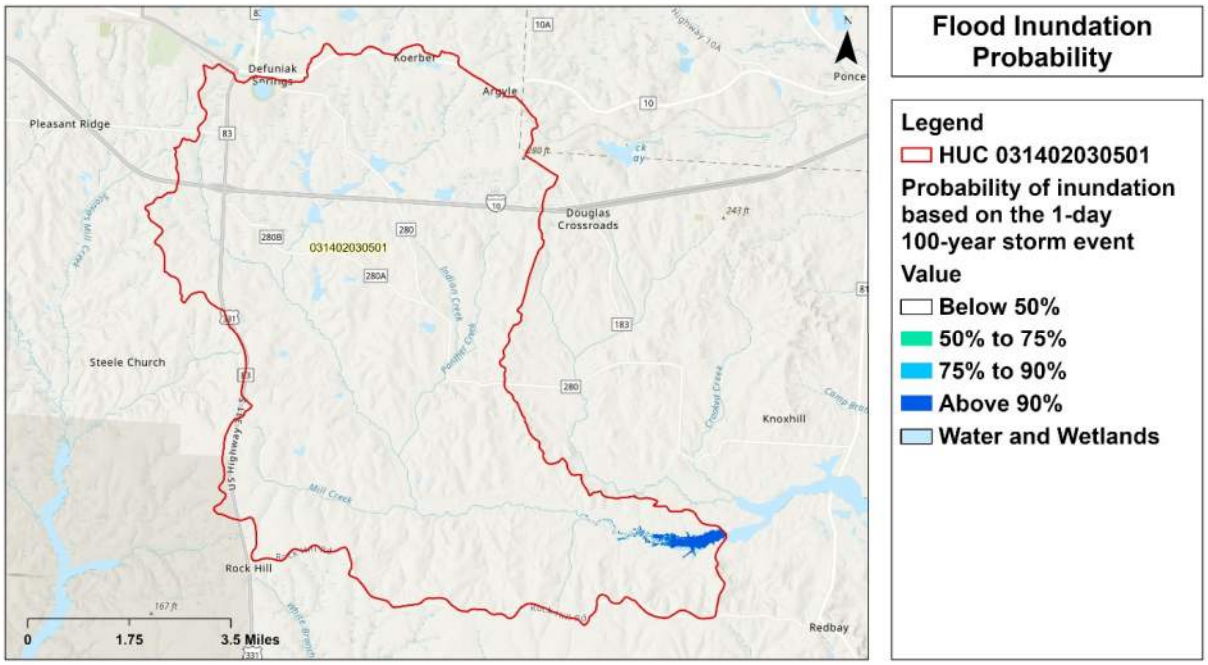

Figure 30. Probability of flood risk map during the modeled 1-day 100-year storm event for the HUC 031402030501, processed by FAU.

2.2.2 Identification of Vulnerable Areas

Given these assumptions and the Cascade 2001 outputs, the goal of this methodology is to produce a spatially-temporally quantified understanding of nuisance-destructive flood potential in the study area given observed values. Risk is a function of compounding geo-hydrological features, namely, surface water, groundwater, topography, build-out, and time of year. A GIS-based algorithm and spatial interpolation generated layers of the greatest observable hydrographic surfaces. These outputs were then compared with high resolution topographic LiDAR data to develop digital elevation models that reflect the observed risk landscape. These models can then be combined into Cascade 2001 to produce vector and volume information, in combination with soils, vegetation and impervious surfaces, allowing the observed model outputs to be extrapolated into a more predictive context.

To evaluate flood vulnerability at this scale, the analysis starts with a binary flooding surface (0 = below 50% chance of flooding; 1 = above 50% flooding) based on output from the screening tool for a specified design storm. Next, attributes of that raster based on "VALUE = 1" query are extracted using *Extract by Attributes* tool. Then the *Batch Project* tool was used to map critical facilities data to the common coordinate system (NAD83 UTM Zone 17N), unit = meters. Then a field was added using *Add Field* for [PriorityTier] = assigned Tier #1-4 value from the DOR codes and [Area_sqmeter]. The critical facilities layers were then merged into a single layer to calculate the polygon geometry for [Area_sqmeter] using the *Merge* tool. Next, *Zonal Statistics as Table* is used to calculate the SUM of flooded values ("VALUE = 1") within each critical parcel. Output table has fields for SUM (i.e., total # of flooded pixels per critical parcel) and AREA in map units of square meters (since each pixel in the flooding surface has a cell size of 3-meters by 3-meters, each area is equal to the SUM value multiplied by 9 m^2). Using the *Join Field* tool, the SUM and AREA fields are joined to the merged critical facilities layer based on a key attribute, first renaming these fields for clarity (e.g., AREA_FLOODED_3d25y). Once all field data is included, the next step involves using *Export Table* to export the dataset as a CSV file. Note that non-flooded parcels have zero flooded area, so they receive a <Null> value from the zonal statistics tool. To replace null values with zeros, we use *Calculate Field* in the attribute table along with the following Python expression (replacing the respective field name): "0 if !AREA_FLOODED_3d25y! is None else !AREA_FLOODED_3d25y!". Next, the CSV file is saved as an Excel Workbook (.xlsx). The Range is converted to an Excel Table, and the columns are rearranged in the desired order. Finally, the "percent-flooded" columns are calculated as follows:

- PCT_FLOODED_3d25y = ([@[AREA_FLOODED_3d25y]]/[@[TotalArea_sqmeter]])*100
- PCT_FLOODED_1d100y = ([@[AREA_FLOODED_1d100y]]/[@[TotalArea_sqmeter]])*100

After this calculation, the table is sorted to show the higher priority tiers and higher percent-flooded values first. To reduce the number of critical facilities shown in the final table, a filter was created to show only critical facilities with 10% or more flooded area in the parcel during both storm events. Records with duplicate parcel ID numbers were removed from the table. The results of this procedure are discussed in Section 5.2 of this document.

With respect to dams and levees, for purposes of the NFIP, FEMA only recognizes systems that meet, and continue to meet, minimum design, operation, and maintenance standards that are consistent with comprehensive floodplain management criteria. The Code of Federal Regulations, Title 44, Section 65.10 (44 CFR 65.10) describes the information needed for FEMA to determine if a levee system reduces the risk from the 1% annual chance flood. FEMA has accredited levees and Provisionally Accredited Levees (that have a specified timeframe to obtain the necessary data

to confirm the levee's certification status). If a levee system no longer meets Section 65.10, FEMA will de-accredit the levee system and issue an effective FIRM showing the levee-impacted area as a SFHA. FEMA coordinates its programs with USACE, who may inspect, maintain, and repair levee systems. USACE has authority under Public Law 84-99 to supplement local efforts to repair flood control projects that are damaged by floods. Like FEMA, USACE provides a program to allow public sponsors or operators to address levee system maintenance deficiencies. Failure to do so within the required timeframe results in the levee system being placed in an inactive status in the USACE Rehabilitation and Inspection Program. Levee systems in an inactive status are not eligible for rehabilitation assistance under Public Law 84-99. There are no levees/dams listed in the sub-watershed study area.

2.4 Modeling Results

Error! Reference source not found. to **Error! Reference source not found.** are a series of maps that depict risk of flooding in the basin based on the following scenarios:

1. 3-day 25-year storm event. Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (**Error! Reference source not found.**)
2. 1-day 100-year storm event. Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (**Error! Reference source not found.**)
3. 1-day 10-year storm event. Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (**Error! Reference source not found.**)
4. 1-day 5-year storm event. Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (**Error! Reference source not found.**)

In all storm event scenarios, a small portion of flooding is noted at the creek entrance to the HUC. As this basin is not connected to the ocean and its altitude is above 20 feet, the HUC is expected to remain unaffected by sea level rise, therefore SLR scenarios were not computed.

The design storm simulation determined that approximately 0.74% of the HUC total area or 0.41 mi^2 has a probability of inundation above 50% for a 3-day 25-year design storm. For comparison, approximately 0.51% of the HUC's total area, or 0.28 mi^2 would be expected to be inundated during a 1-day 100-year design storm. Approximately 0.47% of the HUC's total area, or 0.26 mi^2, would be expected to be inundated during a 1-day 10-year design storm. Finally, approximately 0.39% of the HUC's total area, or 0.22 mi^2, would be expected to be inundated during the 1-day 5-year storm. **Error! Reference source not found.** compares the four storm events.

Table 7. HUC 031402030501 expected inundated area by storm event.

Storm Event	Area with probability of inundation below 50% (Sq Mi)	Area with probability of inundation above 50% (Sq Mi)	Area with probability of inundation below 50% (%)	Area with probability of inundation above 50% (%)
3-day 25-year	54.94	0.41	99.26%	0.74%
1-day 100-year	55.07	0.28	99.49%	0.51%
1-day 10-year	55.09	0.26	99.53%	0.47%
1-day 5-year	55.14	0.22	99.61%	0.39%

Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations.
Processed by FAU.

2.5 Risk and Vulnerability

The screening tool modeling exercise from the prior section identified areas within the communities that are vulnerable to flooding. Higher priority concerns should be those properties or assets that are considered essential and need to be kept in service during a flooding event. All other improvements are local. To help with prioritization, the following is suggested:

- Tier 1 - Critical facility protection (water/sewer utilities, public safety, hospitals, schools, power, shelters)
- Tier 2 - Essential facilities (groceries, pharmacies, roadways)
- Tier 3 - Economic centers (protecting jobs)
- Tier 4 - At risk communities
- Tier 5 - Other urban/suburban property
- Tier 6 - Agriculture/public property/vacant/undeveloped

Error! Reference source not found. outlines the priority of land use based on DOR land use codes from the property appraiser's office and assigns an associated priority level to each parcel. Note that for residential property, identifying at-risk communities (income, age, disability, health) requires a further drilldown to the neighborhood level (i.e. wealthy neighborhoods with few older, poor health individuals would have a lower priority than at risk communities, which generally have

lower value housing and denser development). In the latter case, more people are impacted, and those people have less ability to mitigate risk. Based on these priorities, the relative risk priority DOR land use codes were evaluated based on a scale of 1 to 6, where 1 is higher priority (more vulnerable) and 6 is the least priority (least vulnerable).

Table 8. Priority of Land Use based on (DOR) land use codes. Processed by FAU.

DOR (Use code)	**Description**	**TIER (Priority of Land Use)**
0	Vacant Residential	6
1	Single Family Residential	5

101	Parcels With no Values (ROW - avenues, highways, arterials)	2
102	Parcels With no Values (Water)	6
103	Parcels With no Values (Rail)	2

Having assigned the risk priority from 1 to 6 in the DOR codes and the percentage of the parcel that floods during the applicable design storm, properties that are more critical to the function of the community can be identified. The methodology is to first convert the DOR code priority tier to its inverse scale by the following equation:

Consequence of risk factor = 7 – DOR Code Priority Tier

The flood risk factor from the screening tool is interpreted based on flooding probability. We take all parcels in tiers #1-4 that have a greater than 50% chance of flooding during a particular design storm and calculate the percent of the parcel that would flood during that event. The percentage is

converted to a 6-point scale termed as the Flood Risk Factor, shown in **Error! Reference source not found.**.

Table 9. Flood Risk Factor Classification.

Percent of Parcel Flooded	Flood Risk Factor
90-100%	6
80-89%	5
70-79%	4
60-69%	3
50-59%	2
<50%	1

The priority is further developed by assigning 75% of the importance to the consequence of flooding and 25% importance to flood risk, or three times the importance to the consequence of flooding to come up with a composite score as follows:

Flood Risk Factor × 25% + Consequence of Risk Factor × 75% = Composite Score

Example: 1 × 25% + 6 × 75% = 4.75

Those higher priority properties that received the higher composite score are where the mitigation strategies and financial resources should focus first.

2.5.1 Results

Error! Reference source not found. and **Error! Reference source not found.** depict the HUC 031402030501 sub-watershed priority of land uses showing the critical facilities that should receive priority. The first map (**Error! Reference source not found.**) exclusively displays critical facility parcels within the HUC without any flooding. The second map (**Error! Reference source not found.**) overlays critical facilities onto the 1-day 100-year storm event scenario. **Error! Reference source not found.**is a mosaic showing critical facilities overlaid in the 1-day 100-year storm event for the whole county.

Additionally, **Error! Reference source not found.**illustrates the composite score based on 1-day 100-year storm event for the HUC, which is the result of the calculations explained above, pinpointing parcels that should be prioritized. It considers only parcels classified as 1 to 4 tiers, and within the 50% probability of inundation area. Lastly, **Error! Reference source not found.** is a mosaic showing the results for composite score overlaid in the 1-day 100-year storm event for the coastal area of Walton County. As the subwatershed is not coastal, the results based on 5 ft. SLR + 1-day 100-year storm event were not computed for the basin.

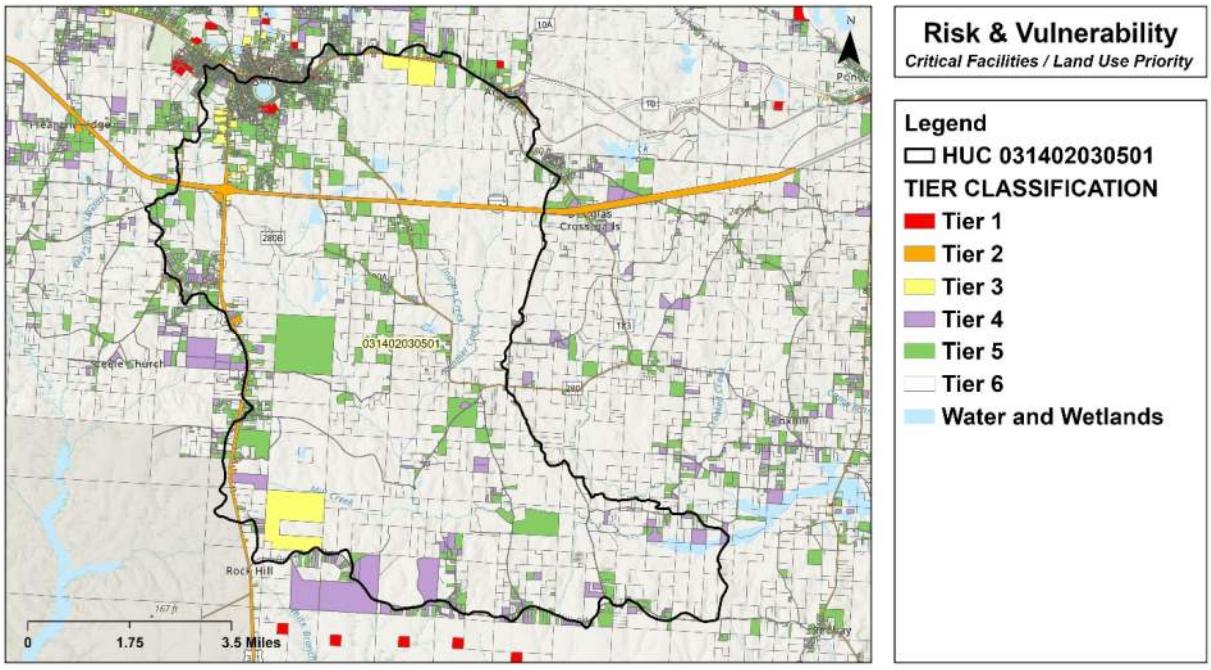

Figure 35. HUC 031402030501 sub-watershed Critical Facilities (priority of land uses) map. Processed by FAU.

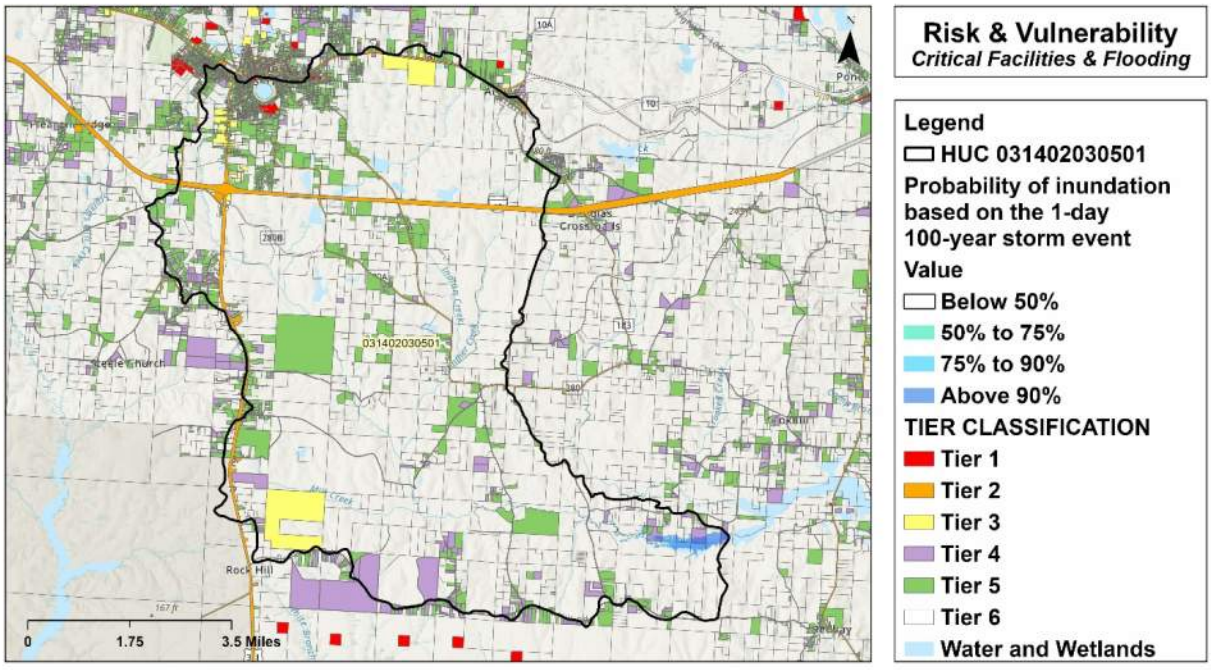

Figure 36. HUC 031402030501 sub-watershed Critical Facilities (priority of land uses) map overlaid on the 1-day 100-year storm event probability of inundation. Processed by FAU.

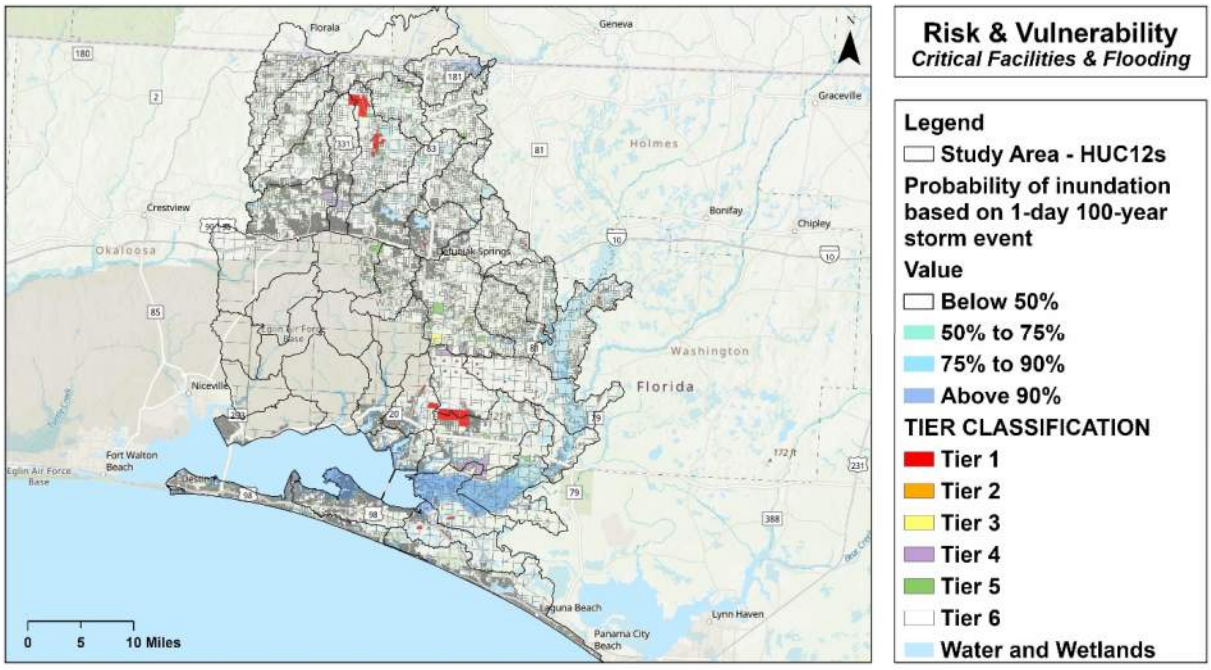

Figure 37. Walton County (mosaic) - Critical Facilities (priority of land uses) map overlaid on the 1-day 100-year storm event probability of inundation for Walton County. Processed by FAU.

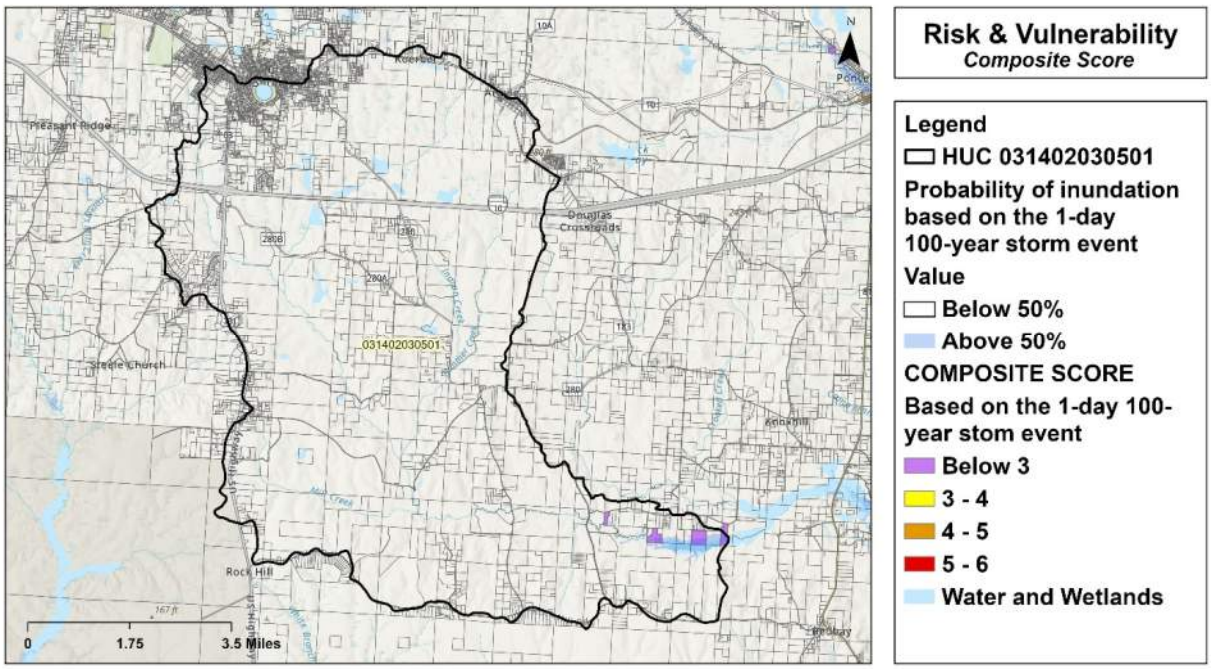

Figure 38. HUC 031402030501 sub-watershed Composite Score Risk map, with calculation based on 1-day 100-year storm event. Processed by FAU.

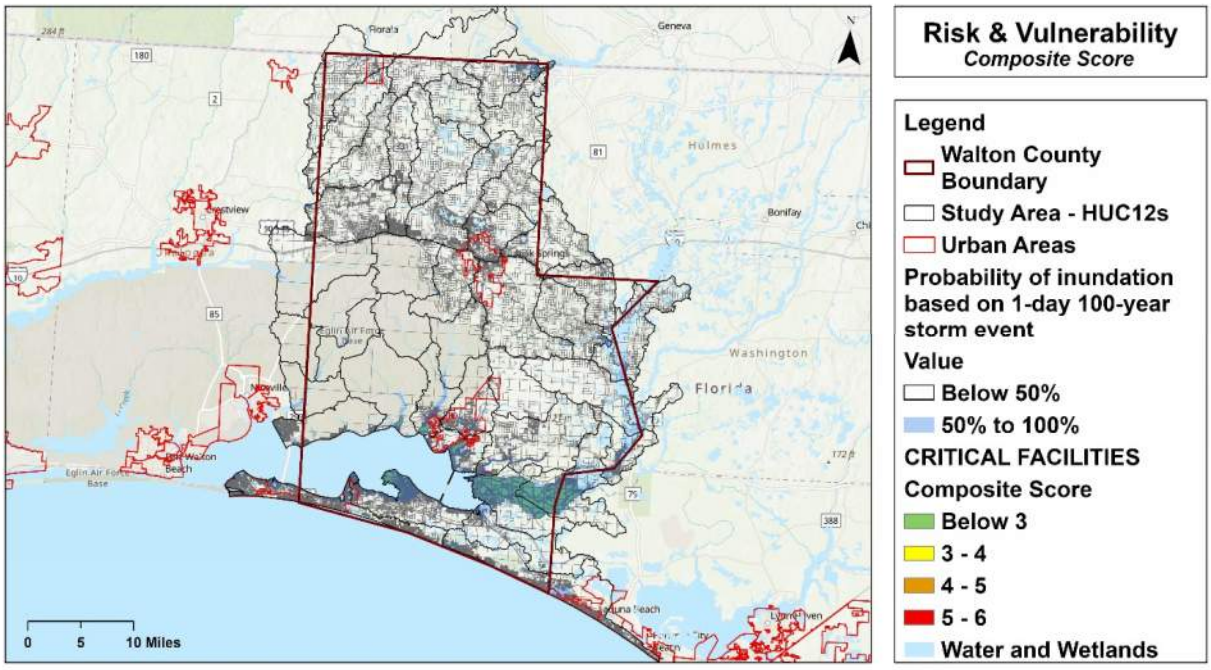

Figure 39. Walton County (mosaic) - Composite Score Risk map overlaid on the 1-day 100-year storm event probability of inundation. Processed by FAU.
Please note that due to the scale of the map, the composite score layer is not properly visible in this map.

Please note that the composite score results display outcomes exclusively for parcels within the flooding path area. Consequently, for parcels outside this flooding path, the composite results will be null. The composite score combines the flooding path area with the land use priority results to identify the most vulnerable areas deserving of priority.

2.4.2 Drill-down – DeFuniak Springs

For enhanced visualization of the urban areas within this HUC 031402030501, **Error! Reference source not found.** to **Error! Reference source not found.** illustrate the same results for critical facilities (land use priorities) and composite scores, but on a reduced scale, which better facilitates the examination of finer details within the urban area (DeFuniak Springs). These maps cover both the 1-day 100-year scenario and the 1-day 100-year + 5 feet SLR scenario, although the results for Sea Level Rise is null due to distance of the basin to the coast and its high elevation.

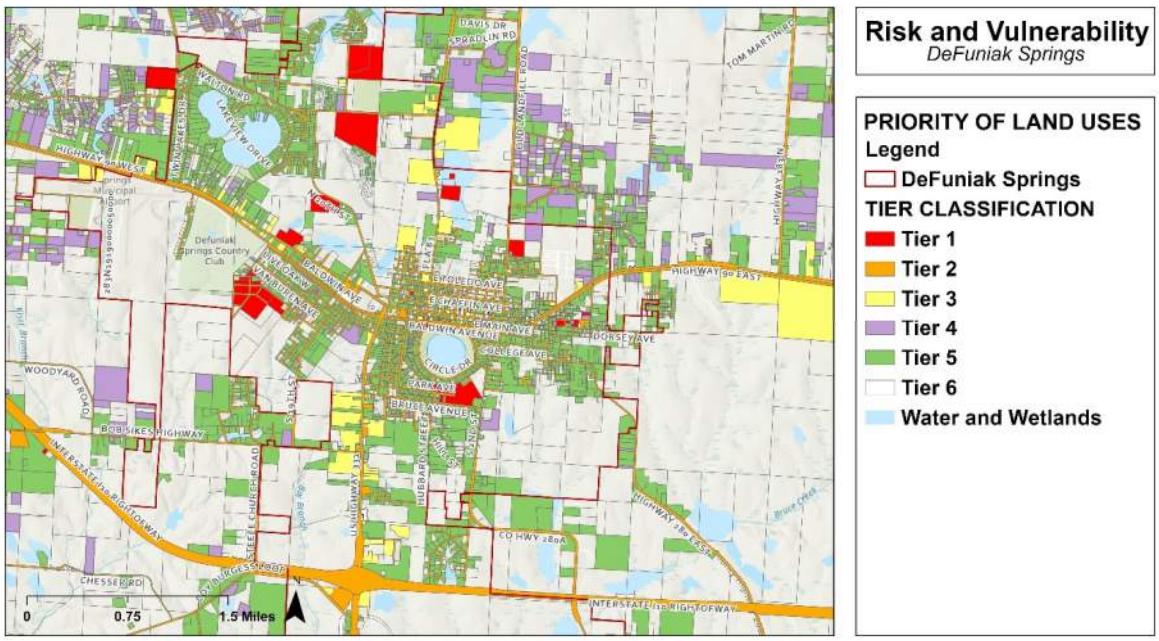

Figure 40. Critical Facilities (priority of land uses) map for DeFuniak Springs. Processed by FAU.

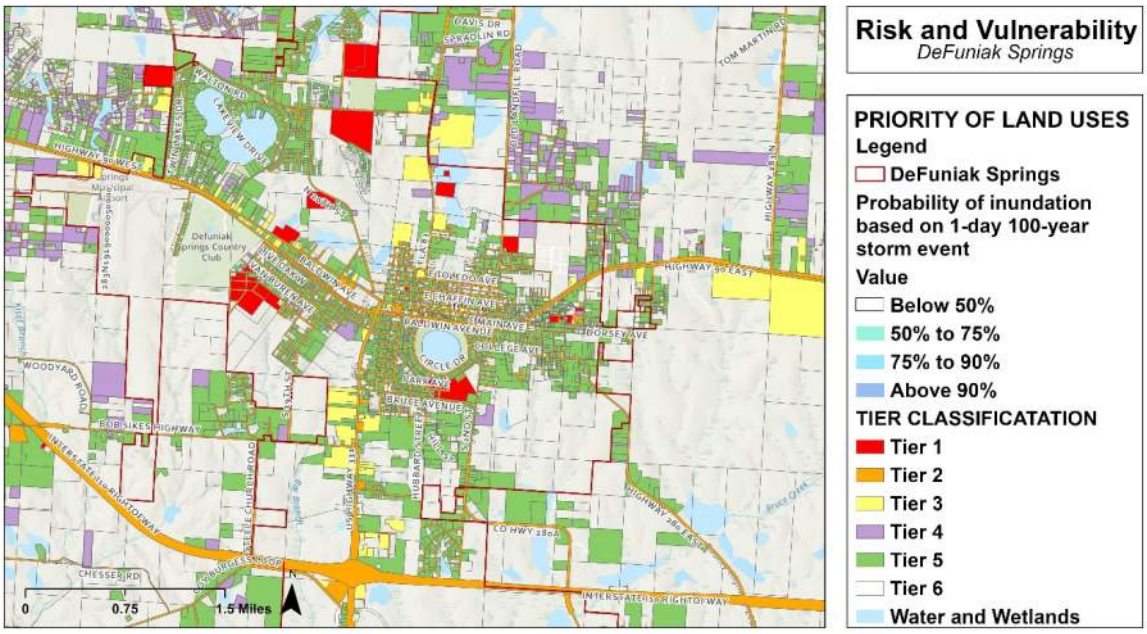

Figure 41. Critical Facilities (priority of land uses) map overlaid in the 1-day 100-year storm event for DeFuniak Springs. Processed by FAU.

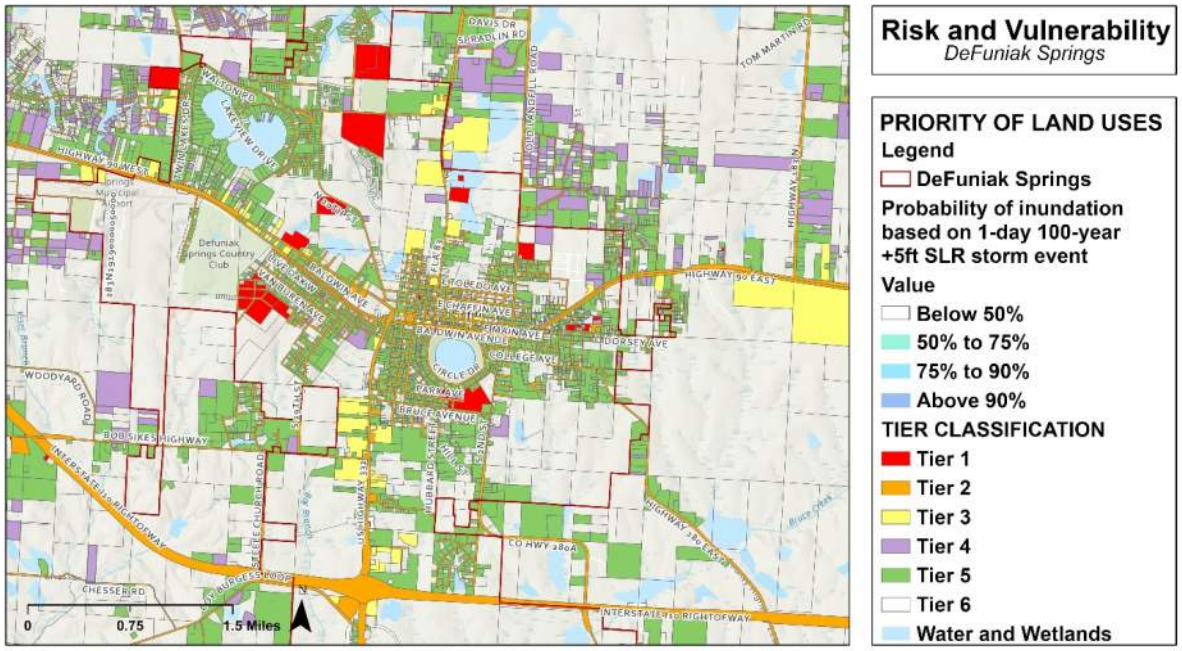

Figure 42. Critical Facilities (priority of land uses) map overlaid in the 1-day 100-year storm event + 5ft SLR for DeFuniak Springs. Processed by FAU.

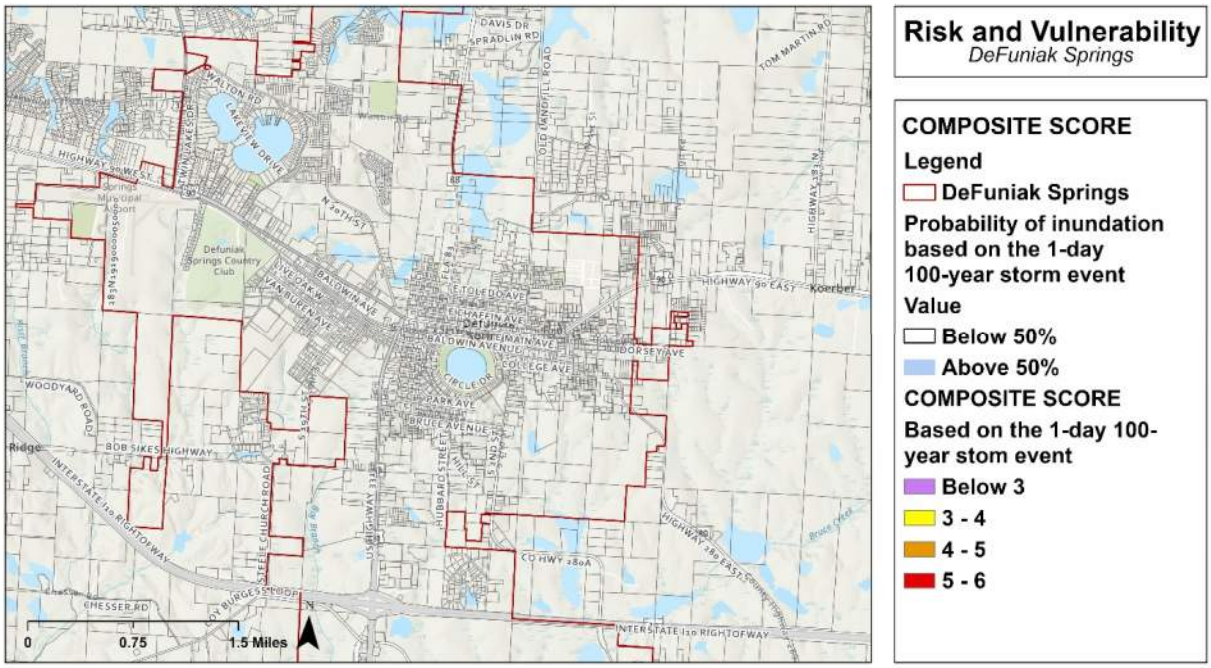

Figure 43. Composite Score map based on 1-day 100-year storm event, overlaid in flooding layer for DeFuniak Springs. Processed by FAU.

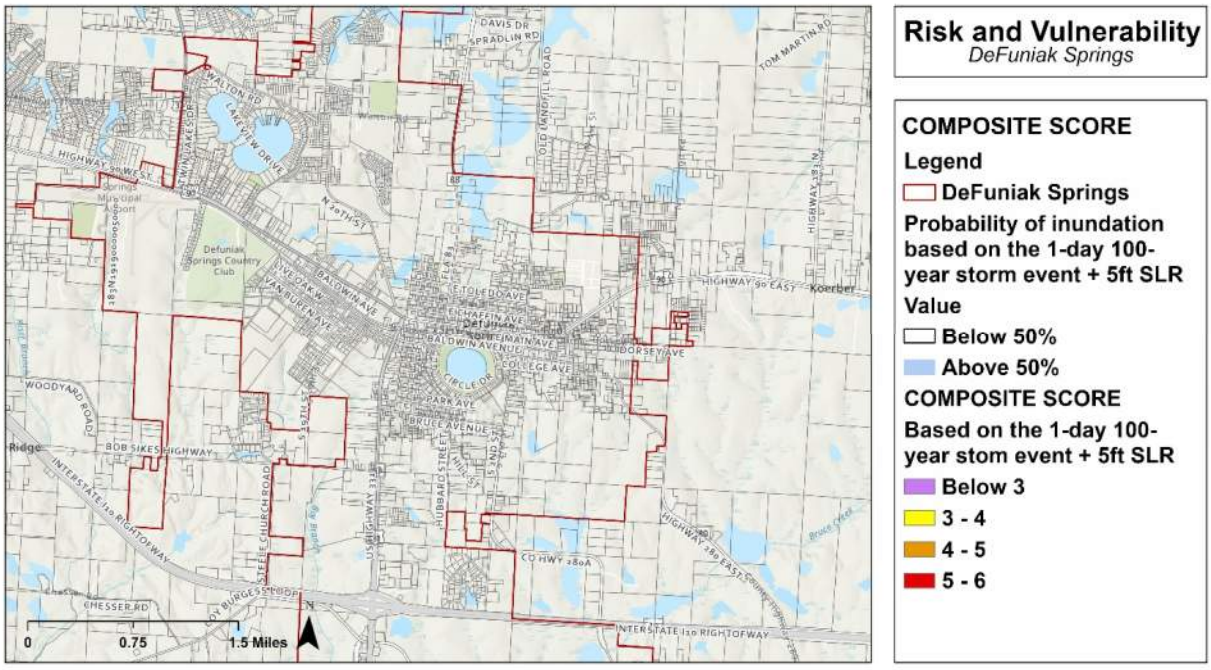

Figure 44. Composite Score map based on 1-day 100-year storm event + 5 feet SLR, overlaid in flooding layer for DeFuniak Springs. Processed by FAU.

The composite score results for this location are null, as the city of DeFuniak Springs shows no indication of flooding in both the 1-day 100-year and 1-day 100-year + 5ft SLR flooding scenarios.

2.5.3 Solutions

Chapter 5 of the Watershed Master Plan for Walton County describes a list of possible gray and green stormwater strategies to combat flooding that can be implemented as solutions for the county. The same solutions can also be applied at the HUC level, including HUC 031402030501. A summary of these flood mitigation strategies is listed in **Error! Reference source not found.**.. For more detailed information, please see Chapter 5-5.3 (Solutions).

Table 10. List of possible gray and green stormwater strategies to combat flooding.

Strategy Class	Implementation Strategy	Applications	Benefits	Cost	Barriers to Implementation
Green	Rainwater harvesting	Local, small scale, easily implemented in developed areas	Protects property, treats runoff	Under $5,000	Limited volume disposed of, so many are needed, maintenance
Gray	Pervious paving	Parking lots, patios, driveways, anything except paved roads due to traffic loading	Reduces roadway and parking lot flooding	$10-20/sf, requires bumpers and sub-base to maintain paver integrity	Must be maintained via vacuuming or the perviousness fades after 2-3 years
Green	Detention	Common for new development, but difficult to retrofit; limited to open areas	Removes water from streets, reduces flooding	$200K/ac	Land availability, maintenance of pond, discharge location Uses up land that could otherwise be developed
Gray	Exfiltration Trench	Any low-lying area where stormwater collects and the water table is more than 3 ft below the surface; densely developed areas where retention is not available, roadways	Excess water drains to aquifer, some treatment provided	$250/ft	Significant damage to roadways for installation, maintenance needed, clogging issues reduce benefits
Gray	Central sewer installation	All areas where there are septic tanks. Mostly a water quality issue	Public health benefit of reducing discharges to lawns, canals, and groundwater from septic tanks	$15,000 per household	Cost, assessments against property owners, property rights issues
Green	Flood prone property acquisition	Regional agency - could be any low-lying areas	Removes flood prone areas from risk	$2K-$100K/ac depending on whether it is already developed	Difficult to implement if occupied, issues with willing sellers, cost, lack of funds for acquisition
Gray	Pump stations	Any low-lying area where stormwater collects, and there is a place to pump the excess stormwater to such as a canal; common for developed areas	Removes water from streets, reduces flooding	Start at $1.5 to 5 million each, number unclear without more study	NPDES permits, maintenance cost, land acquisition, discharge quality
Gray	Armored sewer systems	Any area where gravity sanitary sewers are installed	Keeps stormwater out of sanitary sewer system and reduces potential for disease spread from sewage overflows	$500/manhole	Limited expense beyond capital cost

Strategy Class	Implementation Strategy	Applications	Benefits	Cost	Barriers to Implementation
Gray	Sea walls	Barrier islands and downtown coastal areas	Protects property	$1200/ft	Private property rights, neighbors
Policy	Changes in land use	Applicable universally	Achieves flood risk mitigation by adjusting permitted land use	Low but may incur private property rights conflicts and litigation	Private property rights conflicts and litigation
Gray	Roadway base protection	Low-lying areas, coastal communities	Protects roads and access routes	$1 million per lane-mile	Cost, adjacent properties become uninsurable
Policy	Enhanced elevation of buildings	Developers would implement this for new construction	Reduced flood risk	Varies	Potential issues with building structure or latticework, and existing homes that are not elevated

2.5.4 Impacted Adjustment Areas

In the evaluation of flood risk management strategies within the framework of the National Flood Insurance Program Community Rating System (CRS), the concept of impact adjustment plays a pivotal role in determining the extent to which CRS-credited activities or elements influence the vulnerability of a community's Special Flood Hazard Area (SFHA) and the structures located within it. It is important to note that while the usual results of impact adjustment are related to the SFHA area, in this specific analysis, it was used 1-day 100-year storm event inundation area performed by FAU instead.

In this context, the following table presents a breakdown of the impact adjustment calculations for a 1-day 100-year storm event inundation. The values are expressed in acres and depict the areas of interest as well as the deductions considered in the evaluation process.

The outcomes of these calculations provide valuable insights into the impact adjustment scenarios:

With ALL State Lands: This scenario reflects the remaining inundation area after accounting for deductions A, B, and C. It represents the effect of CRS-credited activities without considering the influence of state lands in managing flood risks.

With NO State Lands: In this case, the remaining inundation area is determined by considering all deductions, including state lands (both open space and not open space– see **Error! Reference source not found.**).

These calculations highlight the dynamic nature of impact adjustment within the CRS framework. By accurately gauging the influence of individual elements, the system ensures that credit allocations align closely with a community's efforts in flood risk mitigation.

Table 11. Impacted Adjustment Areas for HUC 031402030501. Processed by FAU.

AREAS	**ACRES**
HUC-12 Sub-watershed: 031402030501	35426.35
All of the 1-day 100-year storm event inundation	**180.41**
Subtract	
A. Bodies of Water in 1-day 100-year inundation > 10 acres	89.61
B. Federal Land in 1-day 100-year inundation > 10 acres	0.00
C. Reservation/Tribal Land in 1-day 100-year inundation > 10 acres	0
D. State Land in 1-day 100-year inundation > 10 acres that is open space	0.00
E. State Land in 1-day 100-year inundation > 10 acres that is NOT open space	0.00
The remainder is either:	
With ALL State Lands: All of the 1-day 100-year inundation minus (A+B+C) or	90.81
With NO State Lands: All of the 1-day 100-year inundation minus (A+B+C+D+E)	90.81

2.5.5 Repetitive Loss Property Map

A Repetitive Loss (RL) property is a building that has had two or more loss or damage due to a specific hazard, such as floods, hurricanes, or other natural disasters, over $1,000 each, paid by the National Flood Insurance Program (NFIP) within any ten-year period since 1978. There are more than 122,000 RL properties in the nationwide (FEMA, 2005).

These data are essential for assessing the vulnerability of certain areas to recurrent losses and for developing strategies to mitigate the risks. However, due to privacy concerns, the data cannot be openly shared with the public. For this reason, the data were converted into a hot spot analysis map. These maps, instead of identifying the specific location of the repetitive loss properties, highlight clusters of repetitive loss claims and areas where the probability of repetitive losses is higher than would be expected by random chance. In other words, it helps pinpoint locations that have a higher concentration of properties prone to repetitive losses. Figure 45 indicates the results from hot spot analysis in point data, showing aggregated counts, and raster data, showing the estimated probability of repetitive loss.

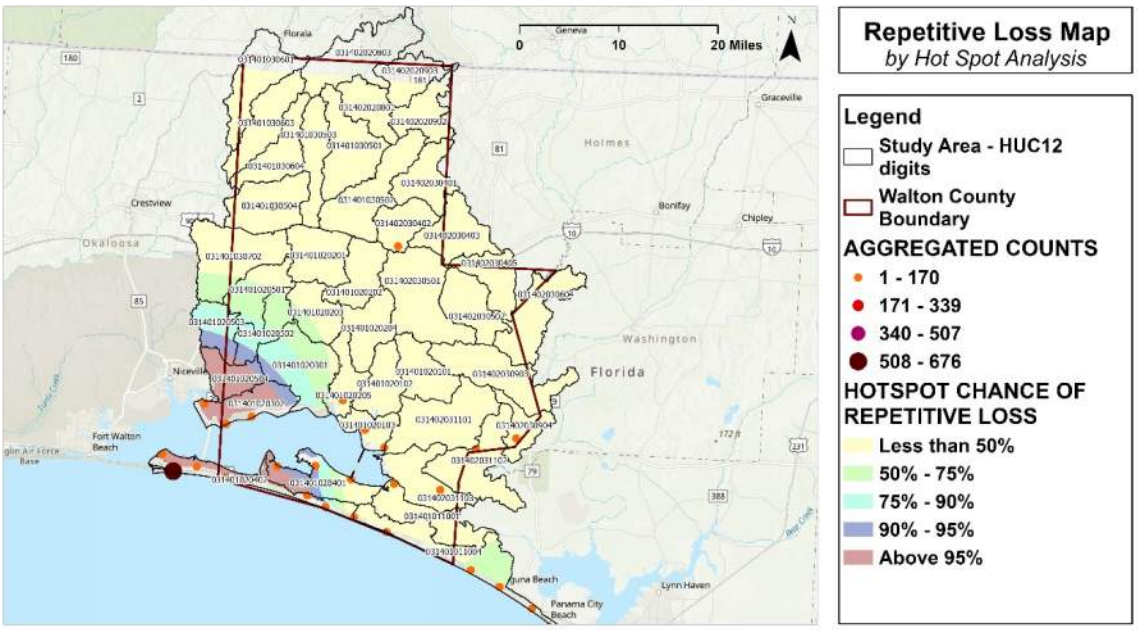

Figure 45. Repetitive Loss map for Walton County by Hot Spot Analysis. Processed by FAU.

2.5.6 Priority Projects

Although the basin features a significant amount of developed land, including a portion of the city of DeFuniak Springs, only a few of them are within the flooding zone, once flooding in the area is relatively minor and not alarming. Consequently, when considering the composite score, it is notable that most of the results are null. There are only five exceptions within the basin: one road (Walton Bridge Rd) within score 3-4, and four mobile homes, with score below 3.

X.0 EXECUTIVE SUMMARY

The goal of the appendices to the watershed plan are to outline the issues associated with the individual HUC12s that contribute or impact the community's flood vulnerability and there for its flood protection efforts. Floodplain analysis includes developing a watershed model and identifying associated inundation polygons. It builds upon information generated from the watershed evaluation so that planning and management decisions can be formulated.

This appendix describes the issues and modeling associated with one of the HUC12s that affects Walton County. In developing the County-wide plan, this HUC 12 was analyzed so as to determine how it brings or removes floodwaters from the County. For the NFIP process the goal is to analyze all communities at the HUC12 level. From a community perspective the HUC12 is less useful to residents than a community-wide plan. Hence in all cases the HUC12 results were mosaicked into the community-wide plan. Details can be found in the HUC12 appendices, some of which were brought into the community plan.

To reduce redundancy, information of the plans, ordinances, policies and regulations were rolled up to the community-wide plan and will not be repeated in the appendices. Likewise, the community wide mapping was parced for HUC12 use.

1.0 WATERSHED CHARACTERIZATION

In this section, key aspects of the watershed are characterized. This is important for later being able to identify the most vulnerable areas and to mobilize resources to implement an action plan. Understanding the characteristics of the watershed involves gathering existing information and data sets from previous planning efforts. It is important to note that this step is iterative and ongoing as new data are generated and projects are implemented and monitored.

To assess the historical and current conditions of the study area, the following existing data sets that characterize the physical and natural features of the watershed were obtained for each HUC-12 subwatershed in the study area:

- Topographic data (LiDAR)
- Relevant waterway locations
- Groundwater levels
- Soils data
- Land uses including vacant land, wetlands, impervious, etc.
- Precipitation records
- Catchment delineations for flood routing

In addition, the FEMA flood maps must be obtained, and the storm of interest must be identified for screening purposes (1-day, 2-year, 5-year, and 100-year events as well as the 3-day 25-year storm event to achieve class 4 in the CRS Manual). In developed areas, many sources of data are already available – the key is putting the key datasets in a format that can queried for screening to identify the priority areas of the watershed. Table 6 is a summary of datasets available at cwr3.fau.edu that were used to construct this plan.

This watershed master plan is a drilldown of the larger Walton County TMDL region, which involves 42 HUC 12-digit sub-watersheds (**Error! Reference source not found.**). **Error! Reference source not found.** shows Walton County Drainage Network and the location of urban areas (cities and towns). In **Error! Reference source not found.**, the HUC-12 digits (031402030502) is highlighted among all the HUCs to help identifying its location. (Figure 3).

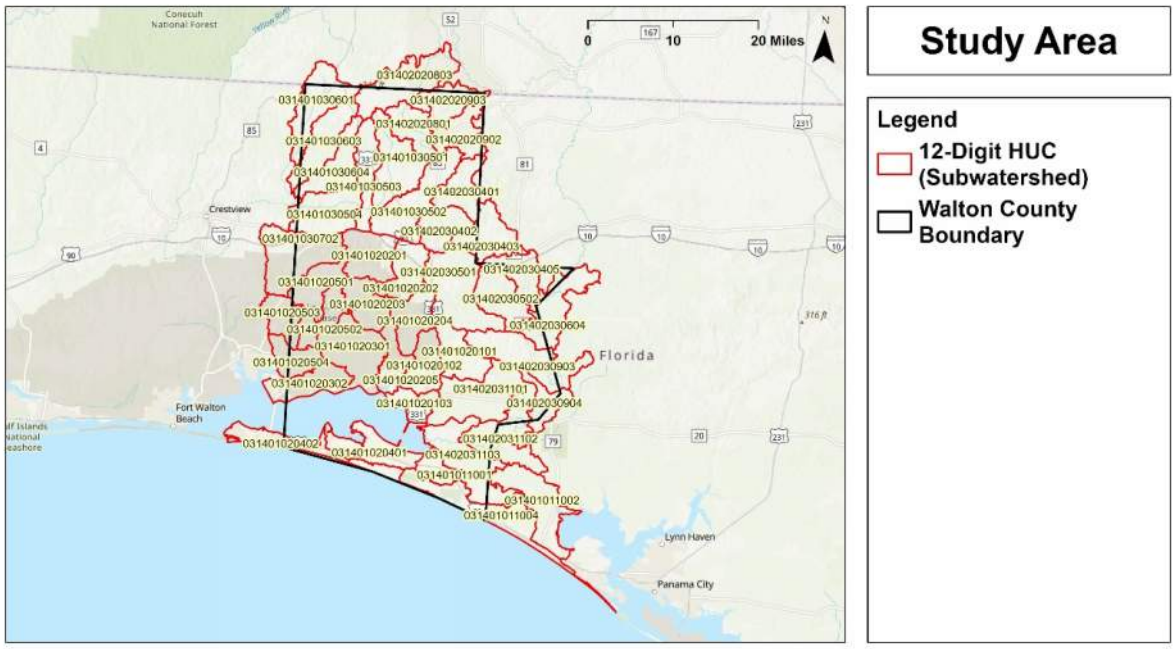

Figure 1. Walton County and all HUCs 12-digit subwatershed, processed by FAU.

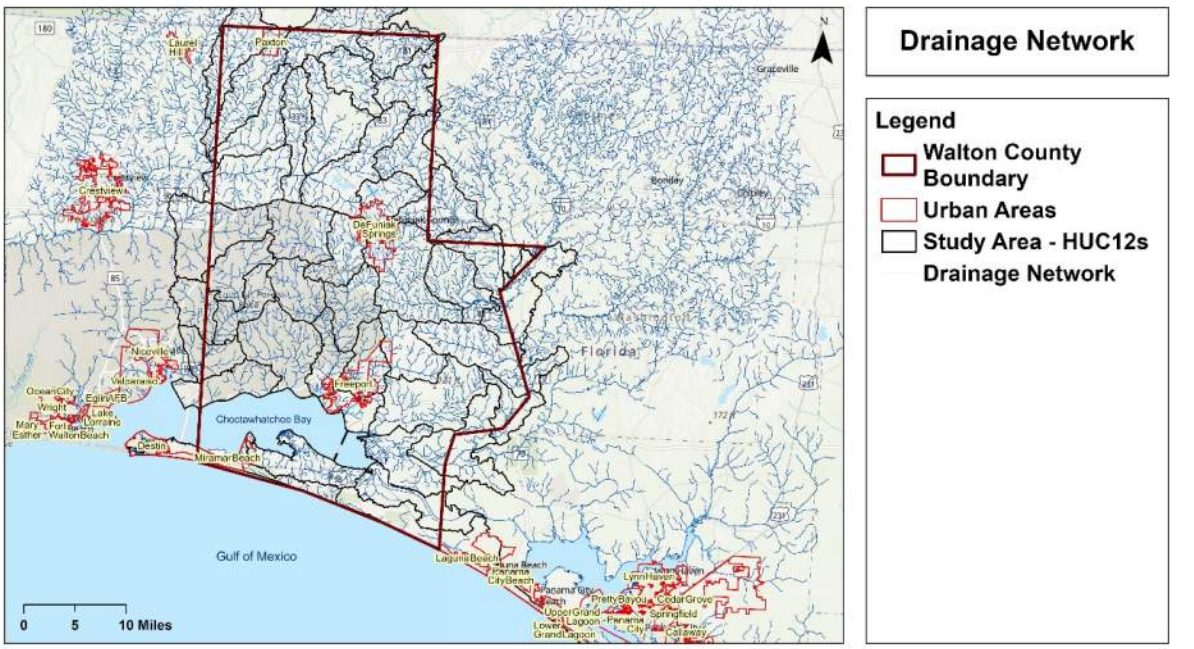

Figure 2. Walton County Drainage Network and urban areas (cities and towns), processed by FAU.

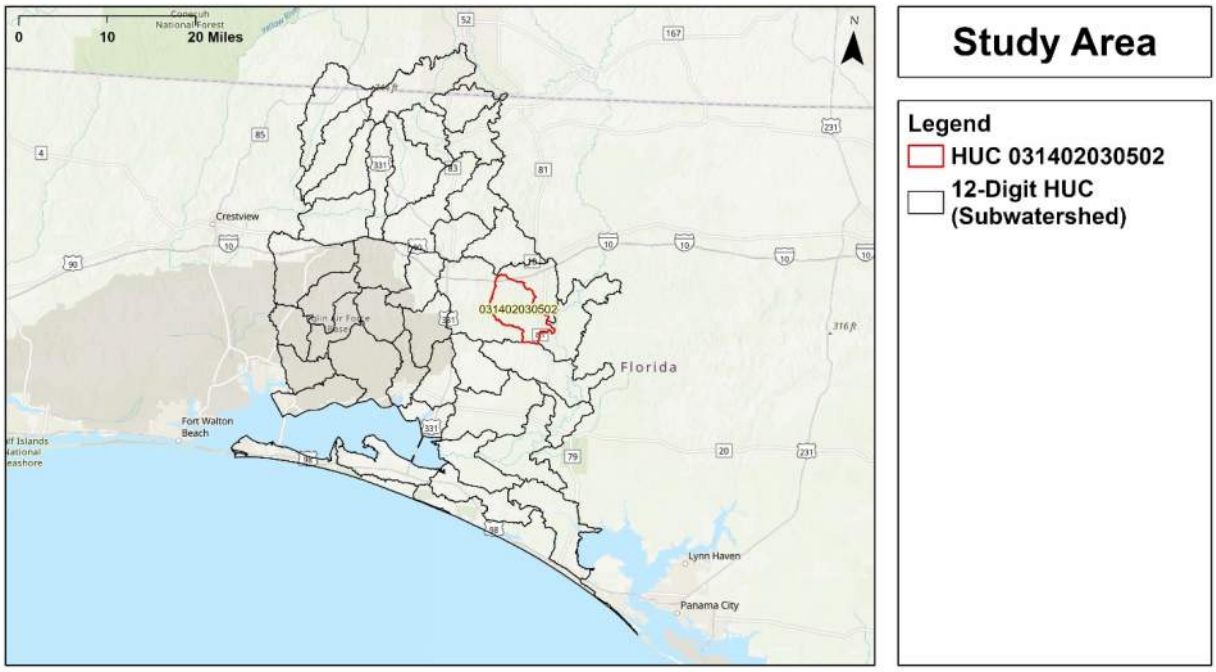

Figure 3. HUC 031402030502 sub-watershed location.

Located in the northwestern region of Florida, Walton County has 1,037.7 square miles of land and it is the 12th largest county in Florida by area, while also sits the highest point in the state, with a height of 345 feet in its northern end. With a population of 75,305 residents according to

the 2020 census and an estimate population in July of 2022 of 83,304, the county has experienced consistent growth within the past several years, driven by factors such as tourism, retirement migration, and regional population dynamics. The county was the residence for 55,043 people according to Census 2010, which leads to a percent change of 36.8% in 10 years, between 2010 and 2020, and a percentage change of 10.6% in two years, between 2020 and 2022 (United States Census Bureau).

The surge in population, particularly in the southern part of Walton County, has resulted in a corresponding expansion of infrastructure to cater to the growing needs. Essential facilities such as potable water systems, wastewater treatment plants, electrical utilities, roads, and schools have been developed to support this increasing population. However, the infrastructure expansion has brought about a significant change in the natural environment. Prior to the existing development , tropical cyclone impacts would be mitigated by natural barriers such as vegetated sand dunes, wetlands, and deserted beaches, which would absorb some of the destructive forces. Now, with the proliferation of costly infrastructure and residential dwellings in coastal areas, these storms pose a higher risk of potential damage. The very areas where development is occurring are becoming more vulnerable to the impact of severe storms, highlighting the importance of considering and implementing adequate measures to address potential storm damage in these coastal regions (Walton County Local Mitigation Strategy Plan, 2015).

Demographically, Walton County presents a heterogeneous age distribution, encompassing a blend of younger and elderly cohorts. The median age of approximately 44 years reflects the presence of both younger families and retirees seeking a serene and picturesque environment. Ethnically, the county' population is predominantly White with smaller yet notable populations of Hispanic/Latino, African American, and other racial/ ethnic groups.

Economically, the tourism sector stands as a dominant force in Walton County, constituting 23.4 percent of the workforce, according to Walton County Economic Development Alliance in 2011, due to its renowned beach destinations, such as Santa Rosa Beach, Miramar Beach, and the New Urbanist Communities of Seaside and Rosemary Beach. Following closely behind is the trade, transportation & utilities sector, accounting for 20.3 percent of employment, while construction stands at 10.0 percent in third place. Education, health care services, and public administration also play significant roles within the top five employment sectors, reflecting the diversified economic landscape of the county (Walton County Local Mitigation Strategy Plan, 2015).

The natural environment in Walton County contributes to its distinctive appeal to visitors and tourists. The county's coastal environment along the Gulf of Mexico showcases picturesque vistas, including white sand beaches, undulating dunes, and coastal dune lakes. These lakes, a rarity worldwide, provide unique ecological habitats. Walton County is also committed to environmental conservation, with designated protected areas comprising state parks, forests, and wildlife management zones. These preserved landscapes offer abundant opportunities for recreational activities, including hiking, fishing, and birdwatching.

The presence of wetlands and waterways further enhances the natural attributes of Walton County. Various rivers and creeks alongside Choctawhatchee Bay permeate the landscape, fostering

diverse ecosystems and serving as crucial habitats for a wide range of wildlife species. This rich natural heritage encourages exploration and nurtures an appreciation for the environment.

DeFuniak Springs serves as the county seat and boasts a diverse economy. Anchored by sectors such as healthcare, education, retail, government services, and a thriving small business community, DeFuniak Springs offers a range of employment opportunities. Surrounded by the natural beauty of forests, lakes, and wetlands, the city enjoys the presence of Lake DeFuniak, a noteworthy natural resource. With a population of approximately 5,100 residents, DeFuniak Springs is a vibrant city featuring a mix of economic activities. The land area of DeFuniak Springs is approximately 12.6 square miles (32.7 square kilometers).

Freeport boasts a diverse demographic profile, and a developing economy. The city is situated along the shores of Choctawhatchee Bay, which provides opportunities for recreational opportunities and supports local ecosystems. Surrounded by lush forests and intersected by waterways, Freeport enjoys a rich environmental setting. In terms of economics, Freeport's economy is in a phase of growth and diversification, with sectors including healthcare, education, retail, and small businesses. The city is also strategically positioned for future economic expansion due to its proximity to major transportation corridors. Demographically, Freeport is a close-knit community with a population of approximately 2,600 residents, comprising a mix of permanent residents, retirees, and individuals seeking a suburban or rural lifestyle. The city reflects a diverse demographic composition, showcasing a variety of cultures, and backgrounds. Freeport occupies a land area of about 13.6 square miles (35.3 square kilometers)

Further along the coast, Miramar Beach stands as a coastal gem known for its tourism and hospitality industry. Luxury resorts, vacation rentals, gourmet restaurants, high-end retail shops, and entertainment venues thrive within this bustling city. Miramar Beach's main attraction lies in its stunning white sand beaches along the Gulf of Mexico, providing endless opportunities for beach activities and water sports. Its boundaries extend into neighboring Okaloosa County, attracting a blend of permanent residents, vacation homeowners, and rental property occupants. Miramar Beach, including its neighboring areas, covers an estimated land area of around 4.7 square miles (12.2 square kilometers).

Continuing along the Gulf Coast, we encounter Santa Rosa Beach. This coastal community is renowned for its vibrant tourism industry, offering a plethora of accommodations ranging from upscale resorts to charming vacation rentals. Its demography reflects a mix of permanent residents, seasonal visitors, and individuals seeking a coastal lifestyle, resulting in a diverse and dynamic community. Santa Rosa Beach spans a larger area compared to other cities in Walton County, with an estimated land area of approximately 31.2 square miles (80.8 square kilometers).

A summary of the existing CRS classifications for the communities in the study area is listed in **Error! Reference source not found.**. No cities in Walton County are listed in the FEMA Community Rating System Eligible Communities.

Table 1: Community Rating System for Walton County. Effective April 1, 2023.

Community #	Community Name	CRS Class Rating	Premium Discount for SFHA	% Discount for Non- SFHA	Status
120317	Walton County	6	20%	10	Cycle

Based on the future land use for Walton County, only 7.07% of the land use in the county is urban and built up, and water/wetlands makes up 29.16% of the land use. The majority of land is upland forest, with 48.3%, as shown in **Error! Reference source not found.**.

Table 2. Land use table for Walton County (2023 Florida Geographic Data Library (FGDL)).

Level 1 Land Use-Land Cover Type	Area (Acres)	Percentage of Total
Agriculture	52958.94669	7.17%
Barren Land	9242.05986	1.25%
Rangeland	40326.66002	5.46%
Transportation, Communication, and Utilities	11815.69287	1.60%
Upland Forest	356796.0541	48.30%
Urban and Built-Up	52194.79061	7.07%
Water	61593.80508	8.34%
Wetlands	153759.9055	20.82%
Total	**738687.9147**	**100.00%**

Walton County has a history of flooding and has implemented various measures for flooding mitigation over the years (see section 2.12 for more details). The County has experienced flooding primarily due to heavy rainfall events and proximity to large water bodies such as the Gulf of Mexico, Choctawhatchee Bay, and numerous rivers and creeks. The topography of the region, with low-lying areas in the coastal areas and wetlands, also contributes to flood vulnerability. The proximity to the ocean (Gulf of Mexico) makes the county vulnerable to sea level rise. Over the years, Walton County has faced multiple flooding incidents, including:

- March 1997: Heavy rainfall led to significant flooding throughout the county, resulting in property damage and road closures.
- April 2009: Intense storms caused widespread flooding, damaging homes and infrastructure and resulting in the declaration of a state of emergency.
- April 2014: Heavy rainfall caused severe flooding, leading to the evacuation of some residents and the closure of roads.

Today, the goal of a stormwater management system in many communities is to keep the community as a place to live and do business while limiting risk from damage due to flooding. The short-term impacts from stormwater include flooding in low-lying areas and standing water in areas with limited soil storage capacity. Less common, but of increasing frequency, is the potential for extensive inundation of some areas, especially low-lying areas, during periods with high groundwater levels and groundwater impacted by sea level rise. As a result, there is a need to

understand the economic impact of flooding events and to create cost-effective stormwater infrastructure and policy solutions to protect property. This means preserving as much property and economic activity as possible without disrupting current activity or expending funds on inappropriate projects with limited long-term or social value.

1.1 Surface Topography

Topography is a key parameter that influences many of the processes involved in flood risk assessment, and thus, up-to-date, high-resolution, high-accuracy elevation data are required. In order to meet the requirements for FEMA Risk Mapping, Assessment, and Planning (RiskMAP), 1-meter (2015 to present) and 1/9 arc-second (~ 3-meter) (2010 -2015) LiDAR DEMs were acquired. The 1 m × 1 m LiDAR tiles were kriged to create a topographic map of the study area (**Error! Reference source not found.**). This accuracy meets the 3DEP Quality Level 2 vertical root mean square error accuracy threshold of ±10 cm for FEMA (Arundel et al., 2015). The LiDAR used for this basin was 2016.

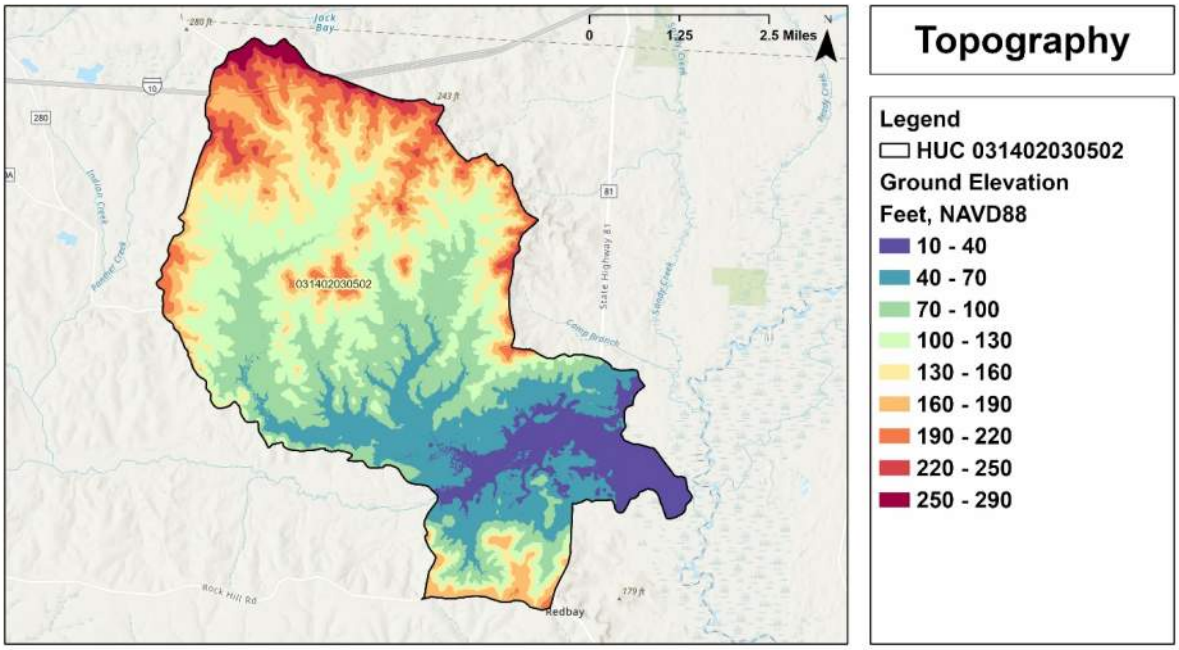

Figure 4. Topographic map of the HUC 031402030502 sub-watershed, processed by FAU.

1.1.1 Geomorphological Considerations

Walton County's coastal area is characterized by the presence of barrier islands, extensive sandy beaches, and coastal dune systems. These features are influenced by the dynamic processes of

wave action, tidal currents, and wind-driven sediment transport. The shoreline is subject to natural changes, including erosion and accretion, which significantly shape the coastal geomorphology. Inland Walton County exhibits a mix of wetlands, forests, rolling hills, and rivers. These landforms are influenced by a combination of factors, including underlying geology, fluvial processes, and the region's hydrological regime.

Like many areas in Florida, Walton County is underlain by limestone formations. The specific composition and properties of these limestone formations in Walton County may vary. However, limestone is generally known for its porous nature, which allows for the absorption and storage of water. Underground aquifers within the limestone formations can hold significant volumes of freshwater, contributing to the region's water resources.

For context, the FIRM panel index of HUC 031402030502 sub-watershed is shown in **Error! Reference source not found.**.

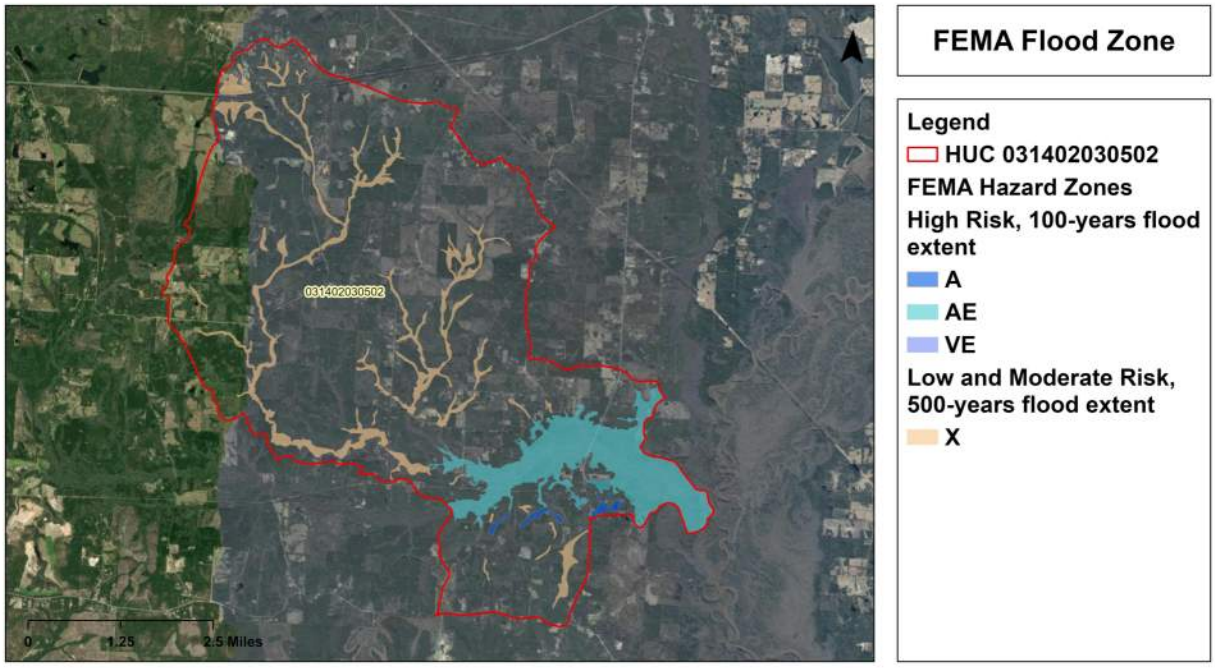

Figure 5. FEMA Flood Zone map (2020) for HUC 031402030502 sub-watershed, processed by FAU.

1.1.2 Waterway Features

In Walton County, Florida, the waterway features are primarily influenced by the presence of rivers, creeks, bayous, and the proximity to the Gulf of Mexico. To the south of Walton County lies the Gulf of Mexico. Sandy beaches, barrier islands, and the open waters of the Gulf itself characterize the coastline along the Gulf. The Gulf of Mexico influences the coastal processes, including wave action, tidal currents, and sediment transport along the shoreline. The combination

between sea level rise and King tide would have detrimental consequences for the county costal area, including the sub-watershed 031402030502 as it will reach the area thought Choctawhatchee Bay.

Walton County is home to several rivers and creeks that meander through its landscape. These waterways provide drainage for the inland areas and contribute to the overall hydrological system. Examples of significant rivers in the county include the Choctawhatchee River and the Shoal River. In addition, Walton County features bayous and estuaries that connect inland water systems to the Gulf of Mexico.

Choctawhatchee Bay serves as a vital estuarine ecosystem, where freshwater from rivers and creeks mixes with the saltwater from the Gulf of Mexico, serving as a vital estuarine ecosystem. This unique brackish water environment supports a rich diversity of flora and fauna, including various fish species, shellfish, migratory birds, and wetland vegetation, contributing to the overall biodiversity of the region. It also plays a significant role in the local economy of Walton County as it supports commercial and recreational fishing industries, providing livelihoods for local fishermen and contributing to the seafood industry, while also offering a range of recreational opportunities for residents and visitors alike, such as boating, kayaking, paddle boarding, and sailing. **Error! Reference source not found.** shows the bathymetry offshore.

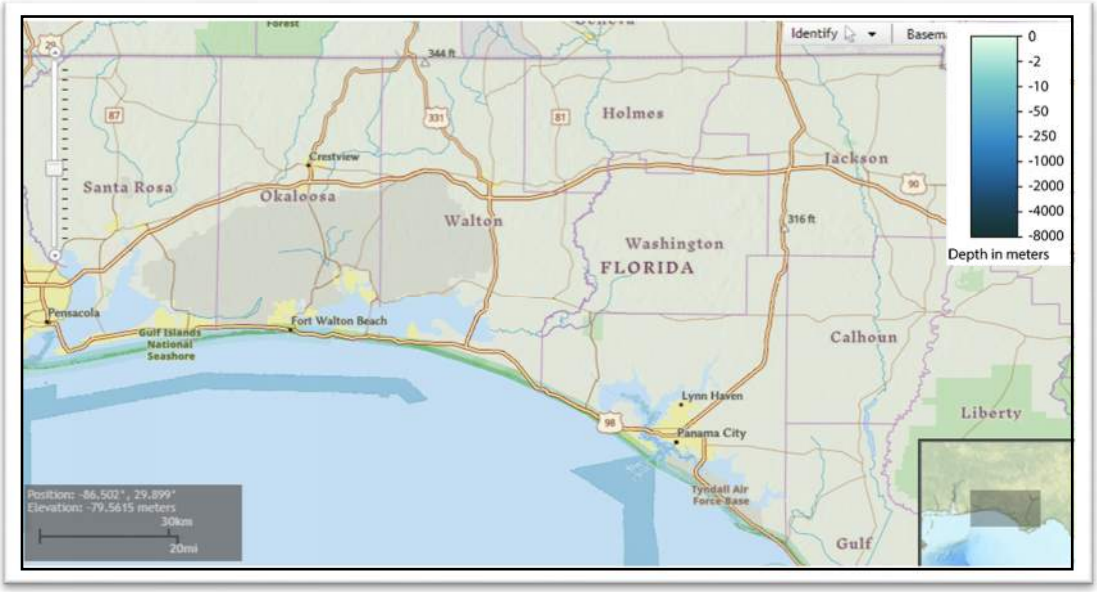

Figure 6. Bathymetry map of the shore of Walton County and surrounding counties of Florida Panhandle. Source: ncei.noaa.gov/maps/bathymetry/

Numerous tributaries exist throughout both the freshwater and estuarine portions of the watershed and can influence the overall hydrology of the area depending on rainfall and regional hydrological

conditions. **Error! Reference source not found.** shows the location of all four surface water stations along with ground water stations (wells) and the drainage network of Walton County.

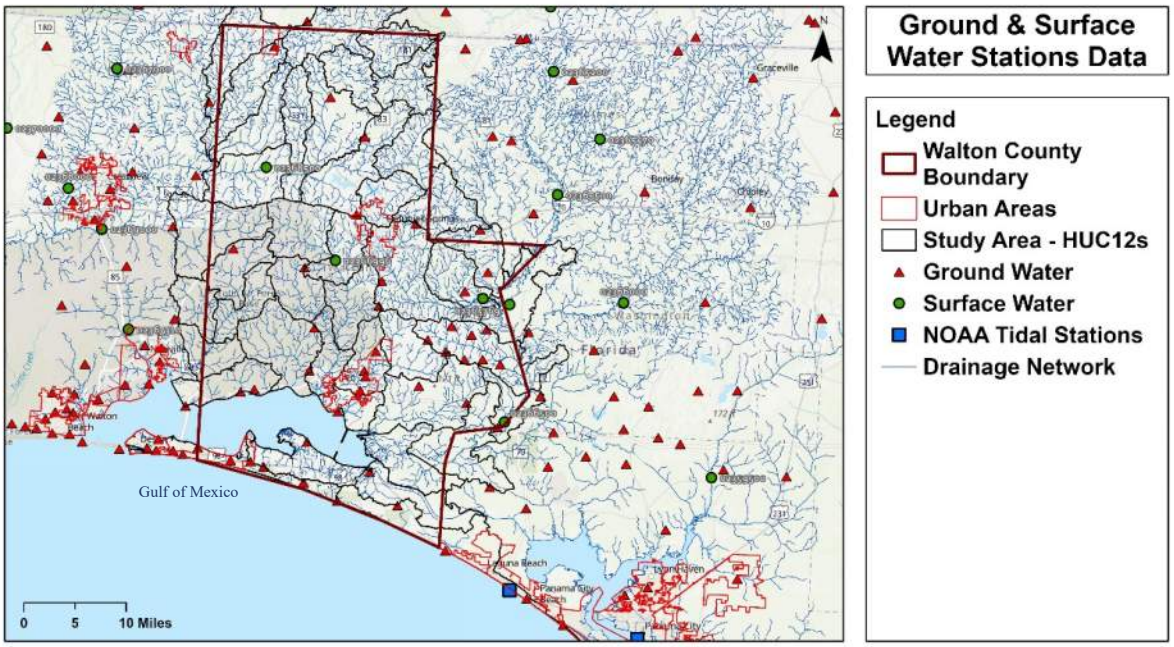

Figure 7. Ground & Surface Water Stations with drainage network for Walton County, processed by FAU.

1.1.3 Hydrologic Boundaries

The geographic area of the subject sub-watershed should be clearly defined to ensure that implementing the WMP will address all the major sources and causes of impairments and threats. Although there is no rigorous definition or delineation of this concept, one way to identify the geographic extent of the watershed master planning effort is to consult the United States Geological Survey (USGS) map of hydrologic units. A hydrologic unit is part of a watershed mapping classification system showing various areas of land that contribute surface water runoff to designated outlet points, such as lakes or stream segments. USGS designates drainage areas as sub-watersheds (including smaller drainages) numbered with 12-digit hydrologic unit codes (HUCs), nested within watersheds (10-digit HUCs). These are combined into larger drainage areas called subbasins (8 digits), basins (6 digits), and subregions (4 digits), which make up the large regional drainage basins (2 digits).

Region>>Subregion>>Basin>>Sub-basin>>Watershed>>Sub-watershed

The HUC 031402030502 has no major rivers and canals, but creeks and branches, include:

- Bruce Creek
- White Creek

- Crooked Creek
- Spears Branch
- Days Branch
- Otter Branch
- Folks Creek
- Goose Branch
- Days Branch
- Spears Branch
- Hunter Branch
- McKinnon Branch

Given that stream flow data are critical for estimating flooding, **Error! Reference source not found.** shows the historical streamflow during June 2022 to July 2023 for USGS 02365769 - Bruce Creek at SH 81 NR Redbay, FL, located inside the basin 031402030502 limits.

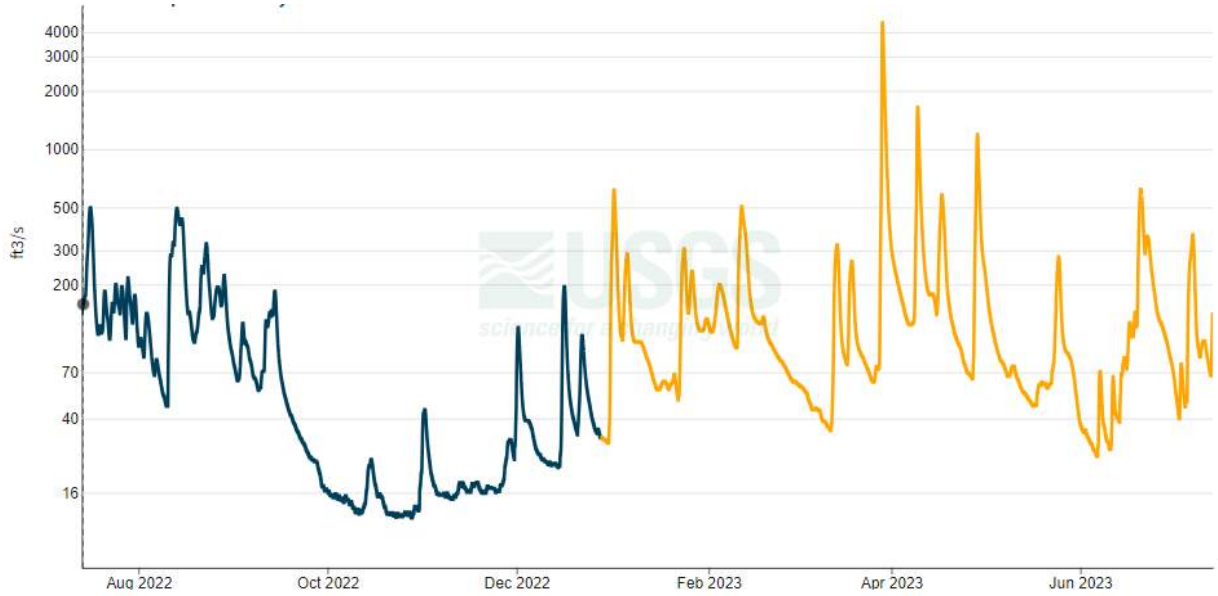

Figure 8. Average streamflow for Bruce Creek at SH 81 NR Redbay, FL (USGS 02365769 Surface-Water, June 2022 to July 2023).
Source: USGS Water Data Services (https://waterdata.usgs.gov/monitoring-location/02365769/#parameterCode=00065&period=P7D).

1.2 Groundwater

In this region of Florida, there is a direct interaction between groundwater and surface water. In addition to low land elevations and topographic relief, the groundwater and surface water are controlled by the canals, rivers, and tides. Since there is a limited number of groundwater monitoring stations, the strong relationship between groundwater and surface water was leveraged to develop a 99th- percentile surface of the water table elevation for mapping purposes. To establish a common date for modeling, the recorded groundwater table elevations were sorted in ascending order to determine the 98th - 100th percentile date of occurrence in Excel®, following the procedure

detailed in Romah (2011). This procedure was automated for this effort using a python code to process the groundwater data more efficiently. Outliers and anomalous groundwater levels in the database are initially identified (e.g. catastrophic storm events) and replaced by region-specific mean values based on observations available from the nearest well. Missing date-specific data are estimated using simple temporal interpolation based on observations available in time. If a station (or monitoring well) data contains large amounts of missing data, it is not used in the generation of the groundwater surface.

In Walton County, the average annual rainfall is abundant, reaching 65 inches at DeFuniak Springs. This rainfall predominantly infiltrates the sand-and-gravel aquifer and eventually seeps into streams or the underlying artesian Floridan aquifer. The county's two major aquifers are the sand-and-gravel aquifer and the Floridan aquifer. While the sand-and-gravel aquifer provides water for rural domestic use and plays a crucial role in water storage and streamflow maintenance, it also serves as a recharge source for the Floridan aquifer. Water from the sand-and-gravel aquifer contains varying levels of dissolved solids, pH, and iron content. The Floridan aquifer, being the primary water supply source, underlies the entire county and yields around 500 to 1,000 gallons per minute from wells, except along the Gulf Coast where the permeability is lower. Recharged by leakage from the sand-and-gravel aquifer, the Floridan aquifer's movement is predominantly southward away from the potentiometric high in northwestern Walton County. It discharges through springs, seeps along the Choctawhatchee River, and by wells. In southern Alabama, the Floridan aquifer is directly recharged by rainfall when it is exposed or close to the land surface. (Bureau of Ecology, 1974).

Once a common time period is determined across the majority of shallow groundwater wells, canal data can be gathered for that common date (and two days prior, in the event the canals were deliberately lowered). Data was obtained from the NWFWMD and processed by FAU at cwr3.fau.edu. Between stations, an ArcGIS tool permits a line to be drawn to replicate the rivers and streams to establish points for a gradient between stations. The same is true for the ocean, but it is a constant head boundary. The topography and points where streams join form boundary conditions for the screening tool on the edges of the basin and affect localized groundwater. The tide issue is resolved by using the common date for high tide.

Error! Reference source not found. shows the drainage network of HUC 031402030502 and points out the location of the ground water station in the surroundings. A groundwater-surface layer for the HUC 031402030502 sub-watershed was created using several datasets including water level data from USGS and NWFWMD and groundwater elevation contour maps. The datasets were used to generate a raster surface of the groundwater elevation (**Error! Reference source not found.**).

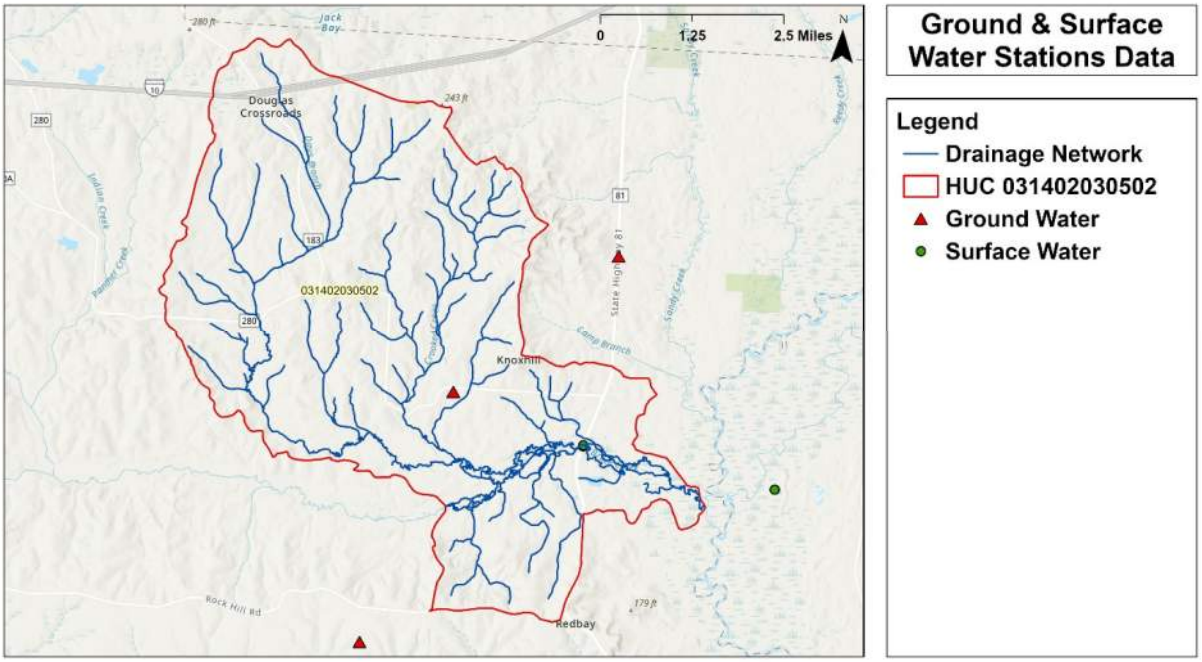

Figure 9. Ground and Surface Water Stations in the HUC 031402030502 sub-watershed, processed by FAU.

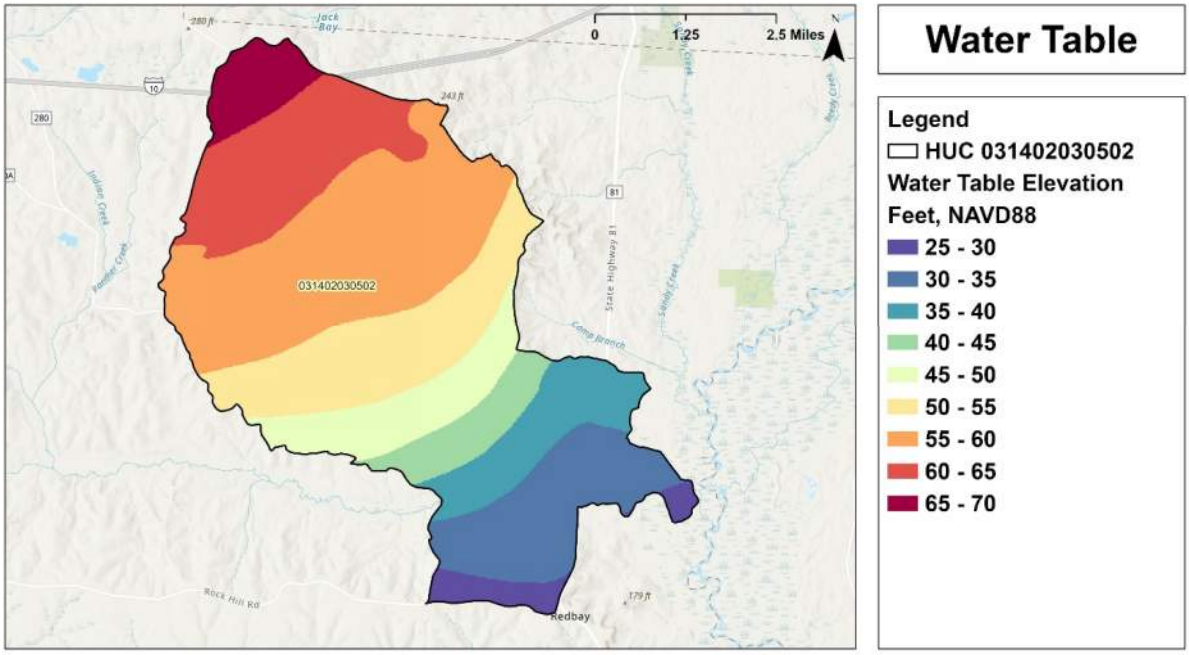

Figure 10. Elevation of the top of the surface groundwater layer for the HUC 031402030502 sub-watershed, created by multiple linear regression analysis – elevation NAVD88, processed by FAU.

1.3 Surface Water/Tides

Historically, surface water and tides have been an important factor in determining how much freshwater is delivered, how fast this water enters wetlands and estuaries, and the quality of that water. Evapotranspiration and rainfall do not coincide in the study area, which makes water supply planning difficult. **Error! Reference source not found.** shows the observed rainfall over Walton County for every month between 1900 and 2023 - each rectangle is a month and each column is a year. The 12-month total precipitation decreased 7.5 inches from May 1900 to April 2023. From May 1900 to April 2023, the average 12-month total precipitation was 60.5 inches, for the entire county.

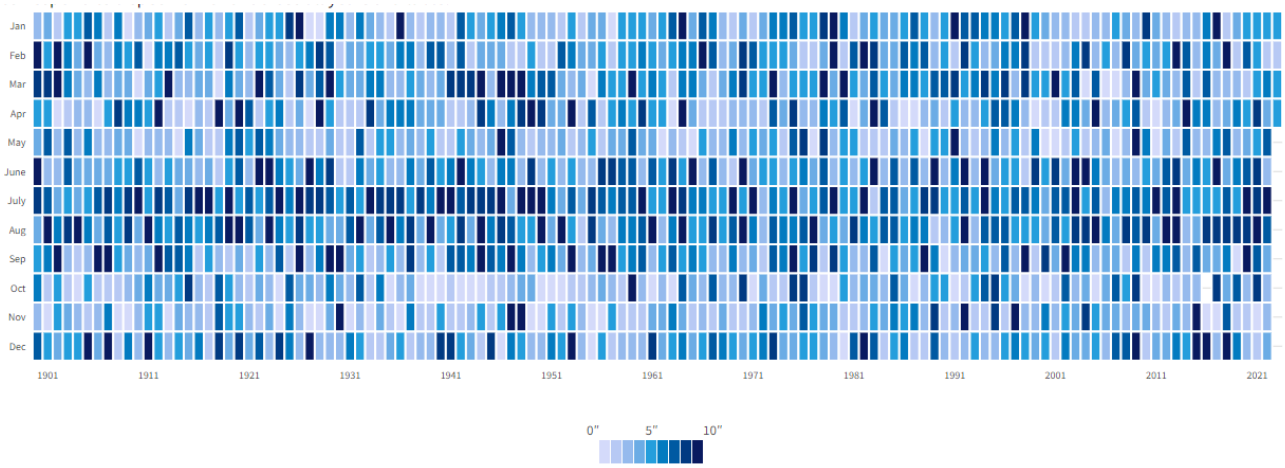

Figure 11. Monthly precipitation in Walton County, FL.
Source: National Centers for Environmental Information
(https://usafacts.org/issues/climate/state/florida/county/walton-county/#precipitation/).

While the topography (Section 1.1) and native soil (Section 1.4) create an environment that is highly permeable and capable of infiltrating significant percolation into the soil, changes in land use and land cover have resulted in water falling on impervious areas, where the water collects in pools or runs off rapidly, in direct contrast to the natural condition. This runoff flowing over impermeable regions can lead to larger scale flooding.

Tidal data can be gathered from NOAA tidal gages and other gages monitored by local governments. The location of tide gages is important to ensure they accurately depict tides, as opposed to inland waters. To set a boundary for the coastal areas, the high tide on the common date from 12/03/2018 to 12/10/2018 was selected. **Error! Reference source not found.** shows the two closest tide stations to Walton County. Since there is no NOAA tide station in Walton County, the Panama City Beach station (8729210) was used.

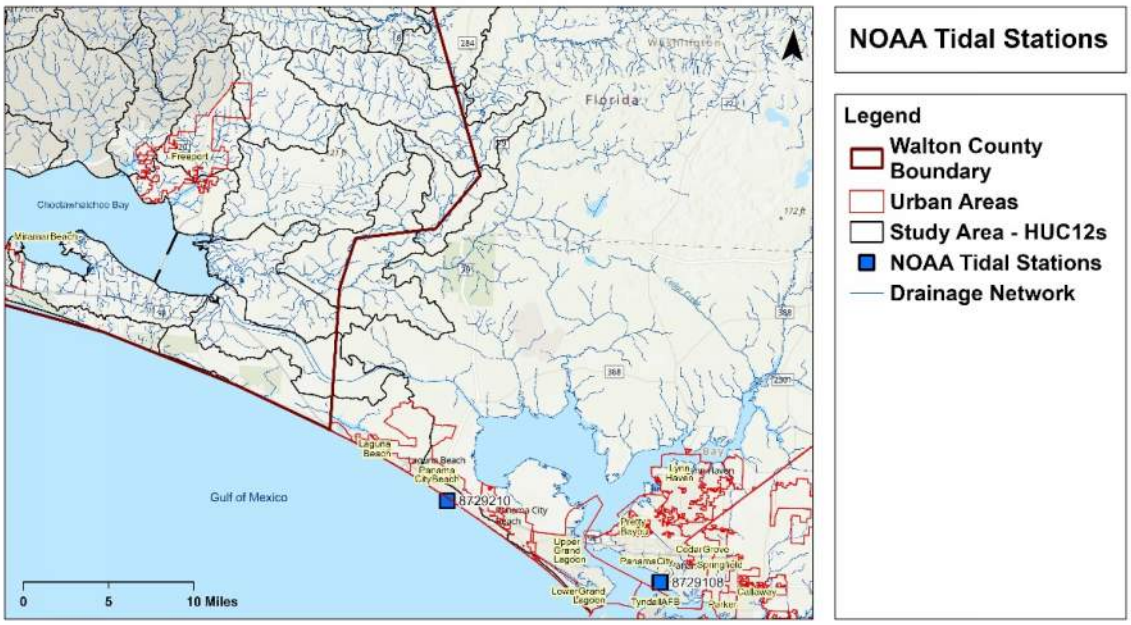

Figure 12. Locations of Florida tidal stations maintained by NOAA near to Walton County, processed by FAU.

1.4 Soils

Soil can store water if there is adequate distance between the topographic surface and the groundwater, and the soil types are capable of absorbing the water. Soil storage capacity is the volume of soil pores in the unsaturated zone that is available to store infiltrated stormwater (Gregory et al., 1998). Throughout Florida, it is common to have large volume storm events that fill the voids in the unsaturated zone as shown in **Error! Reference source not found.**.

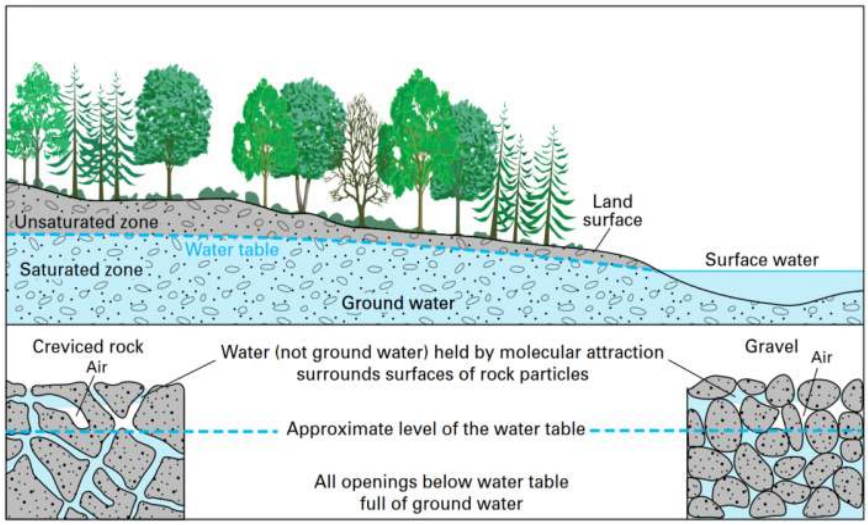

Figure 13. Zones where underground water exists.
Source: USGS, 2020.

The unsaturated zone is the portion of the subsurface above the water table that contains soil/rock and air and water in its pores as shown in **Error! Reference source not found.**. This zone affects the rate at which the aquifer is recharged by controlling water movement from the surface of the land downward towards the aquifer. During rain events, the soil voids fill up quickly resulting in the water table rising to the surface, and the surplus rainfall becomes runoff.

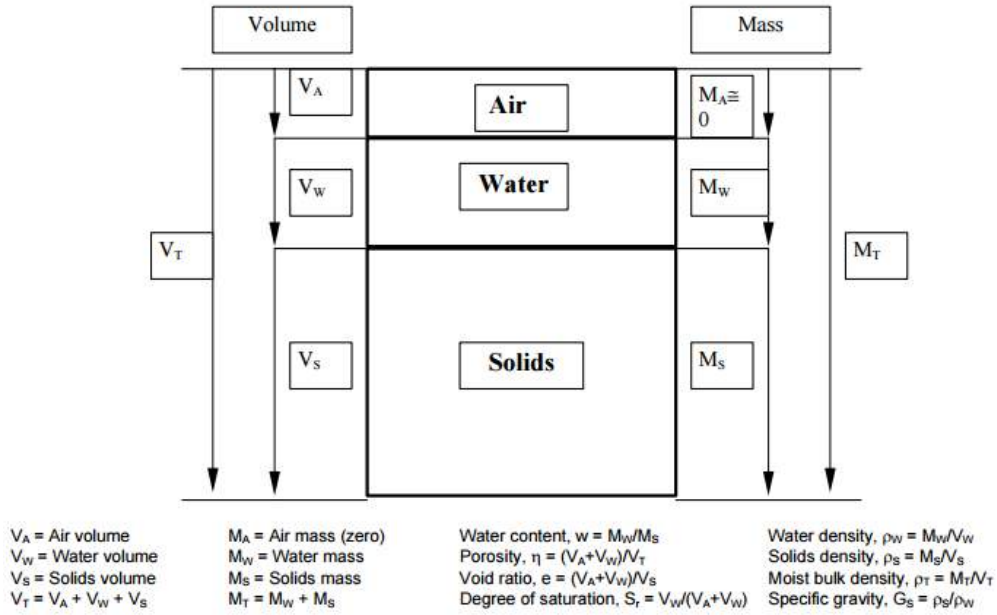

Figure 14. Saturated zone soil phase diagram and definitions.
Source: Gregory et al., 1998.

Soil data is available from the United States Department of Agriculture (USDA) or other agencies in the form of maps that can be incorporated as a GIS layer. The Gridded SSURGO (gSSURGO) dataset from USDA is chosen. This dataset is similar to the standard product from USDA Natural Resources Conservation Service (NRCS) Soil Survey Geographic (SSURGO) database, but is in the Environmental Systems Research Institute, Inc. (ESRI®) file geodatabase format. A file geodatabase allows for statewide or even Conterminous United States (CONUS) tiling of data. The gSSURGO dataset contains all of the original soil attribute tables in SSURGO. All spatial data are stored within the geodatabase instead of externally as separate shape files. Both SSURGO and gSSURGO are considered products of the National Cooperative Soil Survey (NCSS). **Error! Reference source not found.** shows the unsaturated zone found by the difference between the groundwater elevation layer and surface topography.

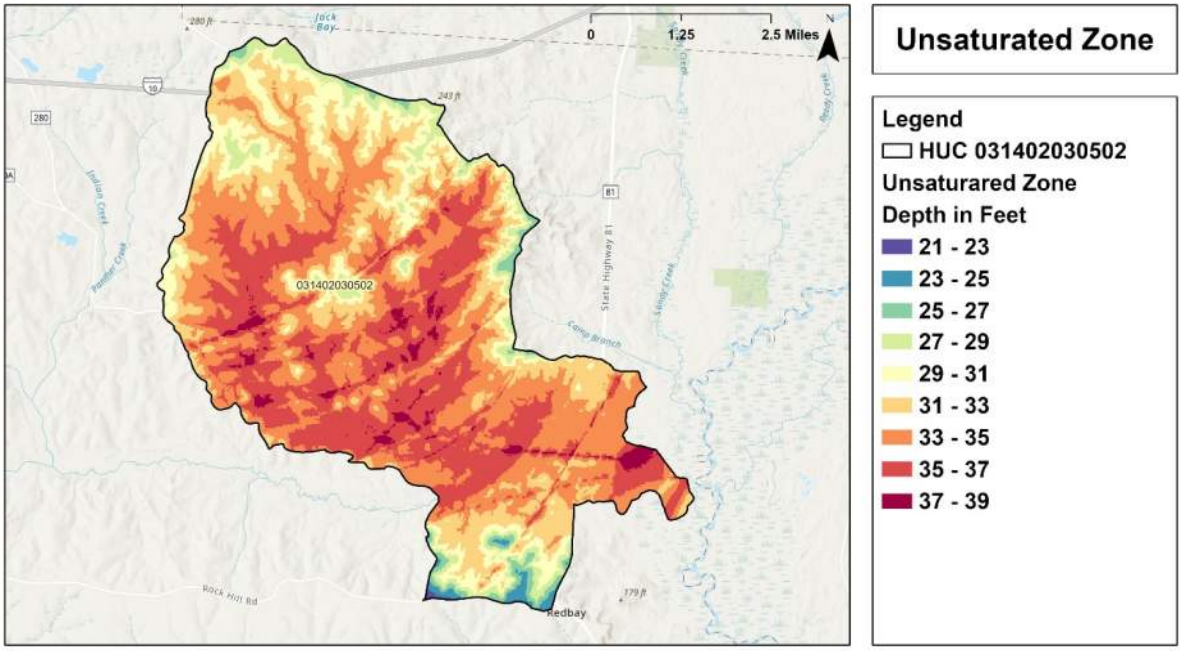

Figure 15. Unsaturated zone map for HUC 031402030502, processed by FAU.

The available water storage from USDA derived for the soil layer (0-150 cm or 0-5 ft) statewide is shown in **Error! Reference source not found.**, which covers most of Florida with a spatial resolution of 10 m. The unit is in cm. As a result of applying this layer to the study area (**Error! Reference source not found.**), the estimated soil storage capacity can be illustrated. A significant portion of the basin demonstrates a moderately favorable soil storage capacity, falling within the range of 29 to 37 feet of remaining capacity.

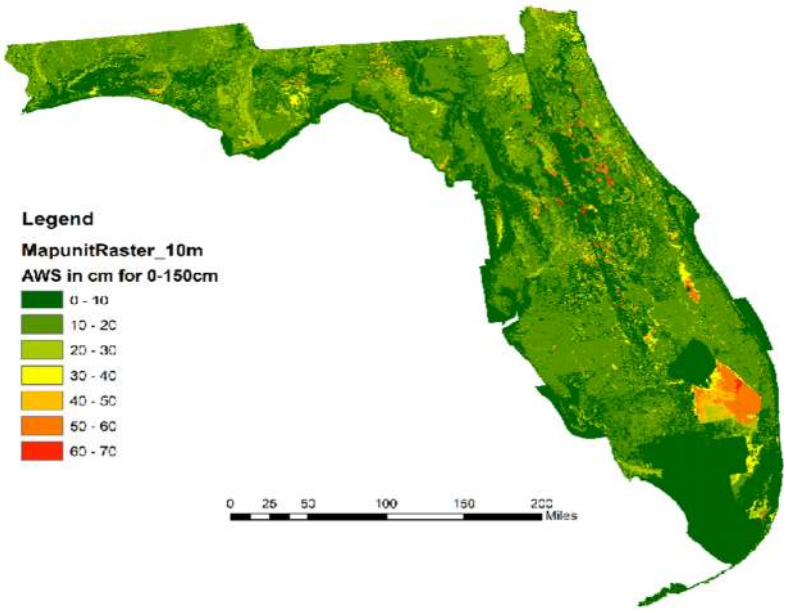

Figure 16. Available water storage derived from the gSSURGO soil database for all of Florida, as processed by FAU.

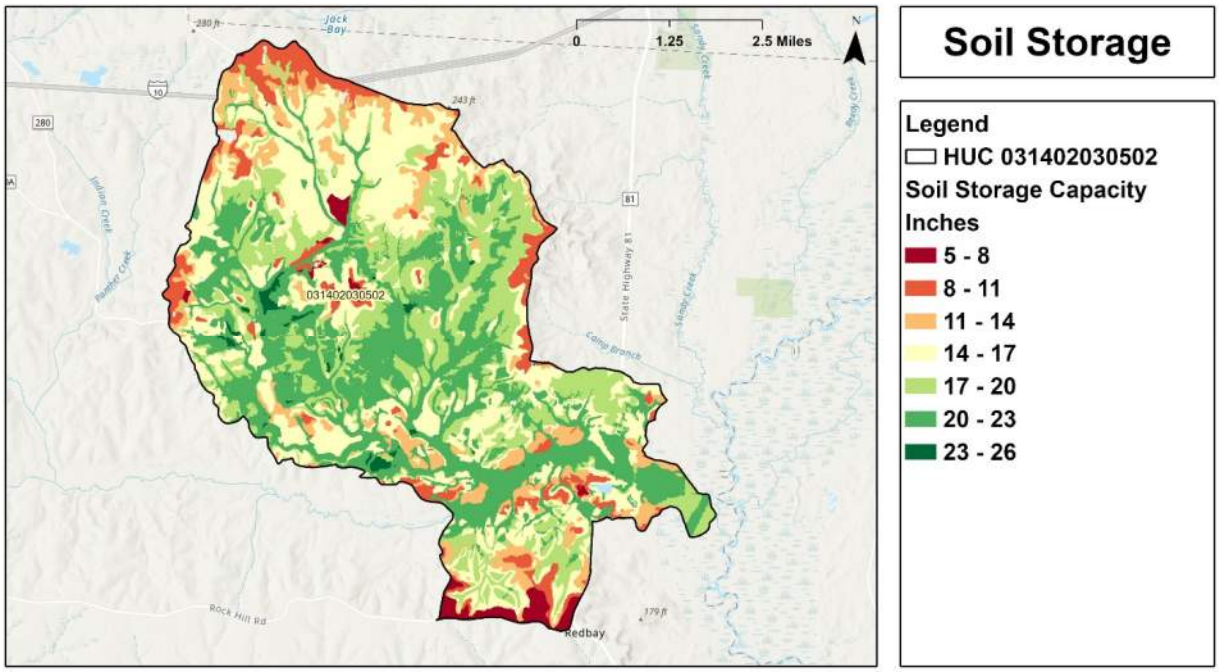

Figure 17. Water storage capacity of soil for the HUC 031402030502, processed by FAU.

Lastly, **Error! Reference source not found.** shows the water holding capacity for the basin, which refers to the capacity of a particular soil texture to retain water against the force of gravity.

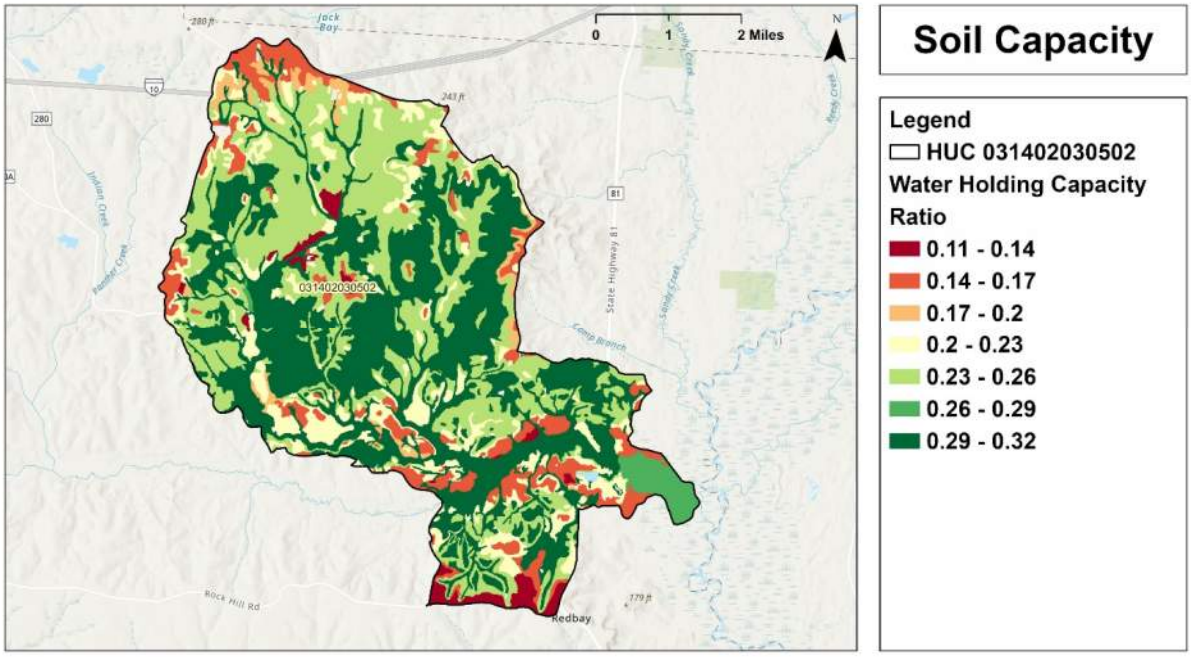

Figure 18: Water Holding Capacity (ratio) for the HUC 031402030502, processed by FAU.

1.5 Land Cover

The USGS produces the NLCD of nationwide data on land cover at a 30-m resolution with a 16-class legend based on a modified Anderson Level II classification system. NLCD is coordinated through the 10-member Multi-Resolution Land Characteristics Consortium (MRLC) to provide digital land cover information nationwide. For the conterminous United States, NLCD 2016 contains 28 different land cover products characterizing land cover and land cover change across 7 epochs from 2001-2016, urban imperviousness and urban imperviousness change across 4 epochs from 2001-2016, tree canopy and tree canopy change across 2 epochs from 2011-2016 and western U.S. shrub and grassland areas for 2016 (**Error! Reference source not found.**).

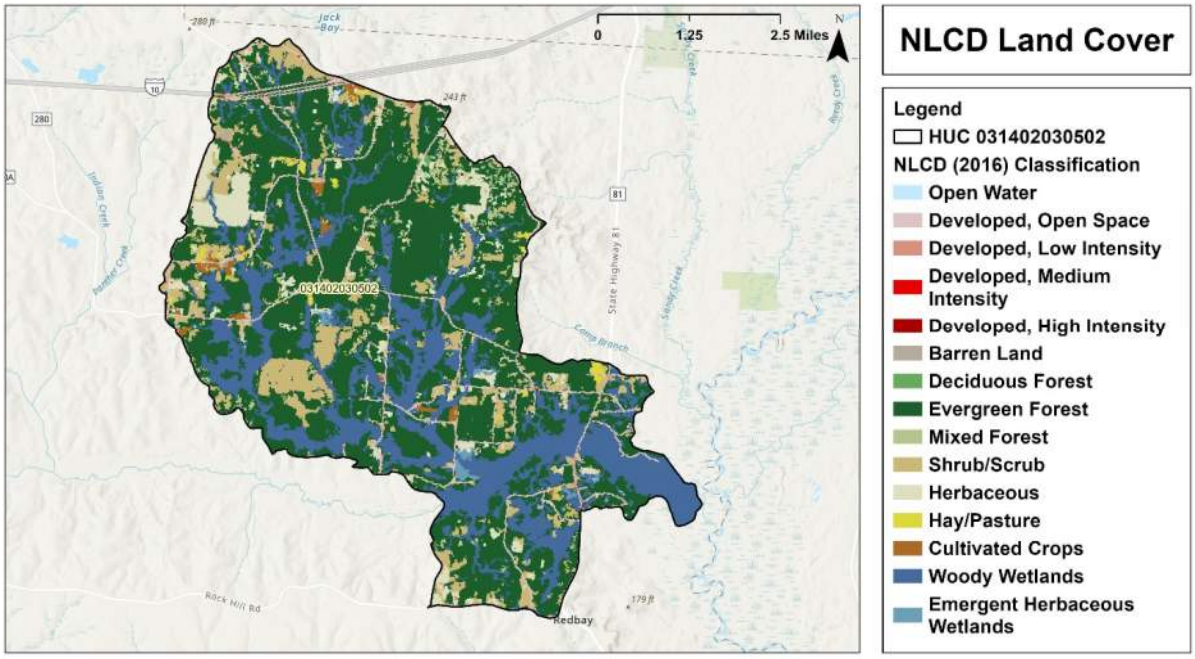

Figure 19. Land use in the HUC 031402030502 (from the NLCD 2016 database), processed by FAU.

The dataset is derived from the Florida Land Use Cover Classification System (FLUCCS), which is digitized by photo-interpretation on county-based aerial photography with varying resolution in the range of 4 in - 2 ft pixel. The NLCD2016 has a 30-meter resolution derived from Landsat imagery. Hence, the NLCD maps appear much coarser and pixelated compared to the 2023 Florida Geographic Data Library (FGDL) (https://fgdl.org/fgdlmap/) maps. A view of the latter is provided in **Error! Reference source not found.**. The future land use maps need to be used for the final land cover, as adjusted for future stormwater improvements set by regulatory standards.

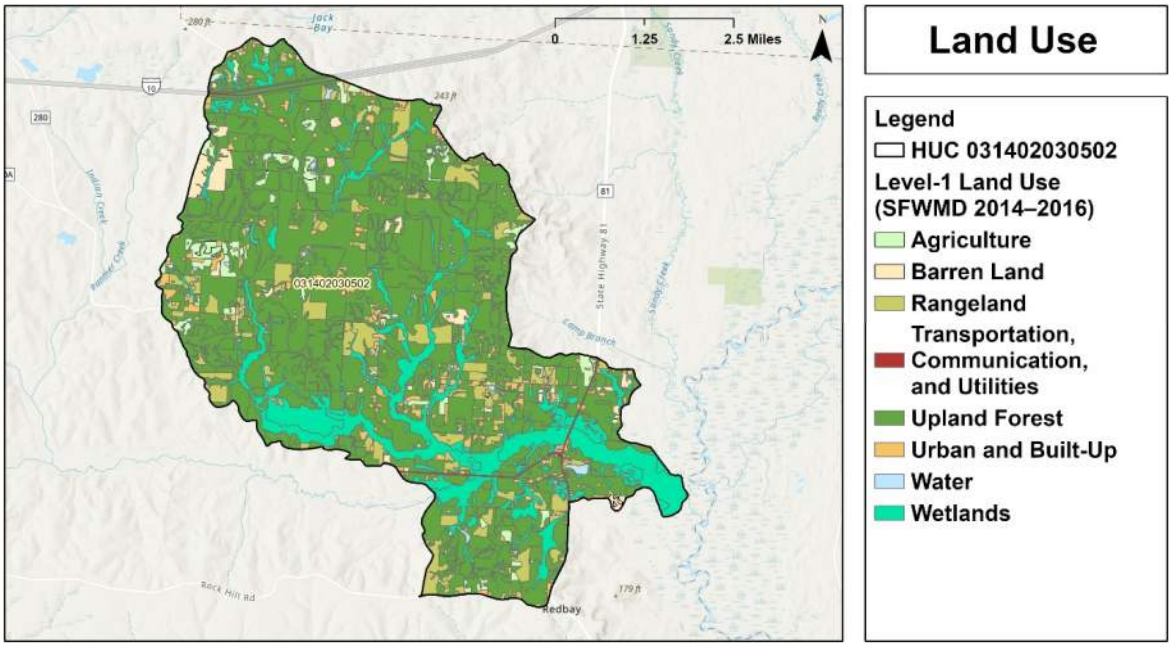

Figure 20. Land use in the HUC 031402030502 (from the 2023 Florida Geographic Data Library (FGDL)), processed by FAU.

In the HUC 031402030502 sub-watershed, the predominant land cover is upland forest, accounting for 55.58% of the area. Wetlands comes in second at 11.79%, followed by water at 9.95%, and Transportation, Communication, and Utilities at 9.25%. Developed land constitutes a minor portion, with only 3.03% categorized as urban and built-up, as indicated in Table 3 below.

Table 3. Land use for HUC 031402030502 subwatershed 2023 Florida Geographic Data Library (FGDL).

Level 1 Land Use Land Cover Type	**Area (Acres)**	**Percentage of Total**
Agriculture	1002.48	3.29%
Barren Land	463.41	1.52%
Rangeland	1704.65	5.59%
Transportation, Communication, and Utilities	2821.95	9.25%
Upland Forest	16947.87	55.58%
Urban and Built-Up	922.76	3.03%
Water	3033.80	9.95%
Wetlands	3595.27	11.79%
Grand Total:	**30492.20**	**100.00%**

Table 4. Roughness and CN Values for Each Land Use Code.

DOR Code	Use	Impervious %	Roughness
0	Vacant	0	0.4
1	Single Family	29	0.25
2	Mobile homes	21	0.05
4	Condos	60	0.05
7	Vacant –to be developed	0	0.4
8	Multifamily	60	0.05
TH 101	Townhomes	91	0.025
94	Road Right-of-Ways	50	0.08
	Open water	100	n/a
All others	Commercial, etc.	50	0.07

2.6 Precipitation

Rainfall used in the screening tool is based on the SFWMD 3-day 25-year storm, but can be modified for any rainfall event using the accumulated rainfall table obtained from NOAA Atlas 14 Point Precipitation Frequency Estimates (https://hdsc.nws.noaa.gov/hdsc/pfds/pfds_map_cont.html). **Error! Reference source not found.** shows the 3-day 25-year rainfall map based on the NOAA Atlas 14 dataset for the whole state. **Error! Reference source not found.** to **Error! Reference source not found.** rainfall 1-day 100-year, 1-day 10-year, and 1-day 5-year storm event scenarios, in inches.

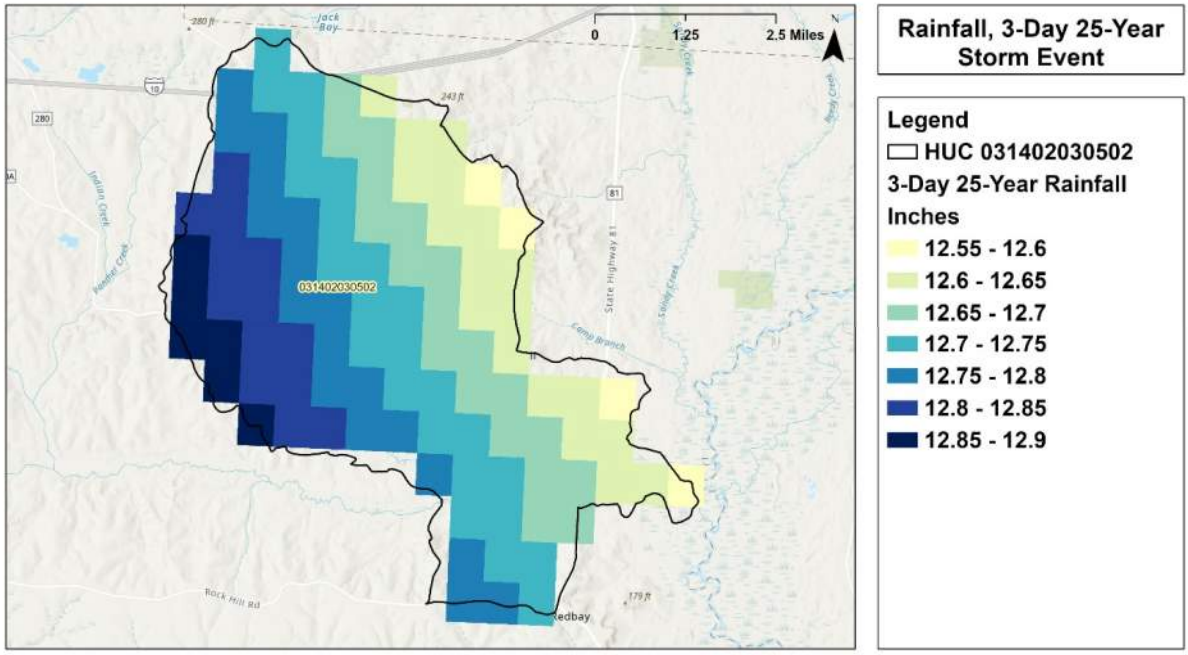

Figure 21. Rainfall distribution map across HUC 031402030502 sub-watershed, for 3-day 25-year storm event, processed by FAU.

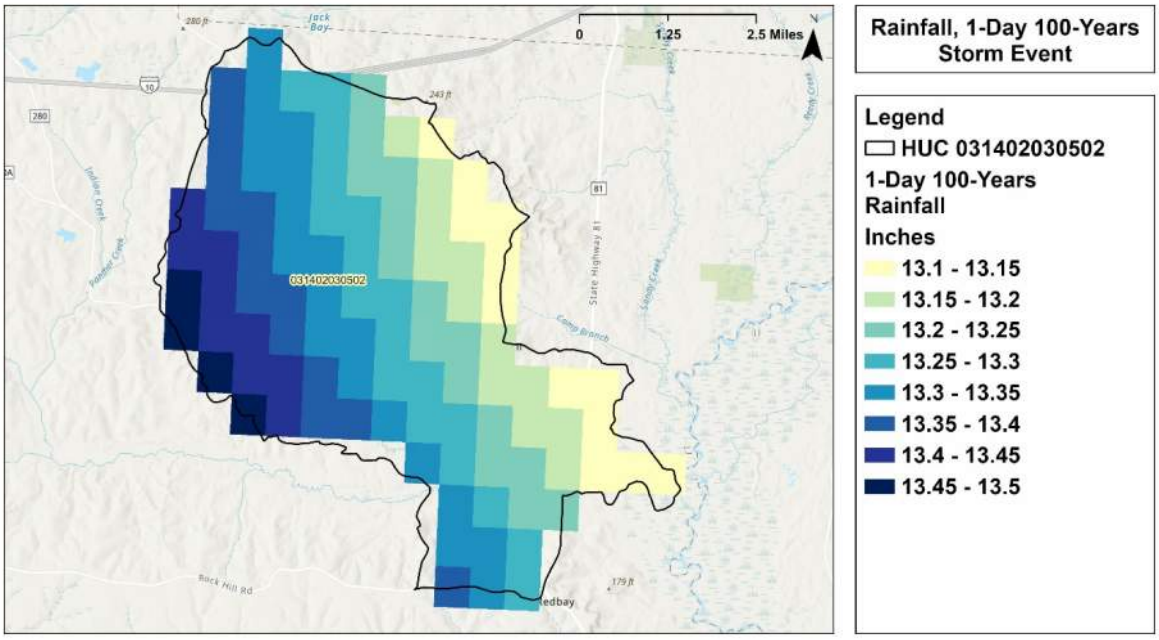

Figure 22. Rainfall distribution map across HUC 031402030502 sub-watershed, for 1-day 100-year storm event, processed by FAU.

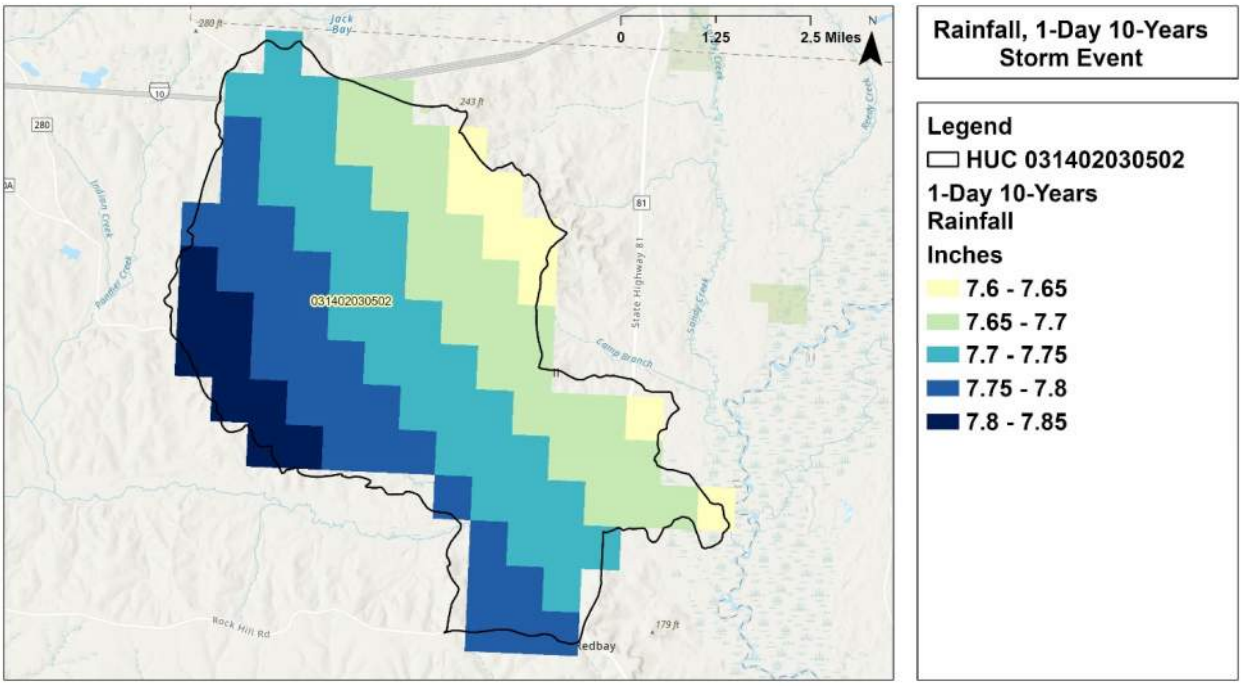

Figure 23. Rainfall distribution map across HUC 031402030502 sub-watershed, for 1-day 10-year storm event, processed by FAU.

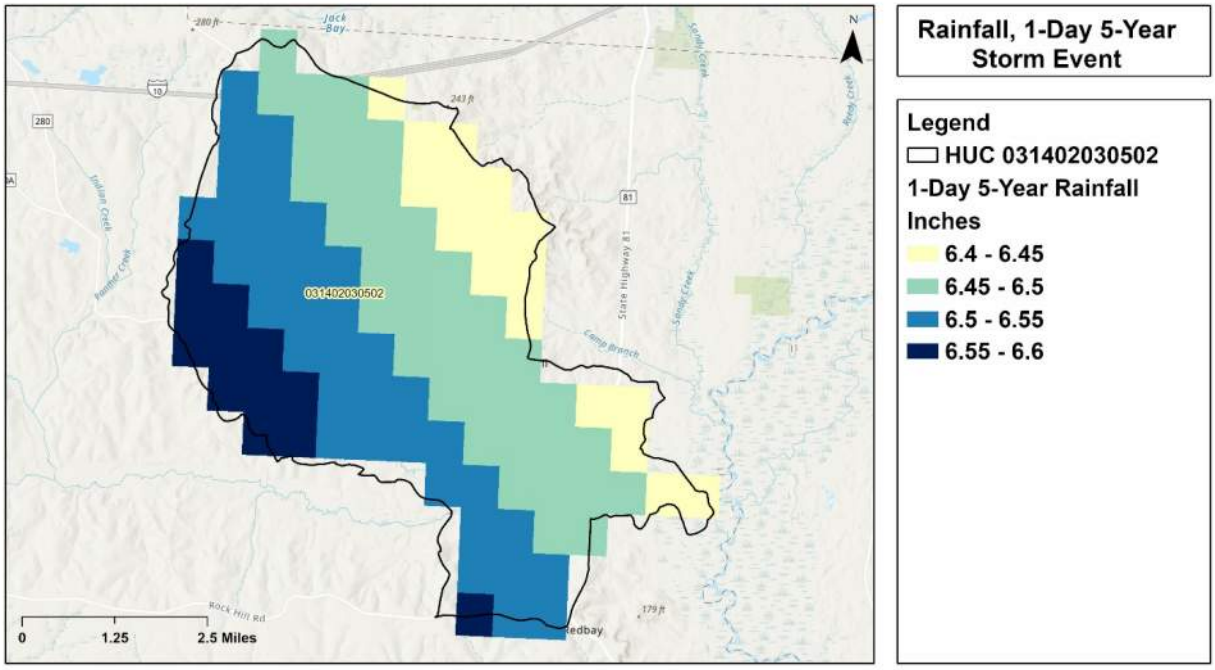

Figure 24. Rainfall distribution map across HUC 031402030502 sub-watershed, for 1-day 5-year storm event, processed by FAU.

1.7 Open Space

Open space is defined as areas that are exempted from development. Generally, this means one or more of the following qualifiers exist:

1. Land that is valuable for recreation, forestry, fishing, or conservation of wildlife or natural resources
2. Land that is a prime natural feature of the state's landscape, such as a shoreline or ridgeline
3. Land that is habitat for native plant or animal species listed as threatened, endangered, or of special concern
4. Land that is a relatively undisturbed example of an uncommon native ecological community
5. Land that is important for enhancing and conserving the water quality of lakes, rivers, and coastal water
6. Land that is valuable for preserving local agricultural heritage
7. Proximity to urban areas or areas with open space deficiencies and underserved populations
8. Vulnerability of land to development
9. Stewardship needs and management constraints
10. Preservation of forest land and water bodies that naturally absorb significant amounts of carbon dioxide

Permanent protection of sensitive areas can provide critical water quality protection and can be achieved through partnerships with landowners, municipalities, land trusts and state agencies. There is limited land in the study area that has been protected via acquisition by federal, state or local agencies, has conservation easements or is designated as wetlands or areas of critical concern. Agricultural land and other land cover will come from the land cover map (in Section 2.5). Added to this will be the water bodies discussed in Section 2.9, which serve a related condition to open space.

1.8 Impervious Areas

Impervious areas do not permit the infiltration of rainfall to groundwater, and because the water cannot infiltrate, it runs off faster. Faster runoff means that flows to water bodies and storm sewers occur faster and with higher peaks. The result is a disruption of the natural and potentially the planned hydrology. Impervious areas include pavement, buildings, and other areas that reduce runoff capacity. In other words, developed areas have much higher imperviousness than open spaces that are natural or agricultural.

The NLCD provides nationwide data on land cover and land cover change at a 30-m resolution with a 16-class legend based on a modified Anderson Level II classification system. Systematically

aligned over time, the database offers the ability to understand both current and historical land cover and land cover change to enable assessment of trends. Using the NLCD 2016 dataset, a layer was created by using only three categories out of the 13 to identify impervious areas such as primary roads in urban areas, secondary roads in urban areas, and tertiary roads in urban areas. The new layer was then converted to match the 3-meter spatial resolution from the DEM and the standard State Plane Coordinate system. **Error! Reference source not found.** shows the impervious areas derived from the NLCD 2016 as updated by the future land use map.

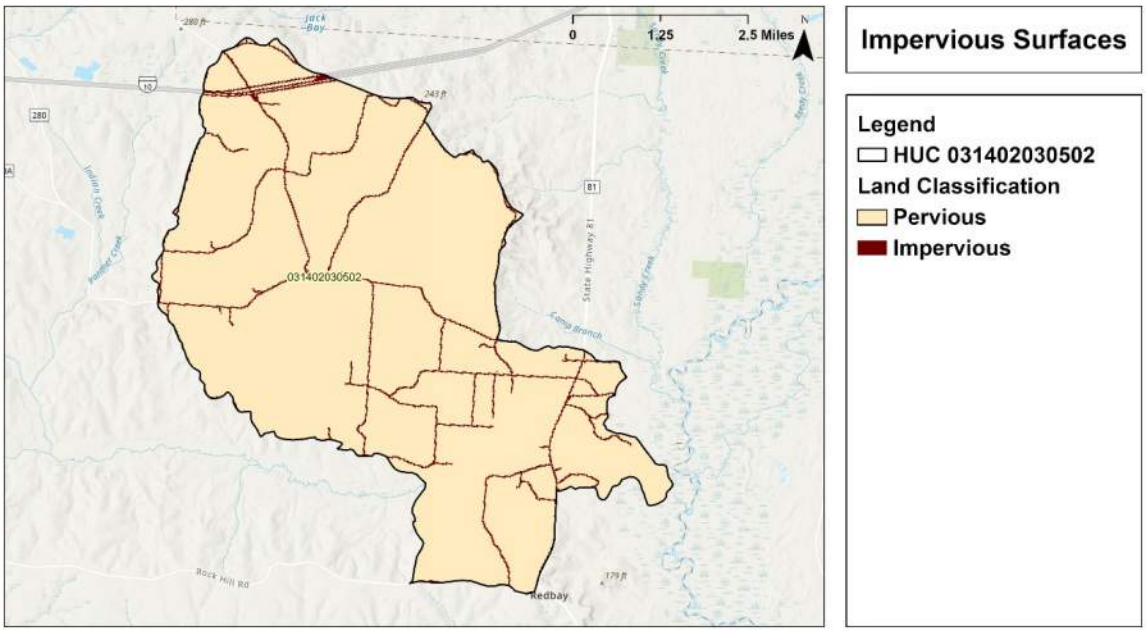

Figure 25. Impervious area map for the HUC 031402030502 sub-watershed, processed by FAU.

1.9 Water bodies

Water bodies were defined in the statewide land use land cover dataset to set soil water holding capacity to zero in model simulations (**Error! Reference source not found.**). Note that tiny water bodies may be missing from the maps. Soils were discussed previously in Section 1.4.

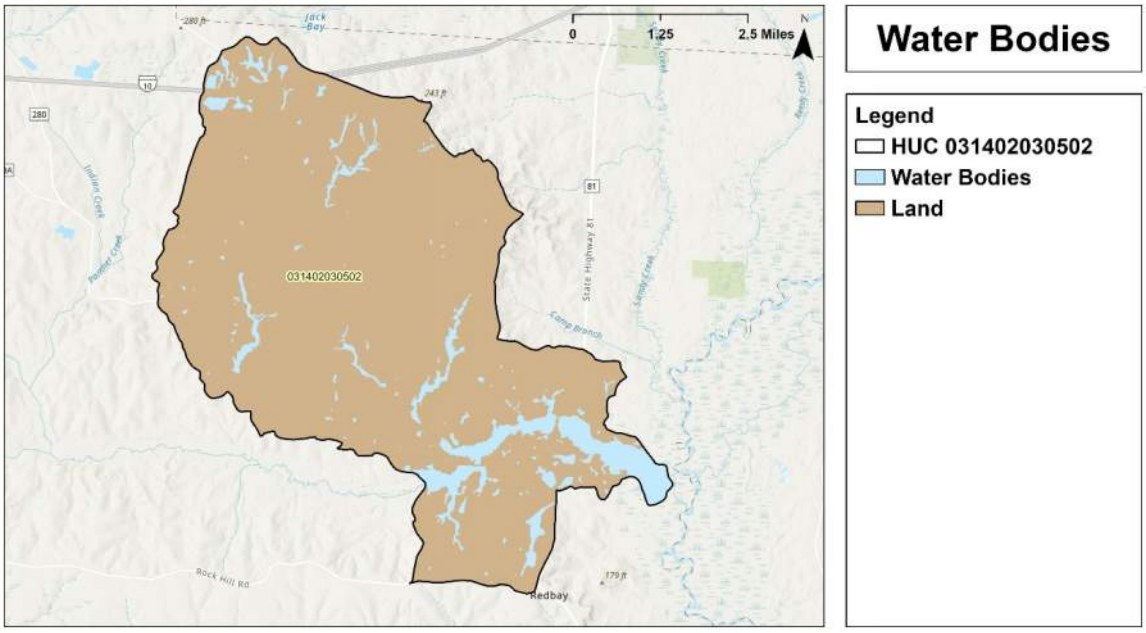

Figure 26. Water bodies map for the HUC 031402030502 sub-watershed, processed by FAU.

1.10 Natural Resources

Understanding the study area's natural resources is critical to identifying potential sources of water quality degradation and areas to designate for conservation, protection, and restoration. One possible goal of watershed master planning is to protect terrestrial wildlife, aquatic habitat, and buffer zones. USGS maintains important sources of information on physical and geographical features as well as soil and mineral resources, surface and ground water resources, topographic maps, and water quality monitoring data. The USDA's Natural Resources Inventory (NRI) (www.nrcs.usda.gov/technical/NRI) is a survey of information on natural resources on non-federal land in the United States that captures data on land cover and land use, soil erosion, prime farmland soils, wetlands, habitat diversity, erosion, conservation practices, and related items. Since 2001, the NRI has been updated continually with annual releases of NRI data from all 50 states. The information provided can be used for addressing agricultural and environmental issues down to the county or cataloging unit level. Therefore, this data can be used to determine erosion and site-specific soil characteristics for certain land uses such as croplands, pasturelands, forestlands, etc., but the data is typically provided as inventories, not GIS layers.

1.11 Demographics

Demographics data is important for determining several key indicators for watershed master planning such as the ability to pay for improvements, social justice issues, land acquisition costs, property/land use, and communication strategies. The US Census has databases at the census tract

level. Based on the census data for the study area, **Error! Reference source not found.** outlines population and racial composition demographics.

Table 5. Demographics and Housing Characteristics of Cities and Towns in Walton County.

Demographic Parameter	**Miramar Beach**	**Freeport**	**DeFuniak Springs, City**	**Paxton**	**Rosemary Beach**	**Santa Rosa Beach***	**Walton County**

*It includes the communities of Point Washington to the East and a 15-mile stretch of the Emerald Coast from the east side of Miramar Beach to the west side of Seagrove Beach and the beach communities along 30A, including Grayton Beach and Seaside.

** Census Designated Place.

1.12 Stormwater Infrastructure Inventory

Local community stormwater systems consist of drainage ditches, storm sewers, retention ponds and other facilities constructed to store runoff or carry it to a receiving stream, lake, ocean, or other waterbody. Other man-made features include yards and swales that collect runoff and direct it to the sewers and ditches. When most of these systems were built, they were typically designed to handle the amount of water expected during a 10-year storm. Larger storms overload them, and the resulting backed-up sewers and overloaded ditches produce shallow flooding. Another urban drainage problem occurs in the areas protected by levees. Being in floodplains, they are flat and do not drain naturally, especially when a levee blocks the flow to the river. To drain these areas, channels have been built and pumps installed to mechanically move the water past the levee. Often, these man-made systems do not have the capacity to handle heavy rains or intense storms.

Another challenge with stormwater infrastructure is related to recordkeeping. It is not uncommon for stormwater data to be incomplete in most jurisdictions and completely lacking in others. Quality of data differs from jurisdiction to jurisdiction; some are in GIS formats, while others are paper maps or as-builts that represent the infrastructure at a macroscale level. The condition of the assets may be lacking, and the maintenance history may not be available either. Stormwater assets may have been installed with no records, especially in rural areas, farm fields, and private property.

Walton County passed Ordinance No. 2008-06 that prohibits unauthorized discharges into storm drains or ditch systems. In addition, the Public Works Division is currently running a continuous public awareness campaign aimed at encouraging the adoption of best management practices (BMPs) for managing stormwater runoff. This initiative targets both the business community and the residents of Walton County.

To address the issue of flooding, Walton County has implemented several measures along the years, such as:

- Drainage Systems: The county has invested in the development and maintenance of drainage systems, including ditches, canals, and retention ponds, to manage stormwater runoff and reduce flood risk.
- Floodplain Management: Walton County has adopted floodplain management regulations and participates in the National Flood Insurance Program (NFIP) to encourage responsible development in flood-prone areas.
- Elevation Standards: New construction projects within flood zones are required to adhere to specific elevation standards to minimize potential flood damage.

- Emergency Response: The county has established emergency response plans to assist residents during flood events, including evacuation procedures and the provision of emergency shelters.

Key stormwater assets for the HUC and Walton County are indicated in **Error! Reference source not found.** and **Error! Reference source not found.**, respectively. Stormwater structures and management processes in the county consist of stormwater outfall, water wells, weir, pollutant control boxes, inlets catch basins, pipes culverts, ditch conveyance swales, structures, pipes and open conveyance.

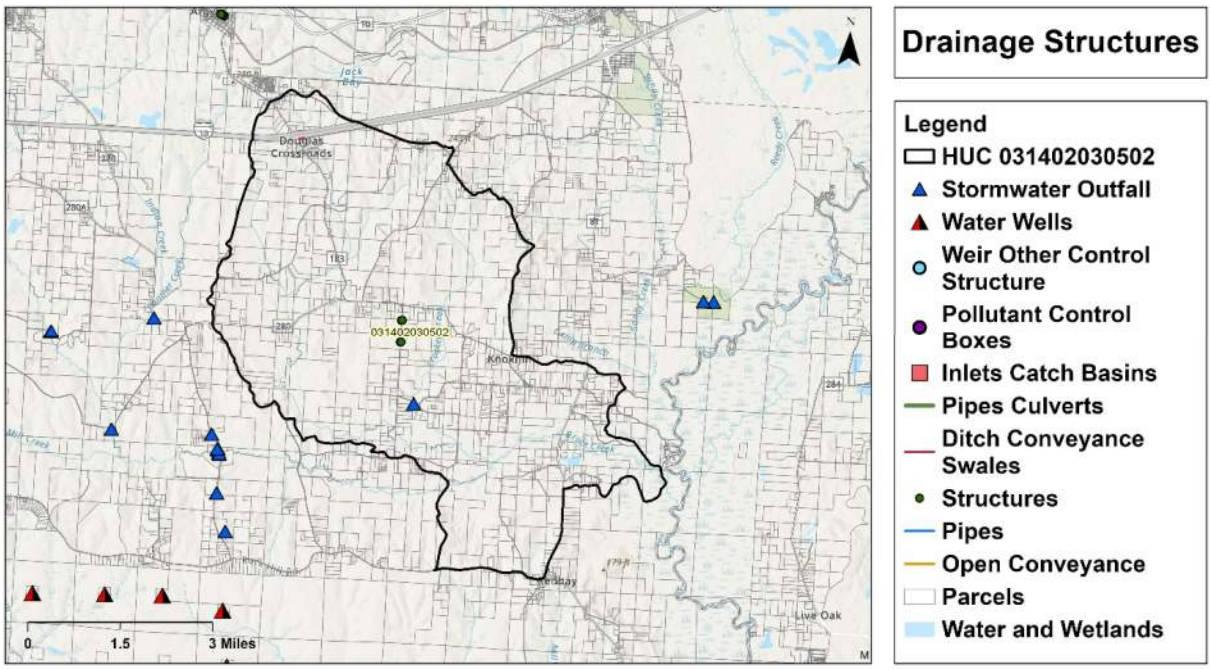

Figure 27. Stormwater Infrastructure for the HUC 031402030502. Processed by FAU.

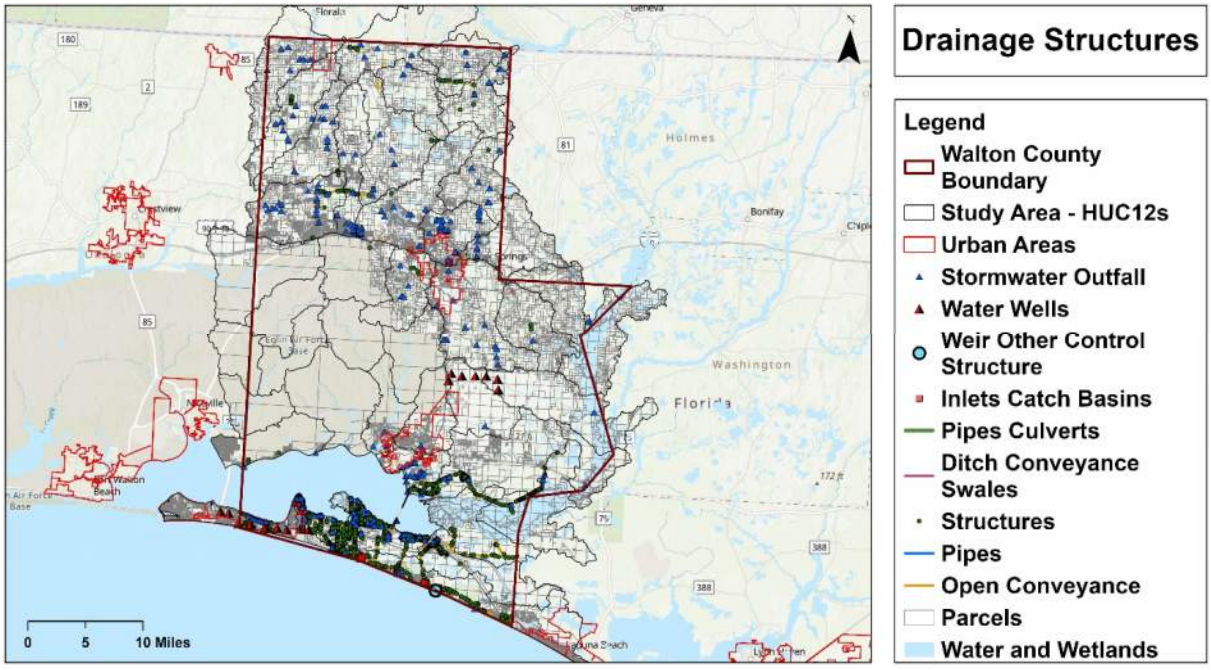

Figure 28.Stormwater Infrastructure for Walton County. Processed by FAU.

Although nature-based infrastructure might be installed, it is not certain. The stormwater system must maintain compliance with the stormwater regulations, which requires record-keeping, policy development, inspections and maintenance. The goals of such stormwater management may include:

- Best landscape practice;
- Control car washing contribution to pollution;
- Enforce the Stormwater Pollution Prevention Plan (SWPPP) by site evaluation, assessment, erosion and sediment controls, preventive maintenance, certification and inspection reporting for construction sites and city planning;
- Implement a hazardous material elimination system;
- Eliminate illicit dumping;
- Proactive and reactive catch basin inspections and maintenance;
- Street sweeping to control debris;
- Maintain swales to help prevent stormwater pollution flooding.

1.13 Data Gaps

FAU has developed comprehensive databases to address the information needed for the vulnerability assessment. These are included in **Error! Reference source not found.**. The data can be used to model the impacts of flood routing during the storm of interest. As a result, the modeling pieces (discussed in Chapter 2) will include the following:

- Flood response model results (Cascade 2001)
- Flood risk/hazard mapping
- Vulnerability assessments to identify areas of concern for future repetitive losses

There is only one data gap for the area – existing stormwater infrastructure records are incomplete. However, for the purposes of this plan, this data gap does not limit the findings as there are two scales: 1) the sub-watershed level and 2) community hotspots. A neighborhood level vulnerability assessment will require the local infrastructure inventory.

Table 6. List of datasets collected by FAU as of List of datasets collected by FAU for the project (12/20/2020)

Data Category	Dataset Name	Original Source	Spatial Coverage/ Resolution	Temporal Coverage/ Resolution	Link to the Dataset on our Server (physical location)	Dataset size and Format	Native or FAU Processed dataset

2.0 ASSESSMENT OF VULNERABLE AREAS

Defining flood risk due to compounding hydrographic influences is the central concern of this WMP. Modeling and assessment of vulnerability focused on the combination of a high-water table, heavy rains, and impervious conditions that can lead to localized nuisance flooding events. Through a previous survey with local officials, the number of days of continuous nuisance flooding that the public will tolerate before that flooding is considered destructive is about 4 days (E Science 2014).

For a large study area, small parts may actually be at risk. The point is to identify where further study might be needed. A screening tool accomplishes this goal applied to the sub-watershed scale to designate areas that are susceptible to periodic flooding events. Utilizing the information collected and analyzed in Chapters 1 and 2, and comparing to data in Chapter 3, vulnerability can be identified.

2.1 Historical and Existing Challenges

Walton County has faced various historical and existing challenges as well as natural hazards over the years. Some of these include:

- Hurricane and Tropical Storms: being situated along the Gulf Coast, Walton County is vulnerable to hurricanes and tropical storms, which can lead to damage to the built and natural environment, as well as poses risks to human and wild life.
- Coastal Erosion: The county's coastline is subject to erosion due to natural processes and human activities. Erosion can lead to the loss of beaches and threaten coastal structures and properties.
- Flooding: heavy rainfall, storm surges from hurricanes, and other factors can cause localized flooding, particularly in low-lying areas. Flood events can disrupt daily life, damage property, and impact transportation.
- Water Quality and Quantity: as in many coastal areas, managing water quality and maintaining an adequate water supply are ongoing challenges. Pollution from stormwater runoff and other sources can affect water quality, and groundwater resources need to be carefully managed to sustain the growing population.
- Wetland Loss: The county's wetlands face the threat of degradation and loss due to urban development and other human activities. Protecting these essential ecosystems is vital for maintaining biodiversity and mitigating flood risks.
- Urbanization and Development: Balancing the demand for development and growth with the preservation of natural habitats and resources is a persistent challenge. Unplanned

urbanization can lead to habitat destruction, increased runoff, and exacerbate flooding risks.

- Land Use and Zoning: Proper land use planning and zoning are essential to address issues related to population growth, infrastructure development, and natural hazard mitigation. Ensuring responsible development practices can help minimize risks.
- Invasive Species: Like many regions, Walton County faces the threat of invasive plant and animal species. These invasive species can disrupt local ecosystems, negatively impacting native flora and fauna.
- Sea-Level Rise: With rising sea levels due to climate change, coastal communities like Walton County's coastal areas are at greater risk of inundation and storm surges during extreme weather events.

The fast growth of the population and urban development in the coastal areas of the county exacerbates effort to protect open space for land percolation of water. While regulations are in place to reduce the influx of stormwater, the challenges will continue with development.

2.1.1 Existing Management Efforts in the Watershed

The county is under Northwest Florida Management District (NWFMWD) jurisdiction, which covers the Florida Panhandle region. The NWFMWD is responsible for managing and protecting water resources in its designated regions, which includes issues related to water supply, water quality, flood control, and natural resource conservation. Local governments have local stormwater utility infrastructure and planning/policy tools to reduce future flood potential. Most of the major projects to date have been focused on addressing the water quality issues and flooding due to extreme rainfall.

2.1.2 Critical Target Areas Identification

By modeling the HUC 031402030502 sub-watershed flood response to a series of rainfall events (plus king tides), and further classifying flood risk as the probability of inundation, it is possible to identify critical target areas. These areas are particularly vulnerable to flooding and are subject to further study through a scaled-down modeling approach. The screening tool is first applied at the greater watershed level to provide an initial risk assessment focused on the hydrologic response to a rainfall event given the unique characteristics and features of the sub-watershed or study area. The process is discussed later in Section 2.2 with results presented in Section 2.4.

2.1.3 Potential Preservation Areas

Walton County boasts several areas with high biodiversity value. These areas include the unique coastal dune lakes, which support diverse ecosystems and contribute to water quality along the

coast. Wetlands are crucial habitats that provide refuge for a variety of plant and animal species while acting as natural water filters. State parks like Topsail Hill Preserve and Grayton Beach State Park are valuable conservation areas with diverse coastal ecosystems. Additionally, preserving the Choctawhatchee River Basin is essential for the biodiversity of the region.

2.2 Vulnerability Maps

2.2.1 Screening Tool

The screening tool utilizes topographic data from various sources (Section 1.1), water table elevations (Section 1.2) and surface water gauges (Section 1.3) downloaded from the NWFWMD website, tidal information for coastal areas obtained from the NOAA Current & Tides website (Section 1.3), soil maps obtained from the USDA (Section 1.4), and another key dataset as described previously in Chapter 1. The design storms are discussed in Section 1.6. The reason this is critical is that to do any modeling (as required by the CRS program), a screening tool should be used to identify regions with a high risk of inundation based on multiple collected datasets and hydrological models. **Error! Reference source not found.** shows how the GIS layers interface in the tool and how they are combined for spatial analysis.

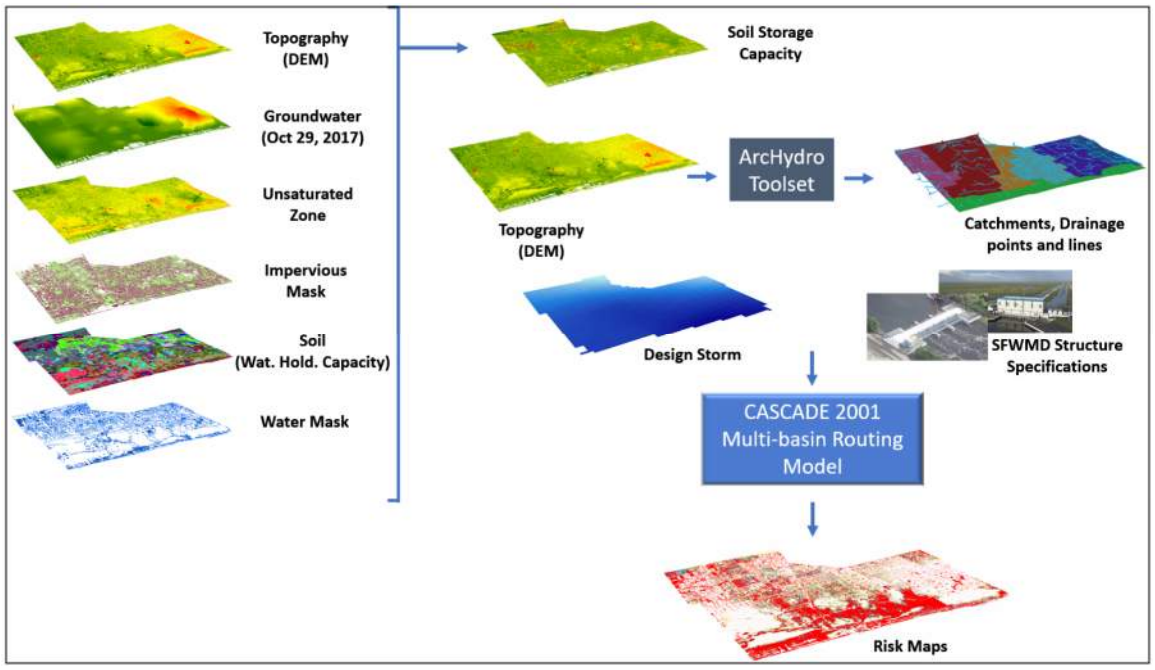

Figure 29. Screening tool methodology for creating flood risk maps.

The model chosen for this screening tool is Cascade 2001, which is a multi-basin hydrologic/hydraulic routing model developed by the SFWMD. The model permits the investigator to run different storm events to determine flooding scenarios. The boundaries are

critical for basin studies and must be chosen carefully. The following data layers collected in the prior section are processed to develop the input files for Cascade 2001:

- Topography
- Soils
- Development intensity
- Groundwater elevations
- Surface water/Outlet locations

The software creates a glass box where water rises to a certain level and then decreases. Running the simulation requires defining the basin (HUC or sub-HUC) and input of the following data:

- Area
- Portion of area above a given elevation
- Initial groundwater stage
- Longest travel time for the runoff to reach the most distance point of discharge
- Ground storage as estimated from the USDA gridded National Soil Survey Geographic Database (gNATSGO)

  Ground storage ≈ (Water holding capacity) × (Surface elevation – GW elevation)
  = 2 × (AWS for a soil layer of 0-150 cm) / 150cm × (Surface elevation – GW elevation)

- Available water storage (AWS) for a soil layer of 0-150 cm
- Average amount of precipitation that can be stored in the soil layer

The output from the model is an elevation surface that can be used to develop a flood map for the study area (**Error! Reference source not found.**), which shows the spatial distribution of probabilities of flooding during the modeled 1-day 100-year storm event.

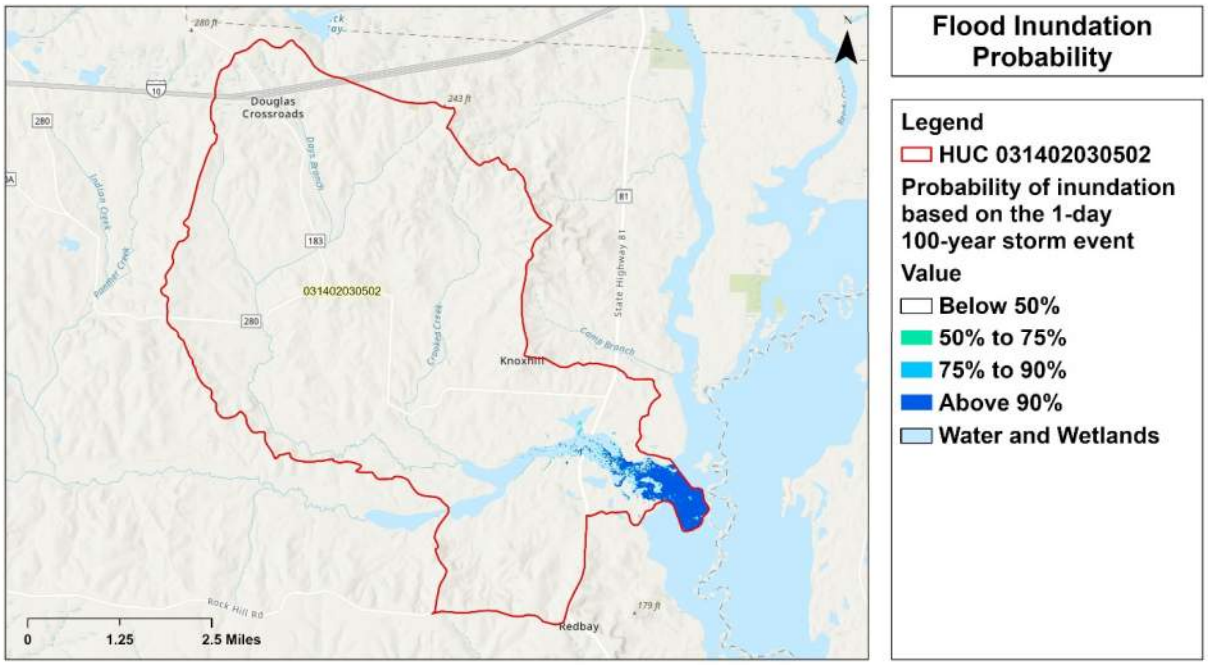

Figure 30. Probability of flood risk map during the modeled 1-day 100-year storm event for the HUC 031402030502, processed by FAU.

2.2.2 Identification of Vulnerable Areas

Given these assumptions and the Cascade 2001 outputs, the goal of this methodology is to produce a spatially-temporally quantified understanding of nuisance-destructive flood potential in the study area given observed values. Risk is a function of compounding geo-hydrological features, namely, surface water, groundwater, topography, build-out, and time of year. A GIS-based algorithm and spatial interpolation generated layers of the greatest observable hydrographic surfaces. These outputs were then compared with high resolution topographic LiDAR data to develop digital elevation models that reflect the observed risk landscape. These models can then be combined into Cascade 2001 to produce vector and volume information, in combination with soils, vegetation and impervious surfaces, allowing the observed model outputs to be extrapolated into a more predictive context.

To evaluate flood vulnerability at this scale, the analysis starts with a binary flooding surface (0 = below 50% chance of flooding; 1 = above 50% flooding) based on output from the screening tool for a specified design storm. Next, attributes of that raster based on "VALUE = 1" query are extracted using *Extract by Attributes* tool. Then the *Batch Project* tool was used to map critical facilities data to the common coordinate system (NAD83 UTM Zone 17N), unit = meters. Then a field was added using *Add Field* for [PriorityTier] = assigned Tier #1-4 value from the DOR codes and [Area_sqmeter]. The critical facilities layers were then merged into a single layer to calculate

the polygon geometry for [Area_sqmeter] using the *Merge* tool. Next, *Zonal Statistics as Table* is used to calculate the SUM of flooded values ("VALUE = 1") within each critical parcel. Output table has fields for SUM (i.e., total # of flooded pixels per critical parcel) and AREA in map units of square meters (since each pixel in the flooding surface has a cell size of 3-meters by 3-meters, each area is equal to the SUM value multiplied by 9 m^2). Using the *Join Field* tool, the SUM and AREA fields are joined to the merged critical facilities layer based on a key attribute, first renaming these fields for clarity (e.g., AREA_FLOODED_3d25y). Once all field data is included, the next step involves using *Export Table* to export the dataset as a CSV file. Note that non-flooded parcels have zero flooded area, so they receive a <Null> value from the zonal statistics tool. To replace null values with zeros, we use *Calculate Field* in the attribute table along with the following Python expression (replacing the respective field name): "0 if !AREA_FLOODED_3d25y! is None else !AREA_FLOODED_3d25y!". Next, the CSV file is saved as an Excel Workbook (.xlsx). The Range is converted to an Excel Table, and the columns are rearranged in the desired order. Finally, the "percent-flooded" columns are calculated as follows:

- PCT_FLOODED_3d25y = ([@[AREA_FLOODED_3d25y]]/[@[TotalArea_sqmeter]])*100
- PCT_FLOODED_1d100y = ([@[AREA_FLOODED_1d100y]]/[@[TotalArea_sqmeter]])*100

After this calculation, the table is sorted to show the higher priority tiers and higher percent-flooded values first. To reduce the number of critical facilities shown in the final table, a filter was created to show only critical facilities with 10% or more flooded area in the parcel during both storm events. Records with duplicate parcel ID numbers were removed from the table. The results of this procedure are discussed in Section 5.2 of this document.

With respect to dams and levees, for purposes of the NFIP, FEMA only recognizes systems that meet, and continue to meet, minimum design, operation, and maintenance standards that are consistent with comprehensive floodplain management criteria. The Code of Federal Regulations, Title 44, Section 65.10 (44 CFR 65.10) describes the information needed for FEMA to determine if a levee system reduces the risk from the 1% annual chance flood. FEMA has accredited levees and Provisionally Accredited Levees (that have a specified timeframe to obtain the necessary data to confirm the levee's certification status). If a levee system no longer meets Section 65.10, FEMA will de-accredit the levee system and issue an effective FIRM showing the levee-impacted area as a SFHA. FEMA coordinates its programs with USACE, who may inspect, maintain, and repair levee systems. USACE has authority under Public Law 84-99 to supplement local efforts to repair flood control projects that are damaged by floods. Like FEMA, USACE provides a program to allow public sponsors or operators to address levee system maintenance deficiencies. Failure to do so within the required timeframe results in the levee system being placed in an inactive status in the USACE Rehabilitation and Inspection Program. Levee systems in an inactive status are not

eligible for rehabilitation assistance under Public Law 84-99. There are no levees/dams listed in the sub-watershed study area.

2.3 Modeling Results

Error! Reference source not found. to **Error! Reference source not found.** are a series of maps that depict risk of flooding in the basin based on the following scenarios:

1. 3-day 25-year storm event. Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (**Error! Reference source not found.**)
2. 1-day 100-year storm event. Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (**Error! Reference source not found.**)
3. 1-day 10-year storm event. Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (**Error! Reference source not found.**)
4. 1-day 5-year storm event. Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (**Error! Reference source not found.**)

In all storm event scenarios, a moderate amount of flooding is noted at the creek entrance to the HUC. As this basin is not connected to the ocean and its altitude is above 20 feet, the HUC is expected to remain unaffected by sea level rise, therefore SLR scenarios were not computed.

The design storm simulation determined that approximately 1.88% of the HUC total area or 0.56 mi² has a probability of inundation above 50% for all four design storms. **Error! Reference source not found.** compares the four storm events.

Table 7. HUC 031402030502 expected inundated area by storm event.

Storm Event	Area with probability of inundation below 50% (Sq Mi)	Area with probability of inundation above 50% (Sq Mi)	Area with probability of inundation below 50% (%)	Area with probability of inundation above 50% (%)
3-day 25-year	28.94	0.56	98.12%	1.88%
1-day 100-year	28.94	0.56	98.12%	1.88%
1-day 10-year	28.94	0.56	98.12%	1.88%
1-day 5-year	28.94	0.56	98.12%	1.88%

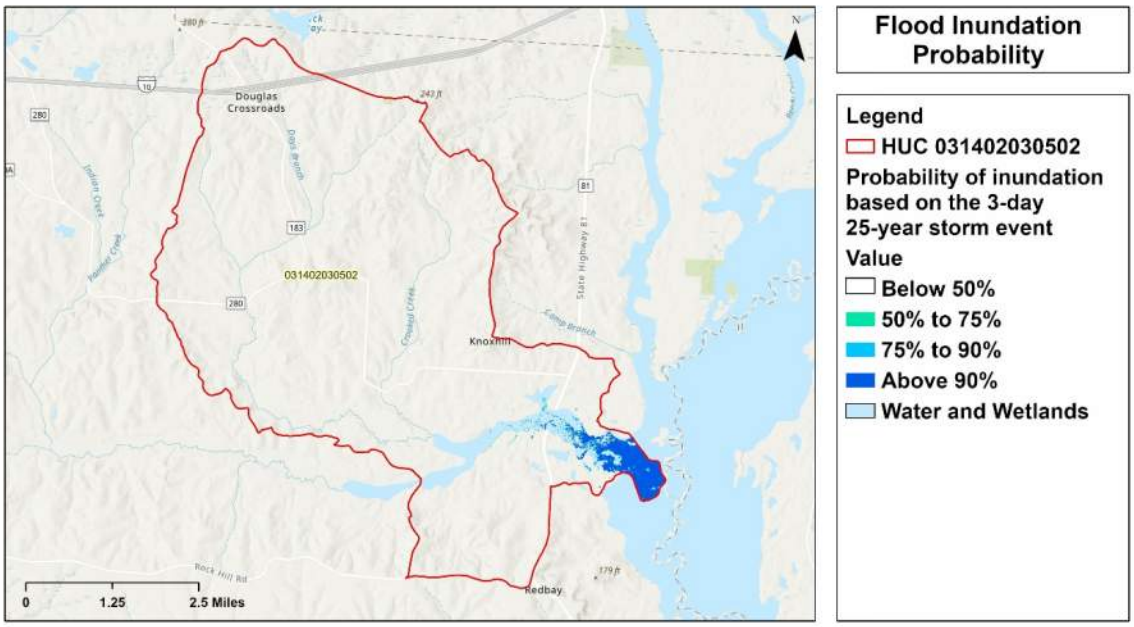

Figure 31. 3-day 25-year storm event for HUC 031402030502 sub-watershed.

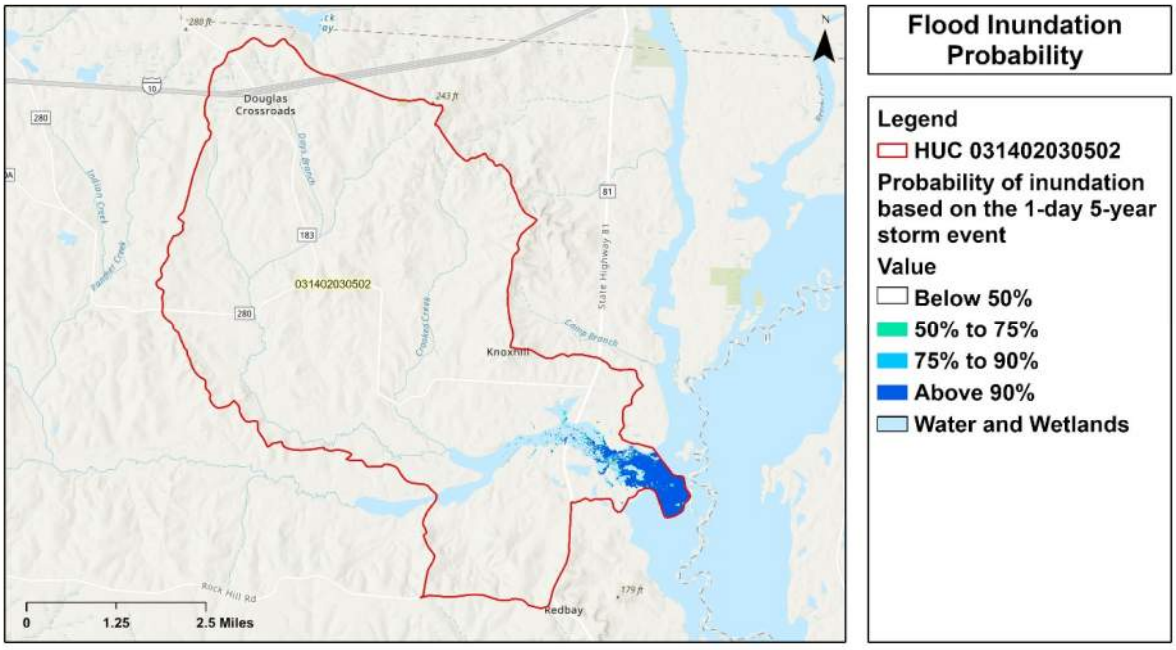

Figure 34. 1-day 5-year storm event for HUC 031402030502 sub-watershed.
Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations.
Processed by FAU.

2.4 Risk and Vulnerability

The screening tool modeling exercise from the prior section identified areas within the communities that are vulnerable to flooding. Higher priority concerns should be those properties or assets that are considered essential and need to be kept in service during a flooding event. All other improvements are local. To help with prioritization, the following is suggested:

- Tier 1 - Critical facility protection (water/sewer utilities, public safety, hospitals, schools, power, shelters)
- Tier 2 - Essential facilities (groceries, pharmacies, roadways)
- Tier 3 - Economic centers (protecting jobs)
- Tier 4 - At risk communities
- Tier 5 - Other urban/suburban property
- Tier 6 - Agriculture/public property/vacant/undeveloped

Error! Reference source not found. outlines the priority of land use based on DOR land use codes from the property appraiser's office and assigns an associated priority level to each parcel. Note that for residential property, identifying at-risk communities (income, age, disability, health) requires a further drilldown to the neighborhood level (i.e. wealthy neighborhoods with few older, poor health individuals would have a lower priority than at risk communities, which generally have lower value housing and denser development). In the latter case, more people are impacted, and those people have less ability to mitigate risk. Based on these priorities, the relative risk priority DOR land use codes were evaluated based on a scale of 1 to 6, where 1 is higher priority (more vulnerable) and 6 is the least priority (least vulnerable).

Table 8. Priority of Land Use based on (DOR) land use codes. Processed by FAU.

103	Parcels With no Values (Rail)	2

Having assigned the risk priority from 1 to 6 in the DOR codes and the percentage of the parcel that floods during the applicable design storm, properties that are more critical to the function of the community can be identified. The methodology is to first convert the DOR code priority tier to its inverse scale by the following equation:

Consequence of risk factor = 7 – DOR Code Priority Tier

The flood risk factor from the screening tool is interpreted based on flooding probability. We take all parcels in tiers #1-4 that have a greater than 50% chance of flooding during a particular design storm and calculate the percent of the parcel that would flood during that event. The percentage is converted to a 6-point scale termed as the Flood Risk Factor, shown in **Error! Reference source not found.**.

Table 9. Flood Risk Factor Classification.

Percent of Parcel Flooded	Flood Risk Factor
90-100%	6
80-89%	5
70-79%	4
60-69%	3
50-59%	2
<50%	1

The priority is further developed by assigning 75% of the importance to the consequence of flooding and 25% importance to flood risk, or three times the importance to the consequence of flooding to come up with a composite score as follows:

Flood Risk Factor × 25% + Consequence of Risk Factor × 75% = Composite Score

Example: 1 × 25% + 6 × 75% = 4.75

Those higher priority properties that received the higher composite score are where the mitigation strategies and financial resources should focus first.

2.4.1 Results

Error! Reference source not found. and **Error! Reference source not found.** depict the HUC 031402030502 sub-watershed priority of land uses showing the critical facilities that should receive priority. The first map (**Error! Reference source not found.**) exclusively displays critical facility parcels within the HUC without any flooding. The second map (**Error! Reference source not found.**) overlays critical facilities onto the 1-day 100-year storm event scenario. **Error! Reference source not found.** is a mosaic showing critical facilities overlaid in the 1-day 100-year storm event for the whole county.

Additionally, **Error! Reference source not found.** illustrates the composite score based on 1-day 100-year storm event for the HUC, which is the result of the calculations explained above, pinpointing parcels that should be prioritized. It considers only parcels classified as 1 to 4 tiers, and within the 50% probability of inundation area. Lastly, **Error! Reference source not found.** is a mosaic showing the results for composite score overlaid in the 1-day 100-year storm event for the coastal area of Walton County. As the subwatershed is not coastal, the results based on 5 ft. SLR + 1-day 100-year storm event were not computed for the basin.

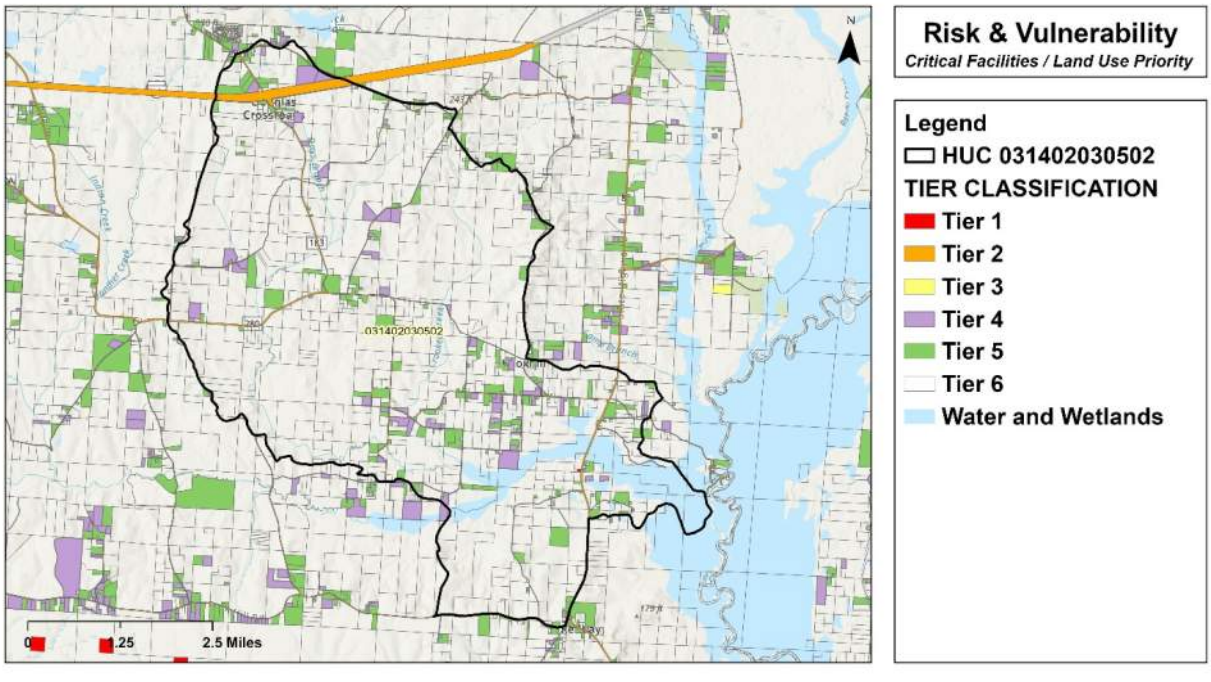

Figure 35. HUC 031402030502 sub-watershed Critical Facilities (priority of land uses) map. Processed by FAU.

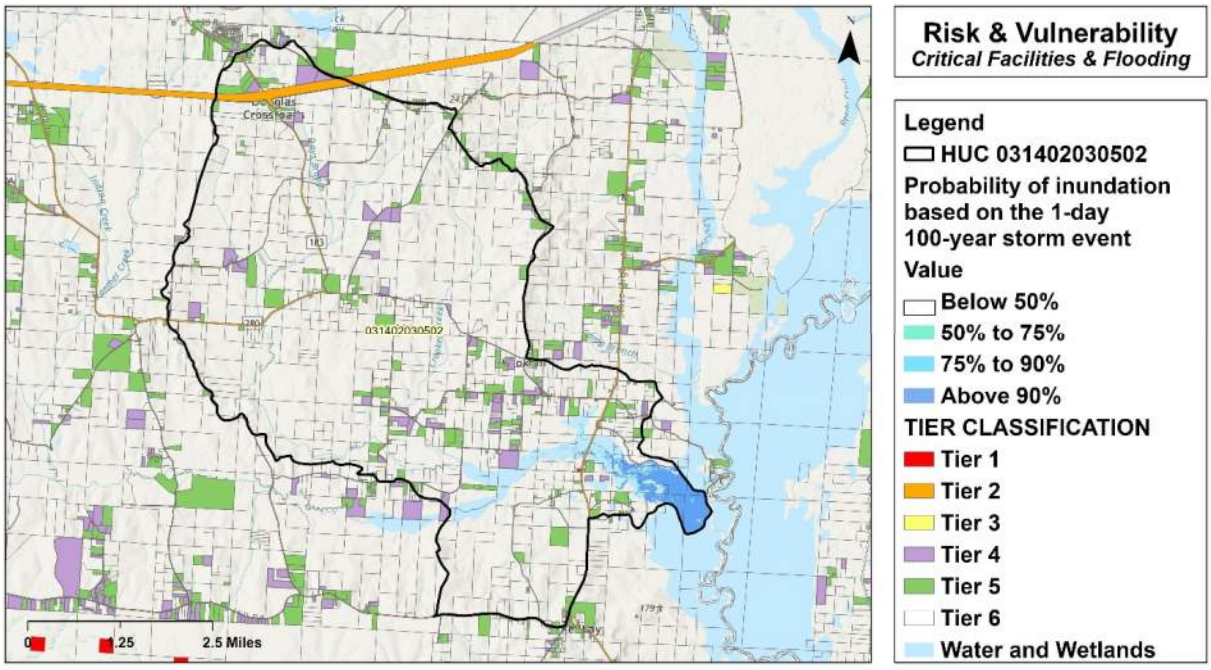

Figure 36. HUC 031402030502 sub-watershed Critical Facilities (priority of land uses) map overlaid on the 1-day 100-year storm event probability of inundation. Processed by FAU.

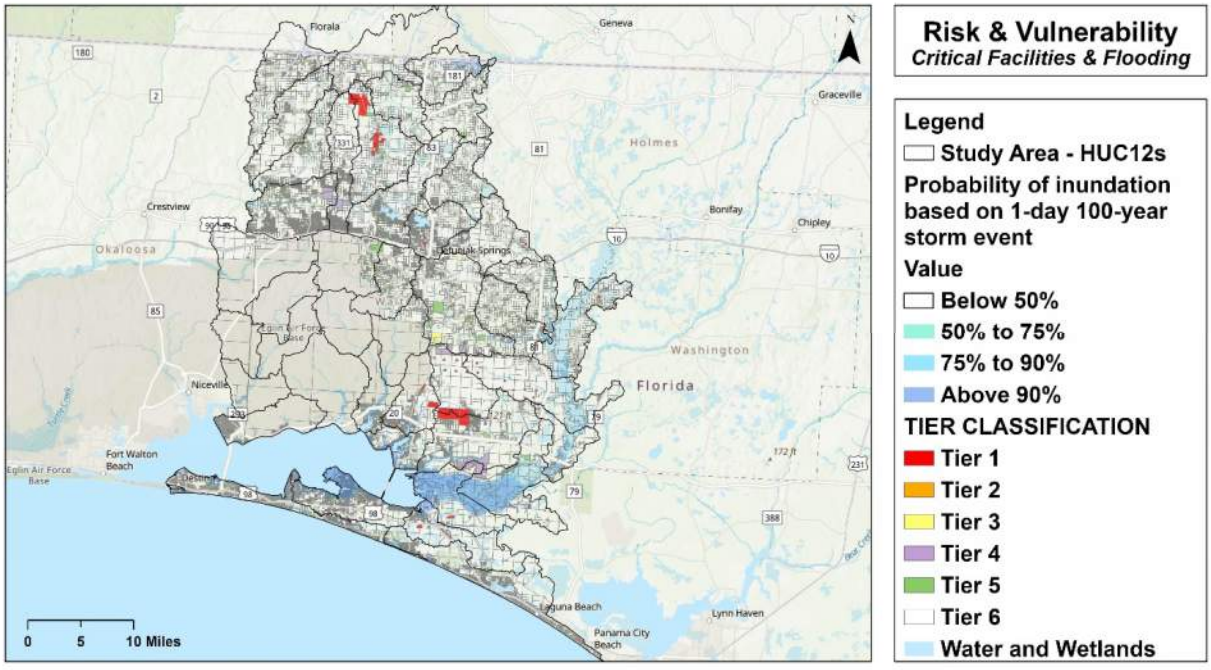

Figure 37. Walton County (mosaic) - Critical Facilities (priority of land uses) map overlaid on the 1-day 100-year storm event probability of inundation for Walton County. Processed by FAU.

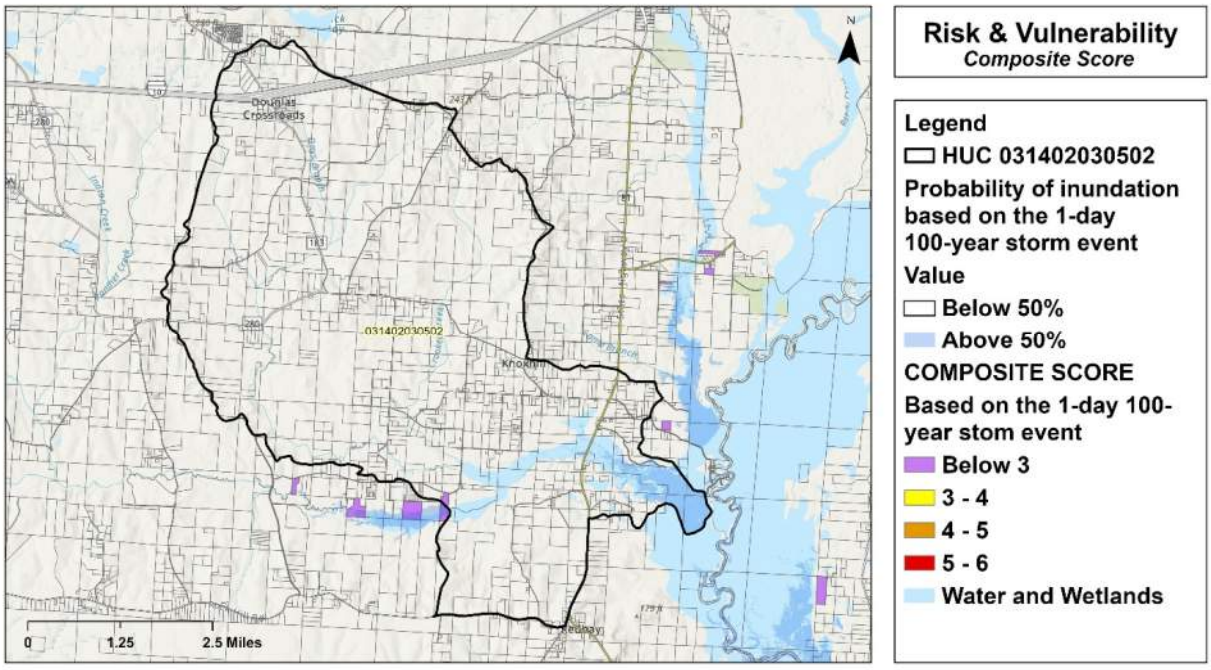

Figure 38. HUC 031402030502 sub-watershed Composite Score Risk map, with calculation based on 1-day 100-year storm event. Processed by FAU.

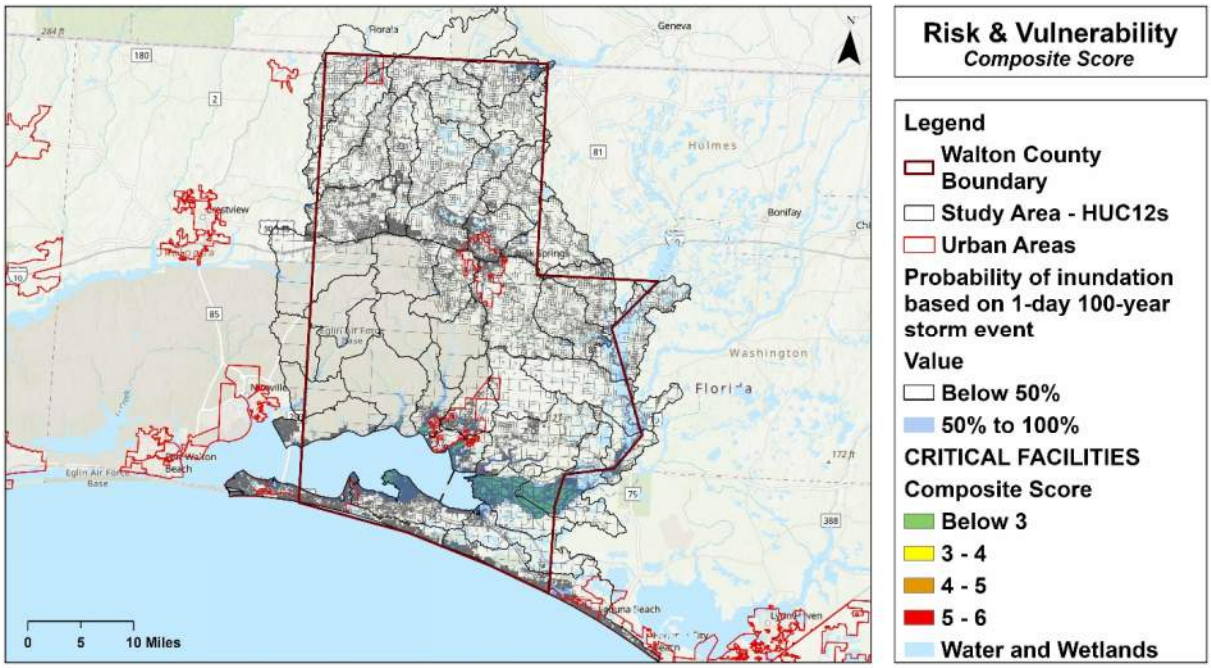

Figure 39. Walton County (mosaic) - Composite Score Risk map overlaid on the 1-day 100-year storm event probability of inundation. Processed by FAU.

Please note that due to the scale of the map, the composite score layer is not properly visible in this map.

Please note that the composite score results display outcomes exclusively for parcels within the flooding path area. Consequently, for parcels outside this flooding path, the composite results will be null. The composite score combines the flooding path area with the land use priority results to identify the most vulnerable areas deserving of priority.

2.4.2 Solutions

Chapter 5 of the Watershed Master Plan for Walton County describes a list of possible gray and green stormwater strategies to combat flooding that can be implemented as solutions for the county. The same solutions can also be applied at the HUC level, including HUC 031402030502. A summary of these flood mitigation strategies is listed in table 9. For more detailed information, please see Chapter 5-5.3 (Solutions).

Table 10. List of possible gray and green stormwater strategies to combat flooding

Strategy Class	Implementation Strategy	Applications	Benefits	Cost	Barriers to Implementation
Green	Rainwater harvesting	Local, small scale, easily implemented in developed areas	Protects property, treats runoff	Under $5,000	Limited volume disposed of, so many are needed, maintenance
Gray	Pervious paving	Parking lots, patios, driveways, anything except paved roads due to traffic loading	Reduces roadway and parking lot flooding	$10-20/sf, requires bumpers and sub-base to maintain paver integrity	Must be maintained via vacuuming or the perviousness fades after 2-3 years
Green	Detention	Common for new development, but difficult to retrofit; limited to open areas	Removes water from streets, reduces flooding	$200K/ac	Land availability, maintenance of pond, discharge location Uses up land that could otherwise be developed
Gray	Exfiltration Trench	Any low-lying area where stormwater collects and the water table is more than 3 ft below the surface; densely developed areas where retention is not available, roadways	Excess water drains to aquifer, some treatment provided	$250/ft	Significant damage to roadways for installation, maintenance needed, clogging issues reduce benefits
Gray	Central sewer installation	All areas where there are septic tanks. Mostly a water quality issue	Public health benefit of reducing discharges to lawns, canals, and groundwater from septic tanks	$15,000 per household	Cost, assessments against property owners, property rights issues

Strategy Class	Implementation Strategy	Applications	Benefits	Cost	Barriers to Implementation
Green	Flood prone property acquisition	Regional agency - could be any low-lying areas	Removes flood prone areas from risk	$2K-$100K/ac depending on whether it is already developed	Difficult to implement if occupied, issues with willing sellers, cost, lack of funds for acquisition
Gray	Pump stations	Any low-lying area where stormwater collects, and there is a place to pump the excess stormwater to such as a canal; common for developed areas	Removes water from streets, reduces flooding	Start at $1.5 to 5 million each, number unclear without more study	NPDES permits, maintenance cost, land acquisition, discharge quality
Gray	Armored sewer systems	Any area where gravity sanitary sewers are installed	Keeps stormwater out of sanitary sewer system and reduces potential for disease spread from sewage overflows	$500/manhole	Limited expense beyond capital cost
Gray	Sea walls	Barrier islands and downtown coastal areas	Protects property	$1200/ft	Private property rights, neighbors
Policy	Changes in land use	Applicable universally	Achieves flood risk mitigation by adjusting permitted land use	Low but may incur private property rights conflicts and litigation	Private property rights conflicts and litigation
Gray	Roadway base protection	Low-lying areas, coastal communities	Protects roads and access routes	$1 million per lane-mile	Cost, adjacent properties become uninsurable
Policy	Enhanced elevation of buildings	Developers would implement this for new construction	Reduced flood risk	Varies	Potential issues with building structure or latticework, and existing homes that are not elevated

2.4.3 Impacted Adjustment Areas

In the evaluation of flood risk management strategies within the framework of the National Flood Insurance Program Community Rating System (CRS), the concept of impact adjustment plays a pivotal role in determining the extent to which CRS-credited activities or elements influence the vulnerability of a community's Special Flood Hazard Area (SFHA) and the structures located within it. It's important to note that while the usual results of impact adjustment are related to the SFHA area, in this specific analysis, it was used 1-day 100-year storm event inundation area performed by FAU instead.

In this context, the following table presents a breakdown of the impact adjustment calculations for a 1-day 100-year storm event inundation. The values are expressed in acres and depict the areas of interest as well as the deductions considered in the evaluation process.

The outcomes of these calculations provide valuable insights into the impact adjustment scenarios:

With ALL State Lands:

This scenario reflects the remaining inundation area after accounting for deductions A, B, and C. It represents the effect of CRS-credited activities without considering the influence of state lands in managing flood risks.

With NO State Lands:

In this case, the remaining inundation area is determined by considering all deductions, including state lands (both open space and not open space – see **Error! Reference source not found.**).

These calculations highlight the dynamic nature of impact adjustment within the CRS framework. By accurately gauging the influence of individual elements, the system ensures that credit allocations align closely with a community's efforts in flood risk mitigation.

Table 11. Impacted Adjustment Areas for HUC 031402030502. Processed by FAU.

AREAS	**ACRES**
HUC-12 Sub-watershed: 031402030502	18879.32
All of the 1-day 100-year storm event inundation	**355.77**
Subtract	
A. Bodies of Water in 1-day 100-year inundation > 10 acres	335.50
B. Federal Land in 1-day 100-year inundation > 10 acres	0.00
C. Reservation/Tribal Land in 1-day 100-year inundation > 10 acres	0
D. State Land in 1-day 100-year inundation > 10 acres that is open space	14.55
E. State Land in 1-day 100-year inundation > 10 acres that is NOT open space	0.00
The remainder is either:	
With ALL State Lands: All of the 1-day 100-year inundation minus (A+B+C) or	20.27
With NO State Lands: All of the 1-day 100-year inundation minus (A+B+C+D+E)	5.72

2.4.4 Repetitive Loss Property Map

A Repetitive Loss (RL) property is a building that has had two or more loss or damage due to a specific hazard, such as floods, hurricanes, or other natural disasters, over $1,000 each, paid by the National Flood Insurance Program (NFIP) within any ten-year period since 1978. There are more than 122,000 RL properties in the nationwide (FEMA, 2005).

These data are essential for assessing the vulnerability of certain areas to recurrent losses and for developing strategies to mitigate the risks. However, due to privacy concerns, the data cannot be openly shared with the public. For this reason, the data were converted into a hot spot analysis map. These maps, instead of identifying the specific location of the repetitive loss properties, highlight clusters of repetitive loss claims and areas where the probability of repetitive losses is higher than would be expected by random chance. In other words, it helps pinpoint locations that have a higher concentration of properties prone to repetitive losses. **Error! Reference source not found.** indicates the results from hot spot analysis in point data, showing aggregated counts, and raster data, showing the estimated probability of repetitive loss.

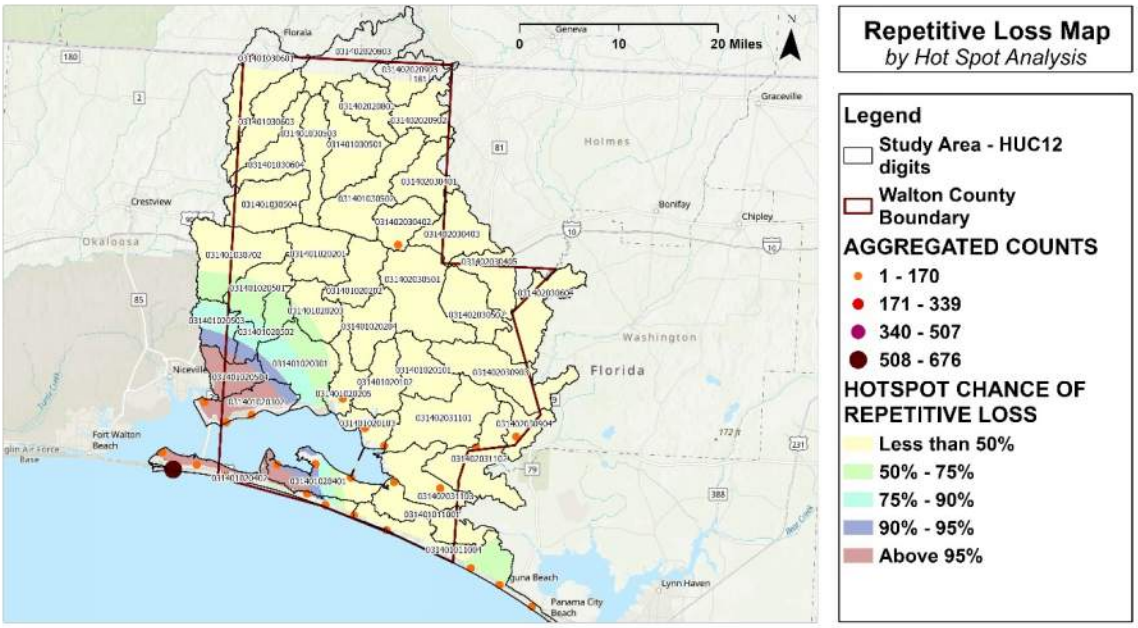

Figure 40. Repetitive Loss map for Walton County by Hot Spot Analysis. Processed by FAU.

2.4.5 Priority Projects

Although there are a good amount of parcels falling within tiers classification 1 to 5 priority of land uses, only a few of them are within the flooding zone, once flooding in the area is relatively minor and not alarming. Consequently, when considering the composite score, it is notable that most of the results are null. There are only six exceptions within the basin: five roads (Walton Bridge Rd, Sandy Creek Landing Road, Highway 81, River Rd, and Camp House Landing Rd) within score 3-4, and one mobile home, with score below 3.

X.0 EXECUTIVE SUMMARY

The goal of the appendices to the watershed plan are to outline the issues associated with the individual HUC12s that contribute or impact the community's flood vulnerability and there for its flood protection efforts. Floodplain analysis includes developing a watershed model and identifying associated inundation polygons. It builds upon information generated from the watershed evaluation so that planning and management decisions can be formulated.

This appendix describes the issues and modeling associated with one of the HUC12s that affects Walton County. In developing the County-wide plan, this HUC 12 was analyzed so as to determine how it brings or removes floodwaters from the County. For the NFIP process the goal is to analyze all communities at the HUC12 level. From a community perspective the HUC12 is less useful to residents than a community-wide plan. Hence in all cases the HUC12 results were mosaicked into the community-wide plan. Details can be found in the HUC12 appendices, some of which were brought into the community plan.

To reduce redundancy, information of the plans, ordinances, policies and regulations were rolled up to the community-wide plan and will not be repeated in the appendices. Likewise, the community wide mapping was parced for HUC12 use.

1.0 WATERSHED CHARACTERIZATION

In this section, key aspects of the watershed are characterized. This is important for later being able to identify the most vulnerable areas and to mobilize resources to implement an action plan. Understanding the characteristics of the watershed involves gathering existing information and data sets from previous planning efforts. It is important to note that this step is iterative and ongoing as new data are generated and projects are implemented and monitored.

To assess the historical and current conditions of the study area, the following existing data sets that characterize the physical and natural features of the watershed were obtained for each HUC-12 sub-watershed in the study area:

- Topographic data (LiDAR)
- Relevant waterway locations
- Groundwater levels
- Soils data
- Land uses including vacant land, wetlands, impervious, etc.
- Precipitation records
- Catchment delineations for flood routing

In addition, the FEMA flood maps must be obtained, and the storm of interest must be identified for screening purposes (1-day, 2-year, 5-year, and 100-year events as well as the 3-day 25-year storm event to achieve class 4 in the CRS Manual). In developed areas, many sources of data are already available – the key is putting the key datasets in a format that can queried for screening to identify the priority areas of the watershed. Table 6 is a summary of datasets available at cwr3.fau.edu that were used to construct this plan.

This watershed master plan is a drilldown of the larger Walton County TMDL region, which involves 42 HUC 12-digit sub-watersheds (**Error! Reference source not found.**). **Error! Reference source not found.** shows Walton County Drainage Network and the location of urban areas (cities and towns). In **Error! Reference source not found.**, the HUC-12 digits (031402030604) is highlighted among all the HUCs to help identifying its location. (Figure 3).

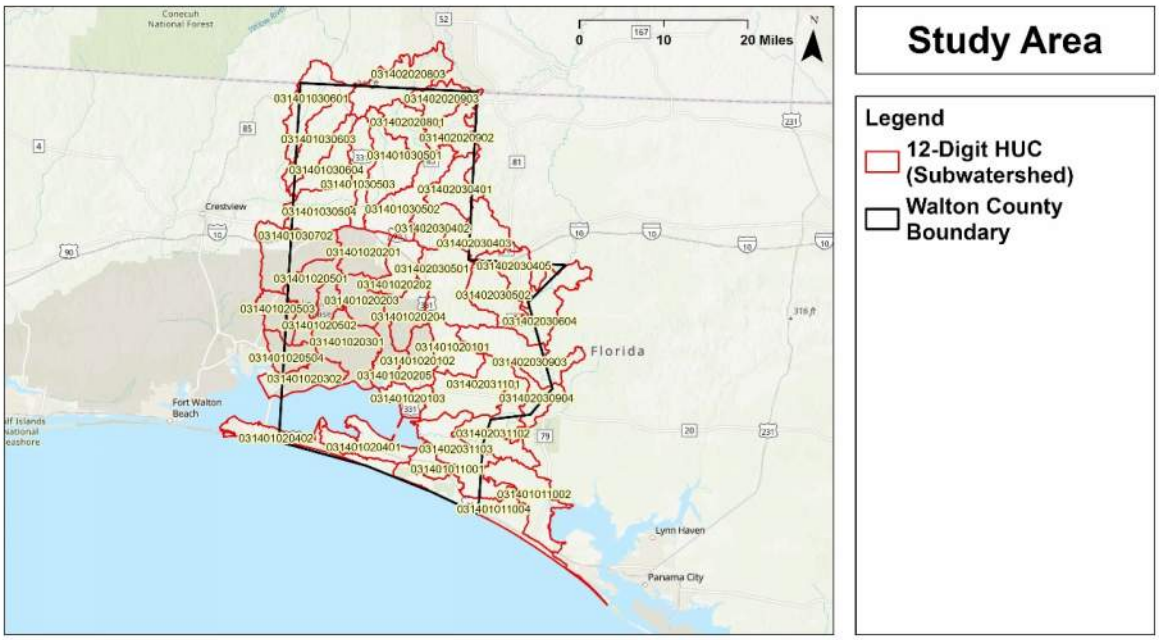

Figure 1. Walton County and all HUCs 12-digit sub-watershed, processed by FAU.

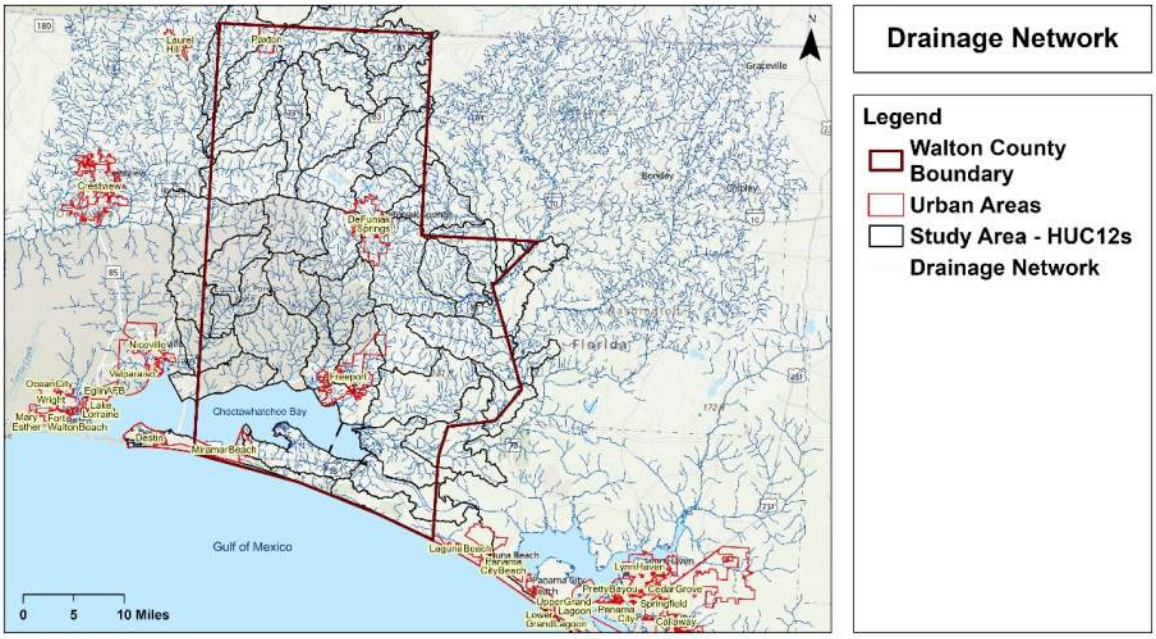

Figure 2. Walton County Drainage Network and urban areas (cities and towns), processed by FAU.

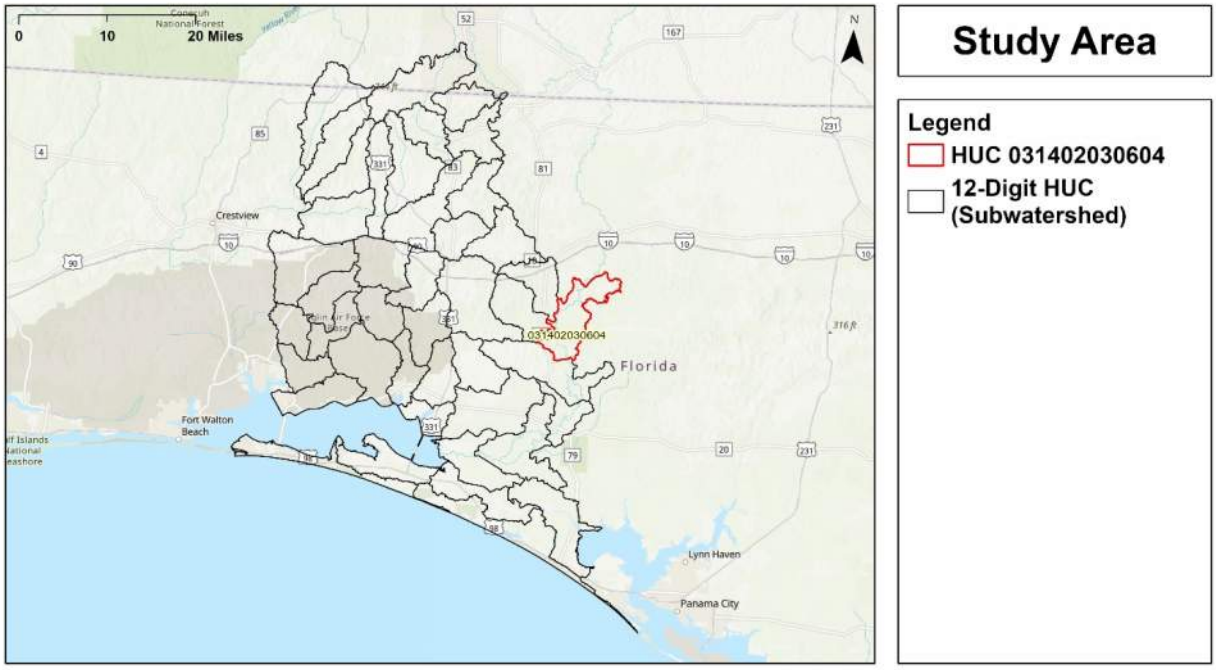

Figure 3. HUC 031402030604 sub-watershed location.

Located in the northwestern region of Florida, Walton County has 1,037.7 square miles of land and it is the 12th largest county in Florida by area, while also sits the highest point in the state, with a height of 345 feet in its northern end. With a population of 75,305 residents according to

the 2020 census and an estimate population in July of 2022 of 83,304, the county has experienced consistent growth within the past several years, driven by factors such as tourism, retirement migration, and regional population dynamics. The county was the residence for 55,043 people according to Census 2010, which leads to a percent change of 36.8% in 10 years, between 2010 and 2020, and a percentage change of 10.6% in two years, between 2020 and 2022 (United States Census Bureau).

The surge in population, particularly in the southern part of Walton County, has resulted in a corresponding expansion of infrastructure to cater to the growing needs. Essential facilities such as potable water systems, wastewater treatment plants, electrical utilities, roads, and schools have been developed to support this increasing population. However, the infrastructure expansion has brought about a significant change in the natural environment. Prior to the existing development , tropical cyclone impacts would be mitigated by natural barriers such as vegetated sand dunes, wetlands, and deserted beaches, which would absorb some of the destructive forces. Now, with the proliferation of costly infrastructure and residential dwellings in coastal areas, these storms pose a higher risk of potential damage. The very areas where development is occurring are becoming more vulnerable to the impact of severe storms, highlighting the importance of considering and implementing adequate measures to address potential storm damage in these coastal regions (Walton County Local Mitigation Strategy Plan, 2015).

Demographically, Walton County presents a heterogeneous age distribution, encompassing a blend of younger and elderly cohorts. The median age of approximately 44 years reflects the presence of both younger families and retirees seeking a serene and picturesque environment. Ethnically, the county' population is predominantly White with smaller yet notable populations of Hispanic/Latino, African American, and other racial/ ethnic groups.

Economically, the tourism sector stands as a dominant force in Walton County, constituting 23.4 percent of the workforce, according to Walton County Economic Development Alliance in 2011, due to its renowned beach destinations, such as Santa Rosa Beach, Miramar Beach, and the New Urbanist Communities of Seaside and Rosemary Beach. Following closely behind is the trade, transportation & utilities sector, accounting for 20.3 percent of employment, while construction stands at 10.0 percent in third place. Education, health care services, and public administration also play significant roles within the top five employment sectors, reflecting the diversified economic landscape of the county (Walton County Local Mitigation Strategy Plan, 2015).

The natural environment in Walton County contributes to its distinctive appeal to visitors and tourists. The county's coastal environment along the Gulf of Mexico showcases picturesque vistas, including white sand beaches, undulating dunes, and coastal dune lakes. These lakes, a rarity worldwide, provide unique ecological habitats. Walton County is also committed to environmental conservation, with designated protected areas comprising state parks, forests, and wildlife management zones. These preserved landscapes offer abundant opportunities for recreational activities, including hiking, fishing, and birdwatching.

The presence of wetlands and waterways further enhances the natural attributes of Walton County. Various rivers and creeks alongside Choctawhatchee Bay permeate the landscape, fostering

diverse ecosystems and serving as crucial habitats for a wide range of wildlife species. This rich natural heritage encourages exploration and nurtures an appreciation for the environment.

DeFuniak Springs serves as the county seat and boasts a diverse economy. Anchored by sectors such as healthcare, education, retail, government services, and a thriving small business community, DeFuniak Springs offers a range of employment opportunities. Surrounded by the natural beauty of forests, lakes, and wetlands, the city enjoys the presence of Lake DeFuniak, a noteworthy natural resource. With a population of approximately 5,100 residents, DeFuniak Springs is a vibrant city featuring a mix of economic activities. The land area of DeFuniak Springs is approximately 12.6 square miles (32.7 square kilometers).

Freeport boasts a diverse demographic profile, and a developing economy. The city is situated along the shores of Choctawhatchee Bay, which provides opportunities for recreational opportunities and supports local ecosystems. Surrounded by lush forests and intersected by waterways, Freeport enjoys a rich environmental setting. In terms of economics, Freeport's economy is in a phase of growth and diversification, with sectors including healthcare, education, retail, and small businesses. The city is also strategically positioned for future economic expansion due to its proximity to major transportation corridors. Demographically, Freeport is a close-knit community with a population of approximately 2,600 residents, comprising a mix of permanent residents, retirees, and individuals seeking a suburban or rural lifestyle. The city reflects a diverse demographic composition, showcasing a variety of cultures, and backgrounds. Freeport occupies a land area of about 13.6 square miles (35.3 square kilometers)

Further along the coast, Miramar Beach stands as a coastal gem known for its tourism and hospitality industry. Luxury resorts, vacation rentals, gourmet restaurants, high-end retail shops, and entertainment venues thrive within this bustling city. Miramar Beach's main attraction lies in its stunning white sand beaches along the Gulf of Mexico, providing endless opportunities for beach activities and water sports. Its boundaries extend into neighboring Okaloosa County, attracting a blend of permanent residents, vacation homeowners, and rental property occupants. Miramar Beach, including its neighboring areas, covers an estimated land area of around 4.7 square miles (12.2 square kilometers).

Continuing along the Gulf Coast, we encounter Santa Rosa Beach. This coastal community is renowned for its vibrant tourism industry, offering a plethora of accommodations ranging from upscale resorts to charming vacation rentals. Its demography reflects a mix of permanent residents, seasonal visitors, and individuals seeking a coastal lifestyle, resulting in a diverse and dynamic community. Santa Rosa Beach spans a larger area compared to other cities in Walton County, with an estimated land area of approximately 31.2 square miles (80.8 square kilometers).

A summary of the existing CRS classifications for the communities in the study area is listed in **Error! Reference source not found.**. No cities in Walton County are listed in the FEMA Community Rating System Eligible Communities.

Table 1: Community Rating System for Walton County. Effective April 1, 2023.

Community #	Community Name	CRS Class Rating	Premium Discount for SFHA	% Discount for Non- SFHA	Status
120317	Walton County	6	20%	10	Cycle

Based on the future land use for Walton County, only 7.07% of the land use in the county is urban and built up, and water/wetlands makes up 29.16% of the land use. The majority of land is upland forest, with 48.3%, as shown in **Error! Reference source not found.**.

Table 2. Land use table for Walton County (2023 Florida Geographic Data Library (FGDL)).

Level 1 Land Use-Land Cover Type	Area (Acres)	Percentage of Total
Agriculture	52958.94669	7.17%
Barren Land	9242.05986	1.25%
Rangeland	40326.66002	5.46%
Transportation, Communication, and Utilities	11815.69287	1.60%
Upland Forest	356796.0541	48.30%
Urban and Built-Up	52194.79061	7.07%
Water	61593.80508	8.34%
Wetlands	153759.9055	20.82%
Total	**738687.9147**	**100.00%**

Walton County has a history of flooding and has implemented various measures for flooding mitigation over the years (see section 2.12 for more details). The County has experienced flooding primarily due to heavy rainfall events and proximity to large water bodies such as the Gulf of Mexico, Choctawhatchee Bay, and numerous rivers and creeks. The topography of the region, with low-lying areas in the coastal areas and wetlands, also contributes to flood vulnerability. The proximity to the ocean (Gulf of Mexico) makes the county vulnerable to sea level rise. Over the years, Walton County has faced multiple flooding incidents, including:

- March 1997: Heavy rainfall led to significant flooding throughout the county, resulting in property damage and road closures.
- April 2009: Intense storms caused widespread flooding, damaging homes and infrastructure and resulting in the declaration of a state of emergency.
- April 2014: Heavy rainfall caused severe flooding, leading to the evacuation of some residents and the closure of roads.

Today, the goal of a stormwater management system in many communities is to keep the community as a place to live and do business while limiting risk from damage due to flooding. The short-term impacts from stormwater include flooding in low-lying areas and standing water in areas with limited soil storage capacity. Less common, but of increasing frequency, is the potential for extensive inundation of some areas, especially low-lying areas, during periods with high groundwater levels and groundwater impacted by sea level rise. As a result, there is a need to

understand the economic impact of flooding events and to create cost-effective stormwater infrastructure and policy solutions to protect property. This means preserving as much property and economic activity as possible without disrupting current activity or expending funds on inappropriate projects with limited long-term or social value.

1.1 Surface Topography

Topography is a key parameter that influences many of the processes involved in flood risk assessment, and thus, up-to-date, high-resolution, high-accuracy elevation data are required. In order to meet the requirements for FEMA Risk Mapping, Assessment, and Planning (RiskMAP), 1-meter (2015 to present) and 1/9 arc-second (~ 3-meter) (2010 -2015) LiDAR DEMs were acquired. The 1 m × 1 m LiDAR tiles were kriged to create a topographic map of the study area (**Error! Reference source not found.**). This accuracy meets the 3DEP Quality Level 2 vertical root mean square error accuracy threshold of ±10 cm for FEMA (Arundel et al., 2015). The LiDAR used for this basin was 2016.

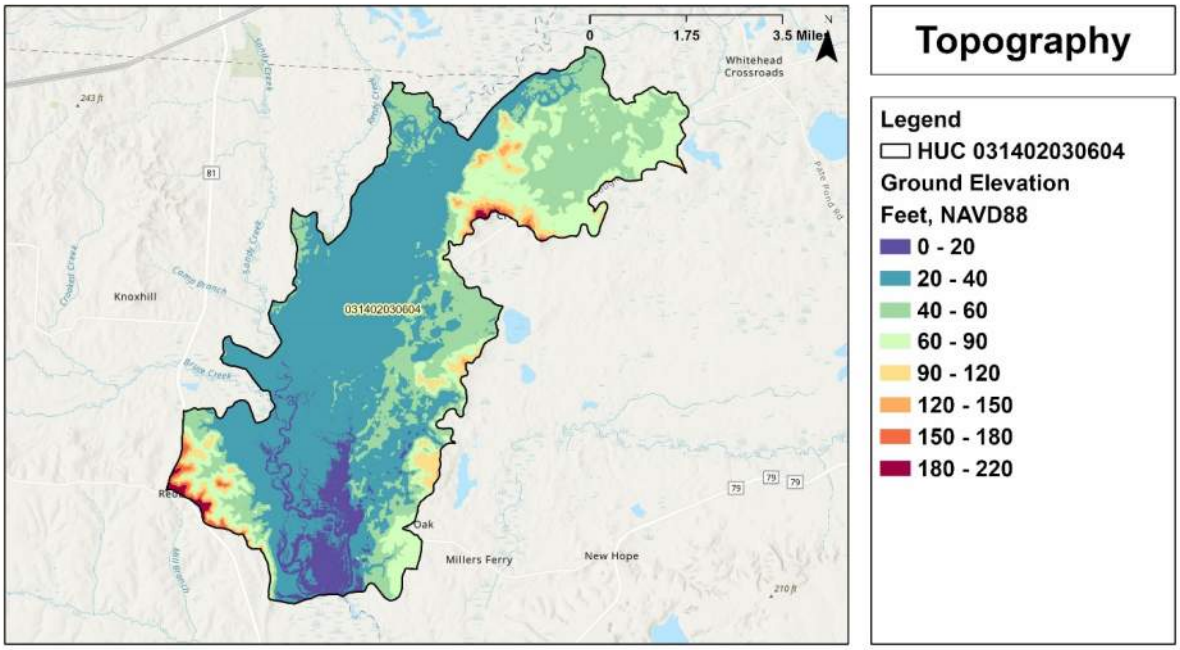

Figure 4. Topographic map of the HUC 031402030604 sub-watershed, processed by FAU

1.1.1 Geomorphological Considerations

Walton County's coastal area is characterized by the presence of barrier islands, extensive sandy beaches, and coastal dune systems. These features are influenced by the dynamic processes of wave action, tidal currents, and wind-driven sediment transport. The shoreline is subject to natural changes, including erosion and accretion, which significantly shape the coastal geomorphology.

Inland Walton County exhibits a mix of wetlands, forests, rolling hills, and rivers. These landforms are influenced by a combination of factors, including underlying geology, fluvial processes, and the region's hydrological regime.

Like many areas in Florida, Walton County is underlain by limestone formations. The specific composition and properties of these limestone formations in Walton County may vary. However, limestone is generally known for its porous nature, which allows for the absorption and storage of water. Underground aquifers within the limestone formations can hold significant volumes of freshwater, contributing to the region's water resources.

For context, the FIRM panel index of HUC 031402030604 sub-watershed is shown in **Error! Reference source not found.**.

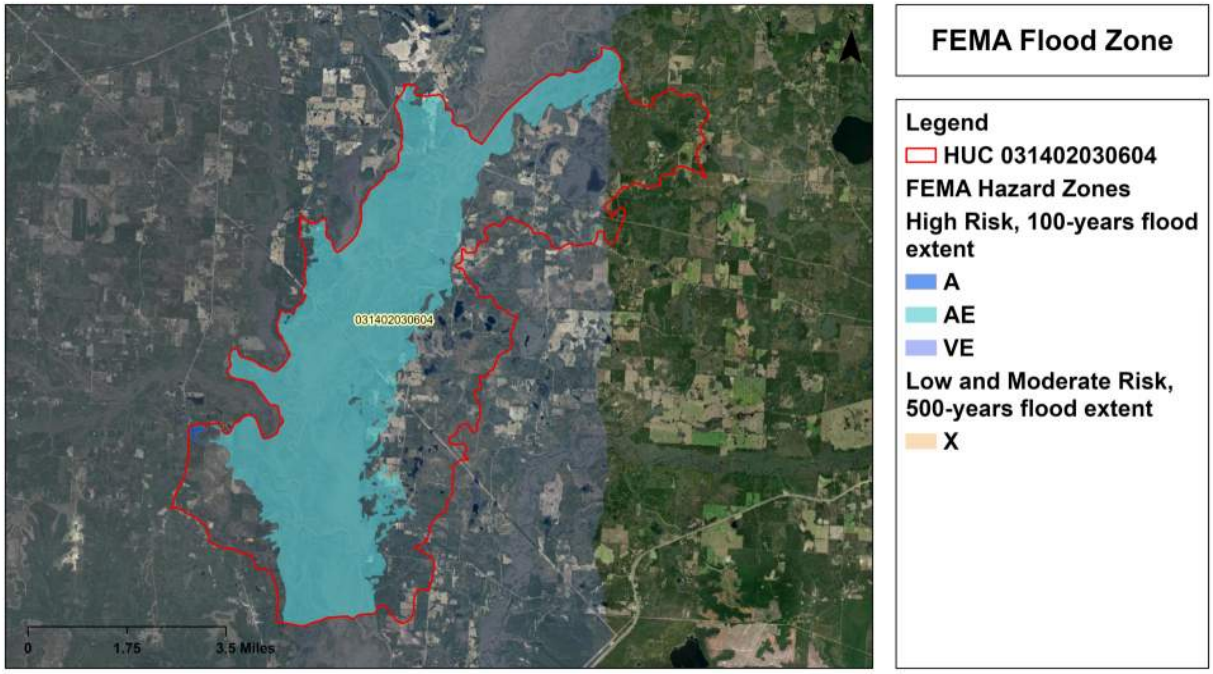

Figure 5. FEMA Flood Zone map (2020) for HUC 031402030604 sub-watershed, processed by FAU.

1.1.2 Waterway Features

In Walton County, Florida, the waterway features are primarily influenced by the presence of rivers, creeks, bayous, and the proximity to the Gulf of Mexico. To the south of Walton County lies the Gulf of Mexico. Sandy beaches, barrier islands, and the open waters of the Gulf itself characterize the coastline along the Gulf. The Gulf of Mexico influences the coastal processes, including wave action, tidal currents, and sediment transport along the shoreline. The combination between sea level rise and King tide would have detrimental consequences for the county costal

area, including the sub-watershed 031402030604 as it will reach the area thought Choctawhatchee Bay.

Walton County is home to several rivers and creeks that meander through its landscape. These waterways provide drainage for the inland areas and contribute to the overall hydrological system. Examples of significant rivers in the county include the Choctawhatchee River and the Shoal River. In addition, Walton County features bayous and estuaries that connect inland water systems to the Gulf of Mexico.

Choctawhatchee Bay serves as a vital estuarine ecosystem, where freshwater from rivers and creeks mixes with the saltwater from the Gulf of Mexico, serving as a vital estuarine ecosystem. This unique brackish water environment supports a rich diversity of flora and fauna, including various fish species, shellfish, migratory birds, and wetland vegetation, contributing to the overall biodiversity of the region. It also plays a significant role in the local economy of Walton County as it supports commercial and recreational fishing industries, providing livelihoods for local fishermen and contributing to the seafood industry, while also offering a range of recreational opportunities for residents and visitors alike, such as boating, kayaking, paddle boarding, and sailing. **Error! Reference source not found.** shows the bathymetry offshore.

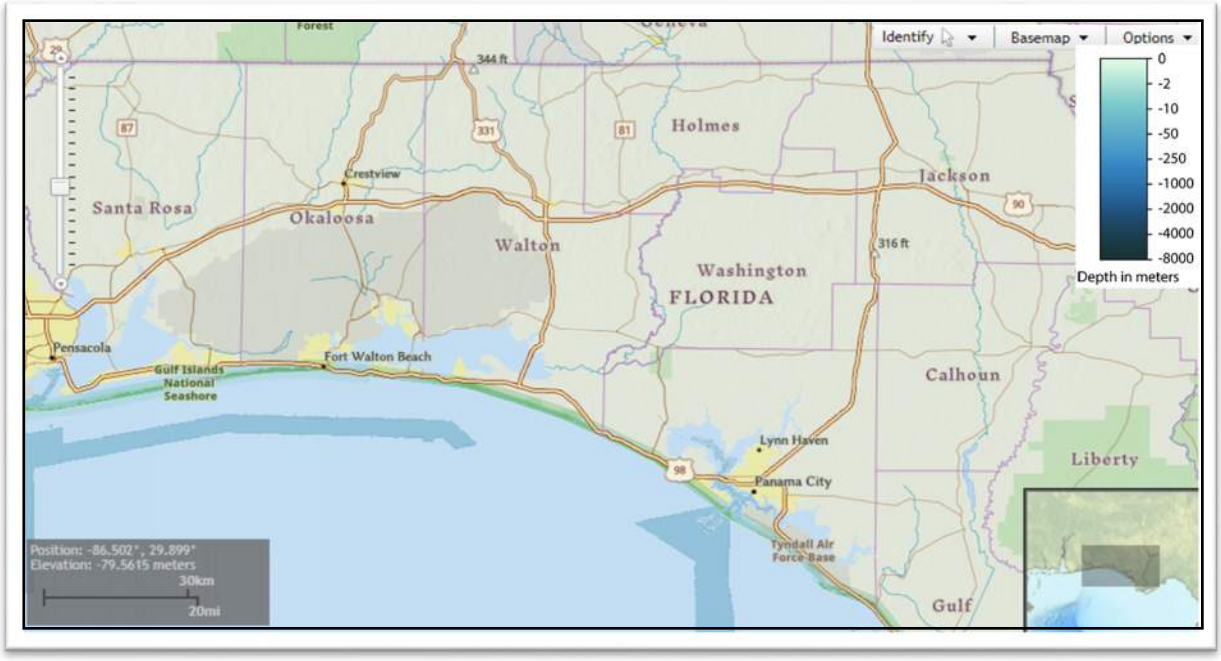

Figure 6. Bathymetry map of the shore of Walton County and surrounding counties of Florida Panhandle.
Source: ncei.noaa.gov/maps/bathymetry/

Numerous tributaries exist throughout both the freshwater and estuarine portions of the watershed and can influence the overall hydrology of the area depending on rainfall and regional hydrological conditions. **Error! Reference source not found.** shows the location of all four surface water stations along with ground water stations (wells) and the drainage network of Walton County.

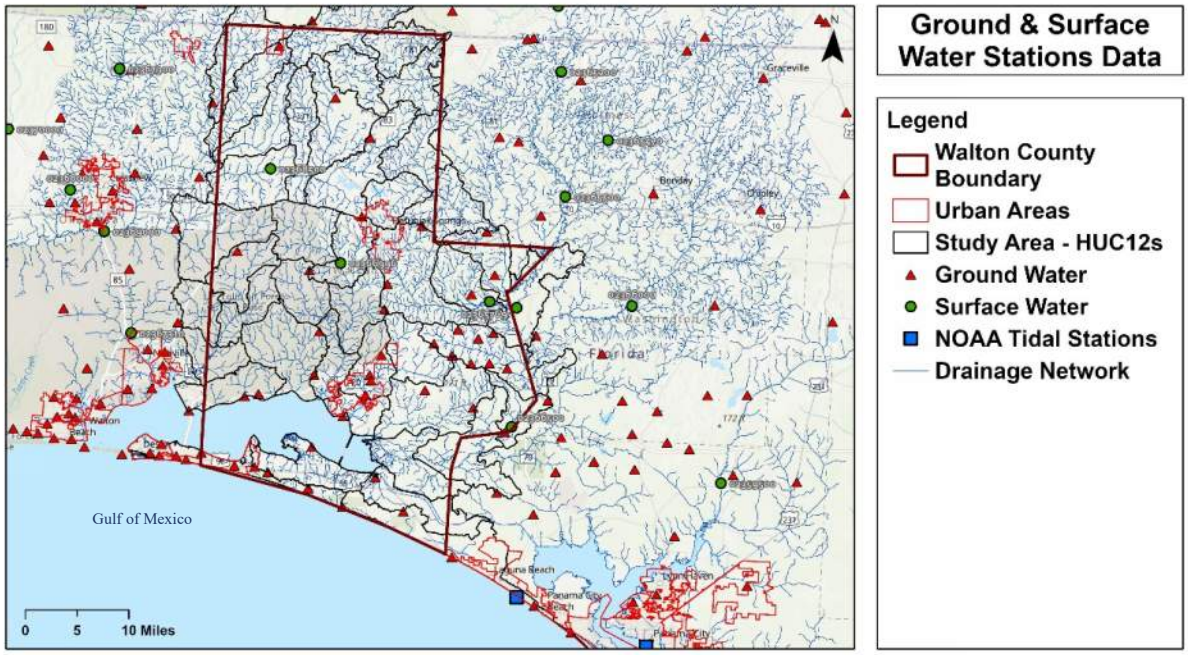

Figure 7. Ground & Surface Water Stations with drainage network for Walton County, processed by FAU.

1.1.3 Hydrologic Boundaries

The geographic area of the subject sub-watershed should be clearly defined to ensure that implementing the WMP will address all the major sources and causes of impairments and threats. Although there is no rigorous definition or delineation of this concept, one way to identify the geographic extent of the watershed master planning effort is to consult the United States Geological Survey (USGS) map of hydrologic units. A hydrologic unit is part of a watershed mapping classification system showing various areas of land that contribute surface water runoff to designated outlet points, such as lakes or stream segments. USGS designates drainage areas as sub-watersheds (including smaller drainages) numbered with 12-digit hydrologic unit codes (HUCs), nested within watersheds (10-digit HUCs). These are combined into larger drainage areas called subbasins (8 digits), basins (6 digits), and subregions (4 digits), which make up the large regional drainage basins (2 digits).

Region>>Subregion>>Basin>>Sub-basin>>Watershed>>Sub-watershed

The major water bodies in the HUC 031402030604 sub-watershed include:

- Choctawhatchee River
- Mill Creek
- Hughes Ditch
- Carlisle Lake
- Yates Mill Creek

Given that stream flow data are critical for estimating flooding, **Error! Reference source not found.** shows the historical streamflow during June 2022 to July 2023 for USGS 02365769. However, as there are only four surface water station within Walton County, it was necessary to use the nearest station to the sub-watershed 031402030604, which is USGS 02365769 Bruce Creek at SH 81 NR Redbay, FL.

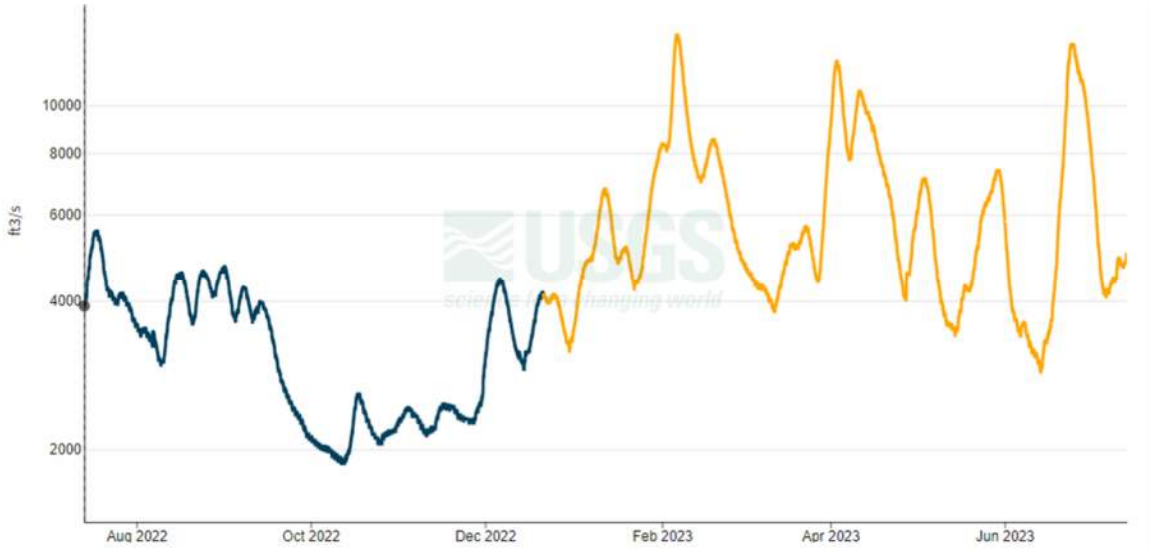

Figure 8. Average streamflow for Bruce Creek at SH 81 NR Redbay, FL (USGS 02365769 Surface-Water, June 2022 to July 2023).
Source: USGS Water Data Services (https://waterdata.usgs.gov/monitoring-location/02365769/#parameterCode=00065&period=P7D).

1.2 Groundwater

In this region of Florida, there is a direct interaction between groundwater and surface water. In addition to low land elevations and topographic relief, the groundwater and surface water are controlled by the canals, rivers, and tides. Since there is a limited number of groundwater monitoring stations, the strong relationship between groundwater and surface water was leveraged to develop a 99th- percentile surface of the water table elevation for mapping purposes. To establish a common date for modeling, the recorded groundwater table elevations were sorted in ascending order to determine the 98th - 100th percentile date of occurrence in Excel®, following the procedure detailed in Romah (2011). This procedure was automated for this effort using a python code to process the groundwater data more efficiently. Outliers and anomalous groundwater levels in the

database are initially identified (e.g. catastrophic storm events) and replaced by region-specific mean values based on observations available from the nearest well. Missing date-specific data are estimated using simple temporal interpolation based on observations available in time. If a station (or monitoring well) data contains large amounts of missing data, it is not used in the generation of the groundwater surface.

In Walton County, the average annual rainfall is abundant, reaching 65 inches at DeFuniak Springs. This rainfall predominantly infiltrates the sand-and-gravel aquifer and eventually seeps into streams or the underlying artesian Floridan aquifer. The county's two major aquifers are the sand-and-gravel aquifer and the Floridan aquifer. While the sand-and-gravel aquifer provides water for rural domestic use and plays a crucial role in water storage and streamflow maintenance, it also serves as a recharge source for the Floridan aquifer. Water from the sand-and-gravel aquifer contains varying levels of dissolved solids, pH, and iron content. The Floridan aquifer, being the primary water supply source, underlies the entire county and yields around 500 to 1,000 gallons per minute from wells, except along the Gulf Coast where the permeability is lower. Recharged by leakage from the sand-and-gravel aquifer, the Floridan aquifer's movement is predominantly southward away from the potentiometric high in northwestern Walton County. It discharges through springs, seeps along the Choctawhatchee River, and by wells. In southern Alabama, the Floridan aquifer is directly recharged by rainfall when it is exposed or close to the land surface. (Bureau of Ecology, 1974).

Once a common time period is determined across the majority of shallow groundwater wells, canal data can be gathered for that common date (and two days prior, in the event the canals were deliberately lowered). Data was obtained from the NWFWMD and processed by FAU at cwr3.fau.edu. Between stations, an ArcGIS tool permits a line to be drawn to replicate the rivers and streams to establish points for a gradient between stations. The same is true for the ocean, but it is a constant head boundary. The topography and points where streams join form boundary conditions for the screening tool on the edges of the basin and affect localized groundwater. The tide issue is resolved by using the common date for high tide.

Error! Reference source not found. shows the drainage network of HUC 031402030604 and points out the location of the ground water stations in the surroundings. A groundwater-surface layer for the HUC 031402030604 sub-watershed was created using several datasets including water level data from USGS and NWFWMD and groundwater elevation contour maps. The datasets were used to generate a raster surface of the groundwater elevation (**Error! Reference source not found.**).

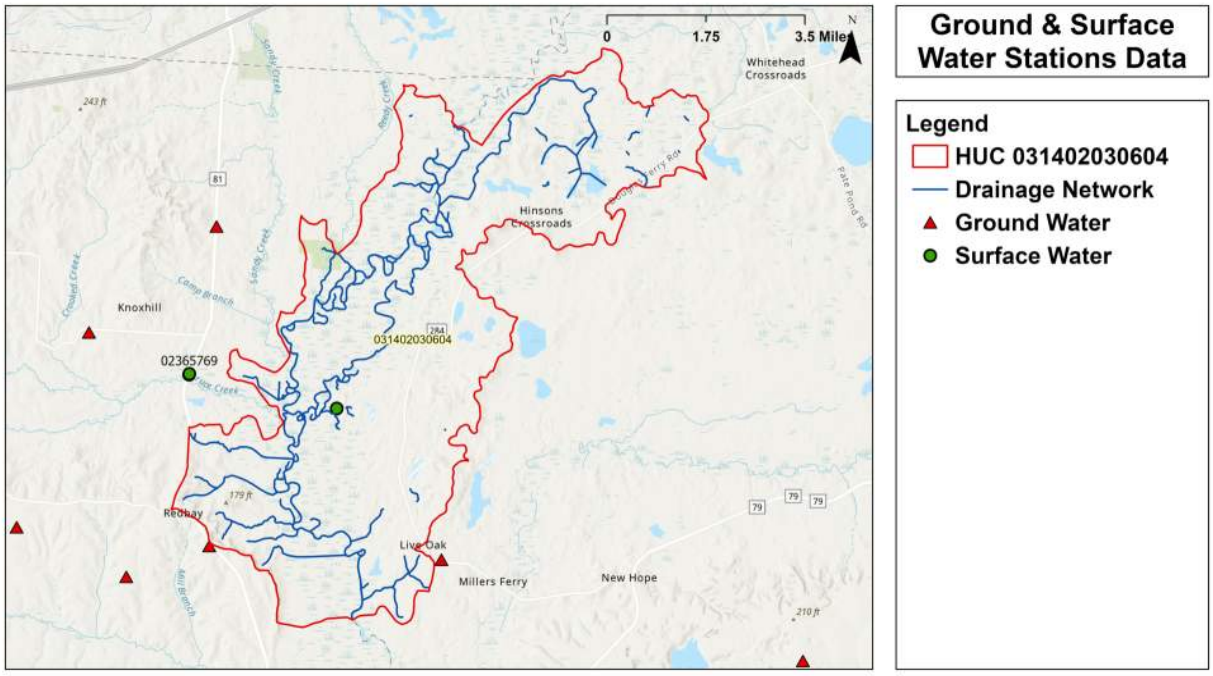

Figure 9. Ground and Surface Water Stations in the HUC 031402030604 sub-watershed, processed by FAU.

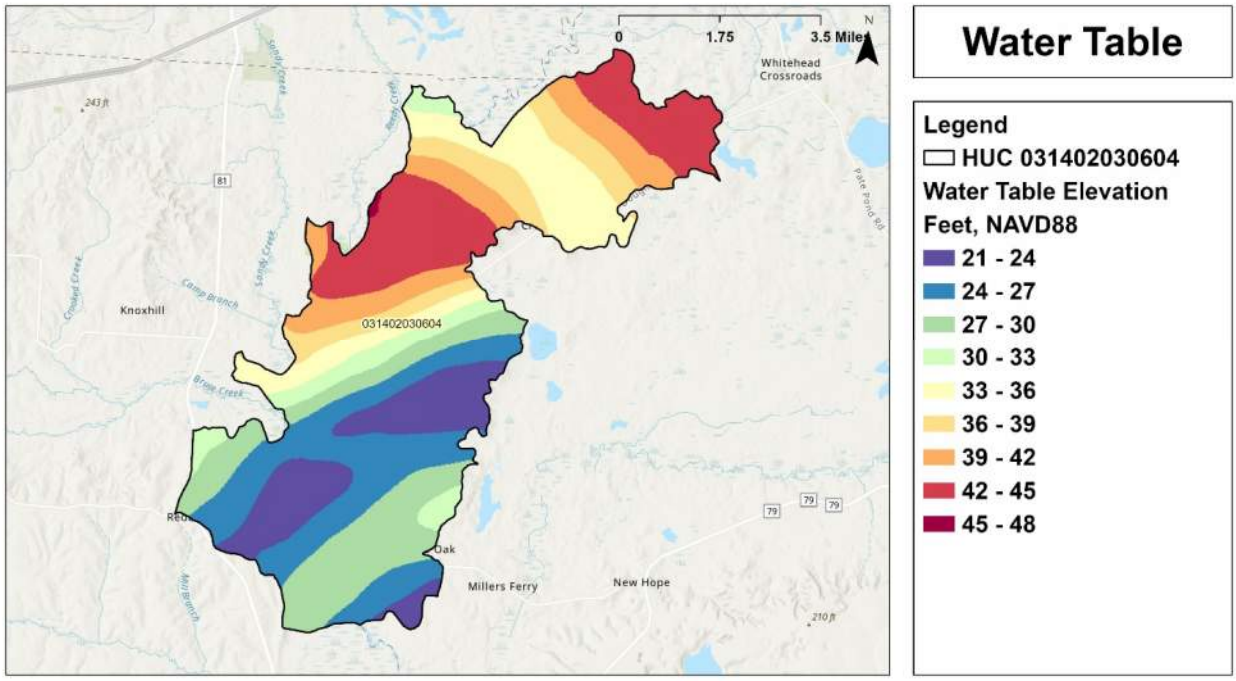

Figure 10. Elevation of the top of the surface groundwater layer for the HUC 031402030604 sub-watershed, created by multiple linear regression analysis – elevation NAVD88, processed by FAU.

1.3 Surface Water/Tides

Historically, surface water and tides have been an important factor in determining how much freshwater is delivered, how fast this water enters wetlands and estuaries, and the quality of that water. Evapotranspiration and rainfall do not coincide in the study area, which makes water supply planning difficult. **Error! Reference source not found.** shows the observed rainfall over Walton County for every month between 1900 and 2023 - each rectangle is a month and each column is a year. The 12-month total precipitation decreased 7.5 inches from May 1900 to April 2023. From May 1900 to April 2023, the average 12-month total precipitation was 60.5 inches, for the entire county.

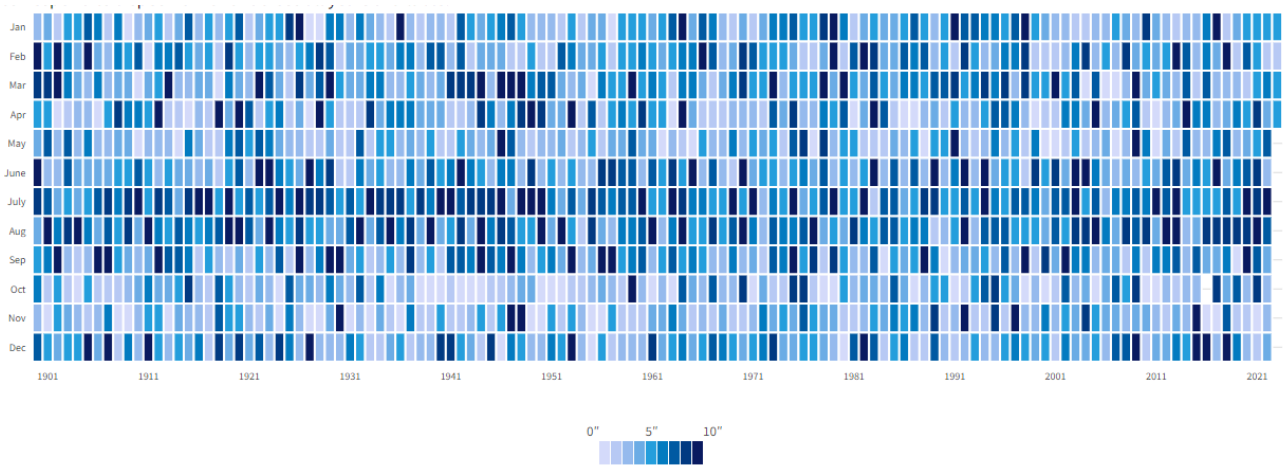

Figure 11. Monthly precipitation in Walton County, FL.
Source: National Centers for Environmental Information
(https://usafacts.org/issues/climate/state/florida/county/walton-county/#precipitation/).

While the topography (Section 1.1) and native soil (Section 1.4) create an environment that is highly permeable and capable of infiltrating significant percolation into the soil, changes in land use and land cover have resulted in water falling on impervious areas, where the water collects in pools or runs off rapidly, in direct contrast to the natural condition. This runoff flowing over impermeable regions can lead to larger scale flooding.

Tidal data can be gathered from NOAA tidal gages and other gages monitored by local governments. The location of tide gages is important to ensure they accurately depict tides, as opposed to inland waters. To set a boundary for the coastal areas, the high tide on the common date from 12/03/2018 to 12/10/2018 was selected. **Error! Reference source not found.** shows the two closest tide stations to Walton County. Since there is no NOAA tide station in Walton County, the Panama City Beach station (8729210) was used.

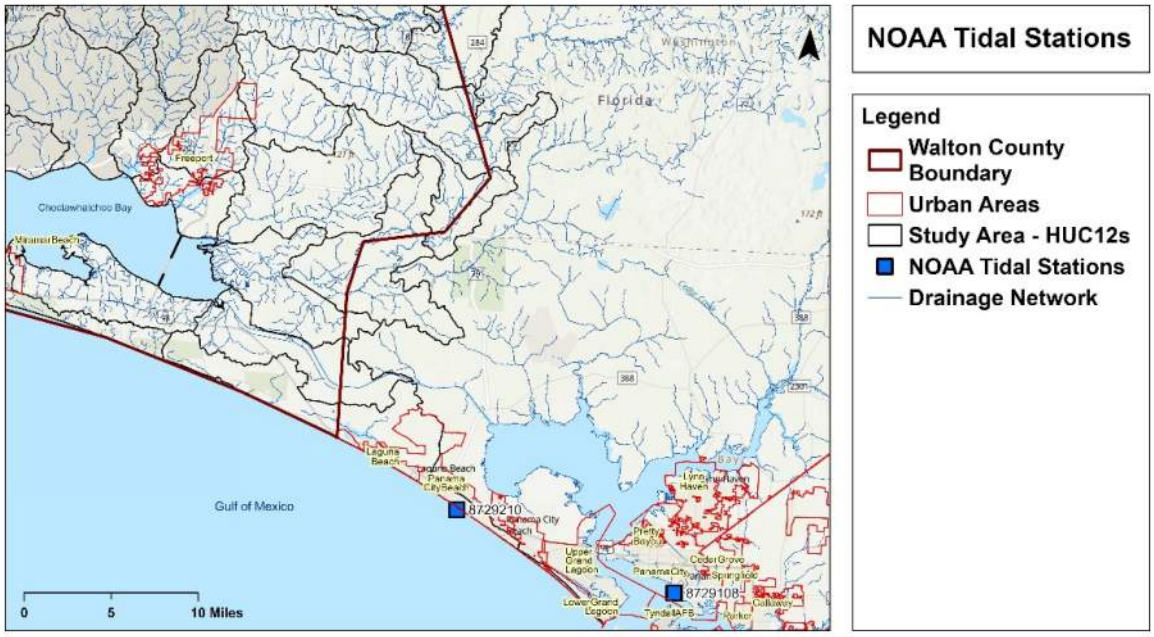

Figure 12. Locations of Florida tidal stations maintained by NOAA near to Walton County, processed by FAU.

1.4 Soils

Soil can store water if there is adequate distance between the topographic surface and the groundwater, and the soil types are capable of absorbing the water. Soil storage capacity is the volume of soil pores in the unsaturated zone that is available to store infiltrated stormwater (Gregory et al., 1998). Throughout Florida, it is common to have large volume storm events that fill the voids in the unsaturated zone as shown in **Error! Reference source not found.**.

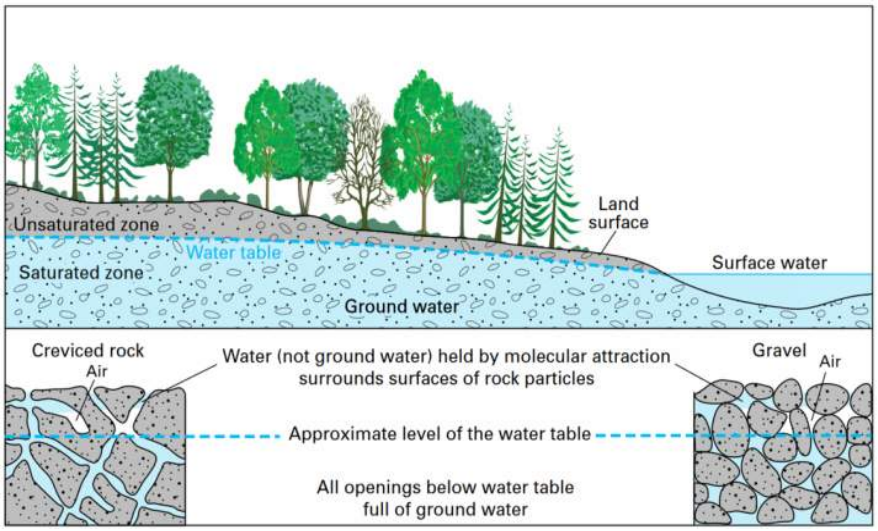

Figure 13. Zones where underground water exists.
Source: USGS, 2020.

The unsaturated zone is the portion of the subsurface above the water table that contains soil/rock and air and water in its pores as shown in **Error! Reference source not found.**.. This zone affects the rate at which the aquifer is recharged by controlling water movement from the surface of the land downward towards the aquifer. During rain events, the soil voids fill up quickly resulting in the water table rising to the surface, and the surplus rainfall becomes runoff.

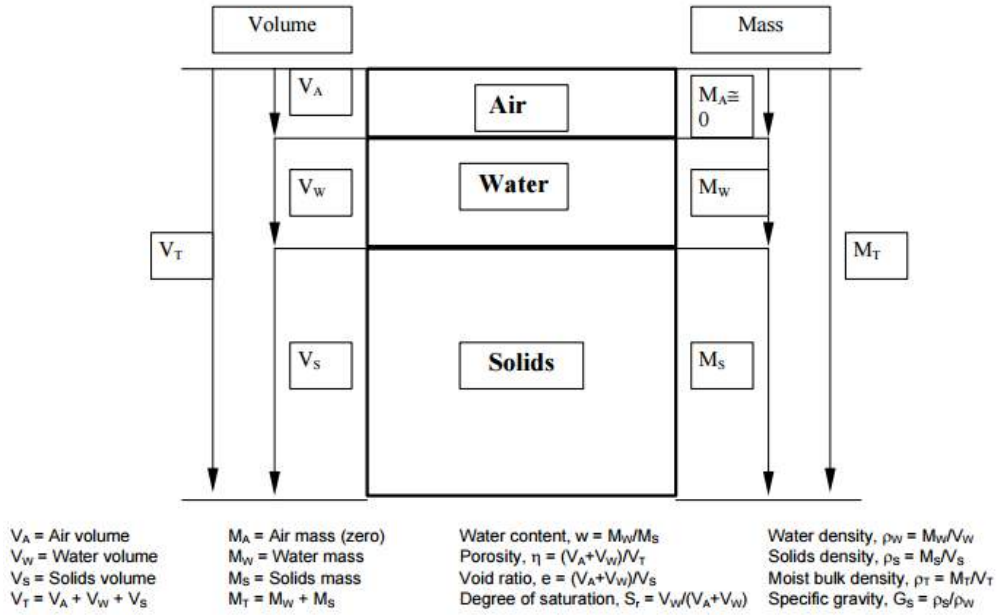

Figure 14. Saturated zone soil phase diagram and definitions.
Source: Gregory et al., 1998.

Soil data is available from the United States Department of Agriculture (USDA) or other agencies in the form of maps that can be incorporated as a GIS layer. The Gridded SSURGO (gSSURGO) dataset from USDA is chosen. This dataset is similar to the standard product from USDA Natural Resources Conservation Service (NRCS) Soil Survey Geographic (SSURGO) database, but is in the Environmental Systems Research Institute, Inc. (ESRI®) file geodatabase format. A file geodatabase allows for statewide or even Conterminous United States (CONUS) tiling of data. The gSSURGO dataset contains all of the original soil attribute tables in SSURGO. All spatial data are stored within the geodatabase instead of externally as separate shape files. Both SSURGO and gSSURGO are considered products of the National Cooperative Soil Survey (NCSS). **Error! Reference source not found.** shows the unsaturated zone found by the difference between the groundwater elevation layer and surface topography.

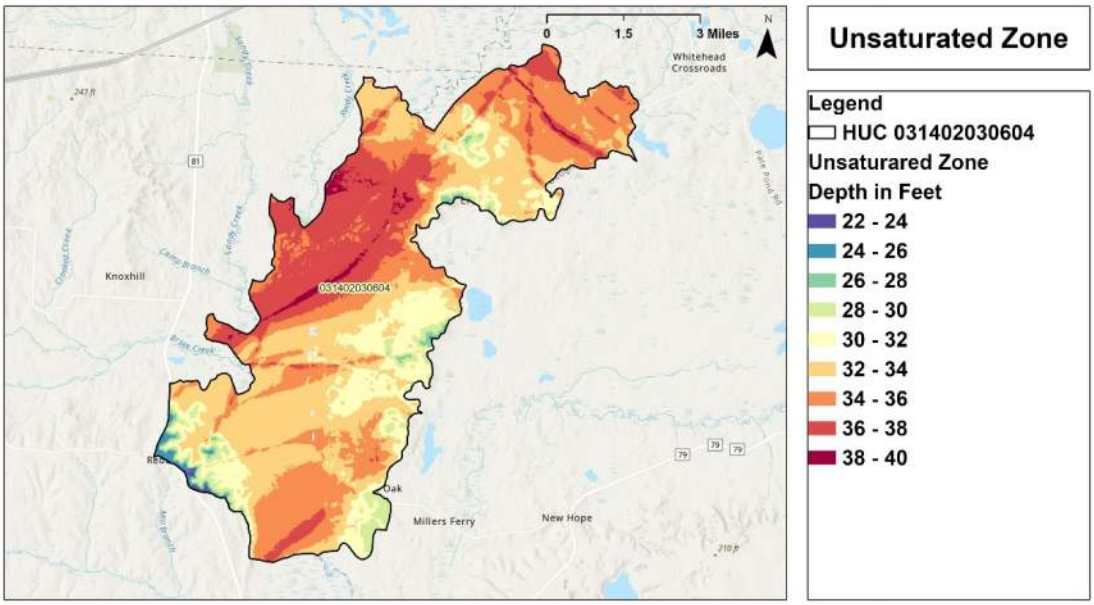

Figure 15. Unsaturated zone map for HUC 031402030604, processed by FAU.

The available water storage from USDA derived for the soil layer (0-150 cm or 0-5 ft) statewide is shown in Figure 16, which covers most of Florida with a spatial resolution of 10 m. The unit is in cm. As a result of applying this layer to the study area (Figure 17), the estimated soil storage capacity can be illustrated. A significant portion of the basin demonstrates a moderately favorable soil storage capacity, falling within the range of 28 to 38 feet of remaining capacity.

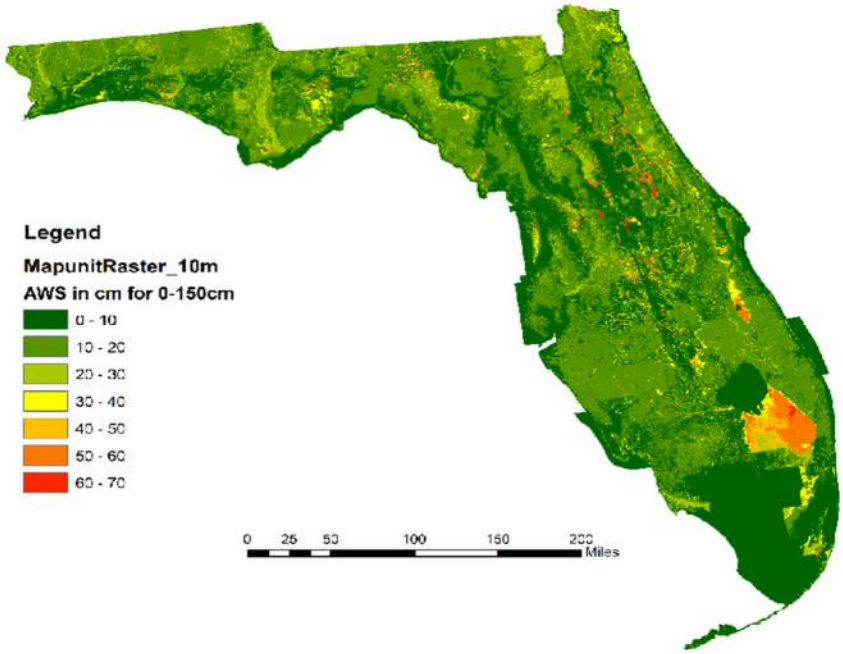

Figure 16. Available water storage derived from the gSSURGO soil database for all of Florida, as processed by FAU.

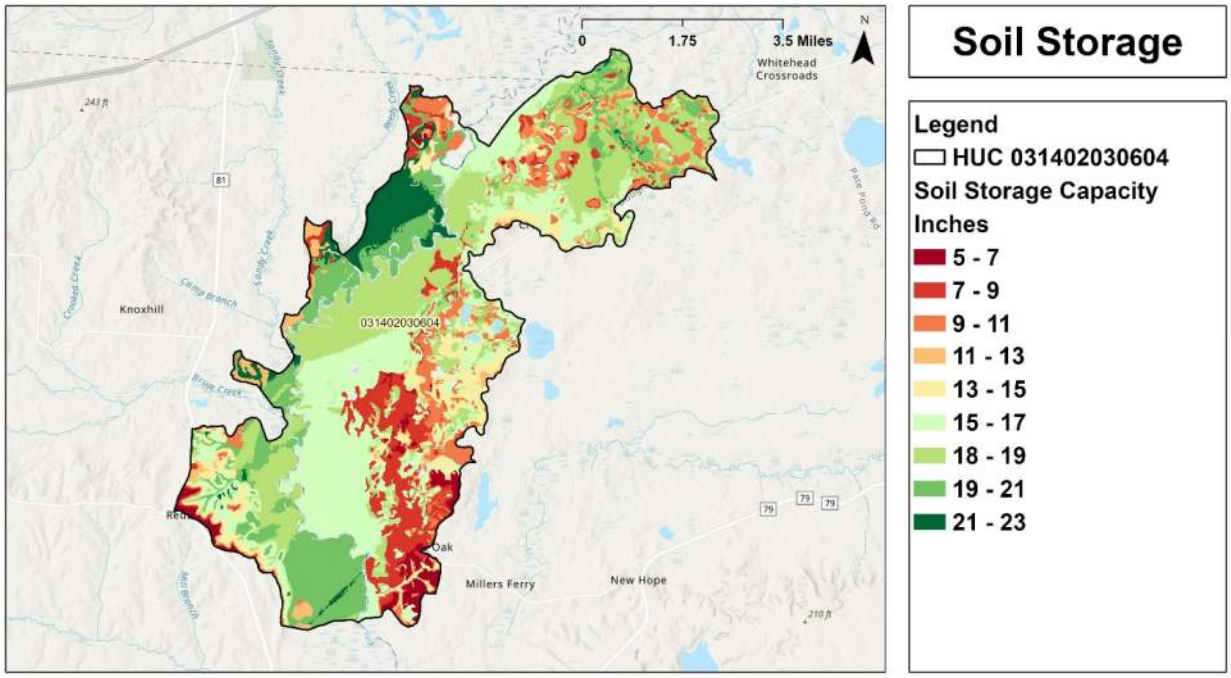

Figure 17. Water storage capacity of soil for the HUC 031402030604, processed by FAU.

Lastly, **Error! Reference source not found.** shows the water holding capacity for the basin, which refers to the capacity of a particular soil texture to retain water against the force of gravity.

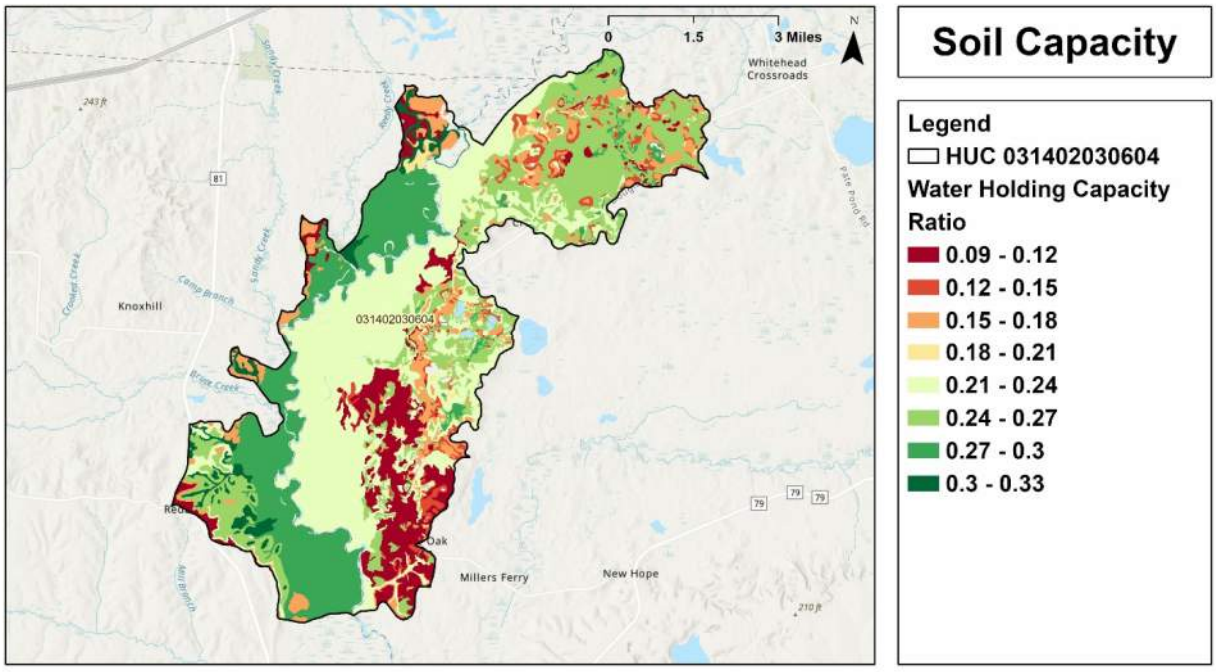

Figure 18. Water Holding Capacity (ratio) for the HUC 031402030604, processed by FAU.

1.5 Land Cover

The USGS produces the NLCD of nationwide data on land cover at a 30-m resolution with a 16-class legend based on a modified Anderson Level II classification system. NLCD is coordinated through the 10-member Multi-Resolution Land Characteristics Consortium (MRLC) to provide digital land cover information nationwide. For the conterminous United States, NLCD 2016 contains 28 different land cover products characterizing land cover and land cover change across 7 epochs from 2001-2016, urban imperviousness and urban imperviousness change across 4 epochs from 2001-2016, tree canopy and tree canopy change across 2 epochs from 2011-2016 and western U.S. shrub and grassland areas for 2016 (**Error! Reference source not found.**).

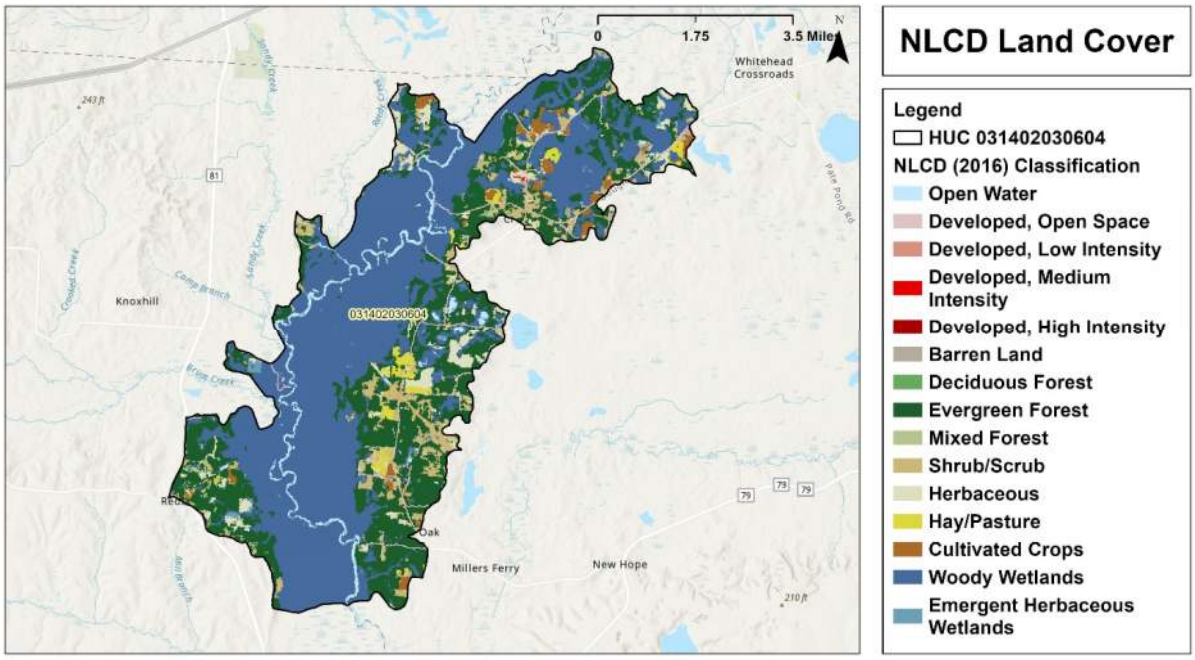

Figure 19. Land use in the HUC 031402030604 (from the NLCD 2016 database), processed by FAU.

The dataset is derived from the Florida Land Use Cover Classification System (FLUCCS), which is digitized by photo-interpretation on county-based aerial photography with varying resolution in the range of 4 in - 2 ft pixel. The NLCD2016 has a 30-meter resolution derived from Landsat imagery. Hence, the NLCD maps appear much coarser and pixelated compared to the 2023 Florida Geographic Data Library (FGDL) (https://fgdl.org/fgdlmap/) maps. A view of the latter is provided in **Error! Reference source not found.**. The future land use maps need to be used for the final land cover, as adjusted for future stormwater improvements set by regulatory standards.

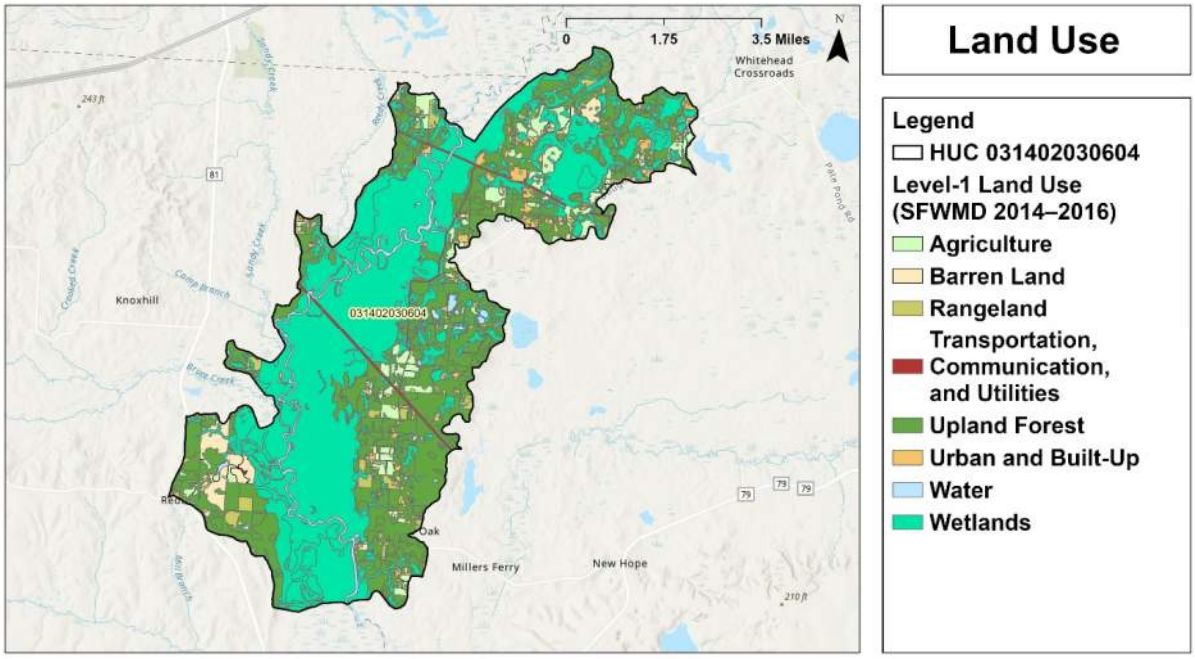

Figure 20. Land use in the HUC 031402030604 (from the 2023 Florida Geographic Data Library (FGDL), processed by FAU.

In the HUC 031402030604 sub-watershed, the predominant land cover is wetlands, accounting for 41.88% of the area. Upland forest comes in second at 30.77%, followed by water at 9.43%, and Transportation, Communication, and Utilities at 9.12%. Developed land constitutes a minor portion, with only 1.88% categorized as urban and built-up, as indicated in Table 3 below.

Table 3. Land use for HUC 031402030604 sub-watershed (2023 Florida Geographic Data Library (FGDL).

Level 1 Land Use Land Cover Type	Area (Acres)	Percentage of Total
Agriculture	1232.50	3.71%
Barren Land	476.09	1.43%
Rangeland	584.87	1.76%
Transportation, Communication, and Utilities	3027.36	9.12%
Upland Forest	10210.45	30.77%
Urban and Built-Up	623.67	1.88%
Water	3127.96	9.43%
Wetlands	13895.01	41.88%
Grand Total:	**33177.90**	**100.00%**

Table 4. Roughness and CN Values for Each Land Use Code.

DOR Code	Use	Impervious %	Roughness
0	Vacant	0	0.4
1	Single Family	29	0.25
2	Mobile homes	21	0.05
4	Condos	60	0.05
7	Vacant –to be developed	0	0.4
8	Multifamily	60	0.05
TH 101	Townhomes	91	0.025
94	Road Right-of-Ways	50	0.08
	Open water	100	n/a
All others	Commercial, etc.	50	0.07

1.6 Precipitation

Rainfall used in the screening tool is based on the SFWMD 3-day 25-year storm, but can be modified for any rainfall event using the accumulated rainfall table obtained from NOAA Atlas 14 Point Precipitation Frequency Estimates (https://hdsc.nws.noaa.gov/hdsc/pfds/pfds_map_cont.html). **Error! Reference source not found.** shows the 3-day 25-year rainfall map based on the NOAA Atlas 14 dataset for the whole state. **Error! Reference source not found.** to **Error! Reference source not found.** rainfall 1-day 100-year, 1-day 10-year, and 1-day 5-year storm event scenarios, in inches.

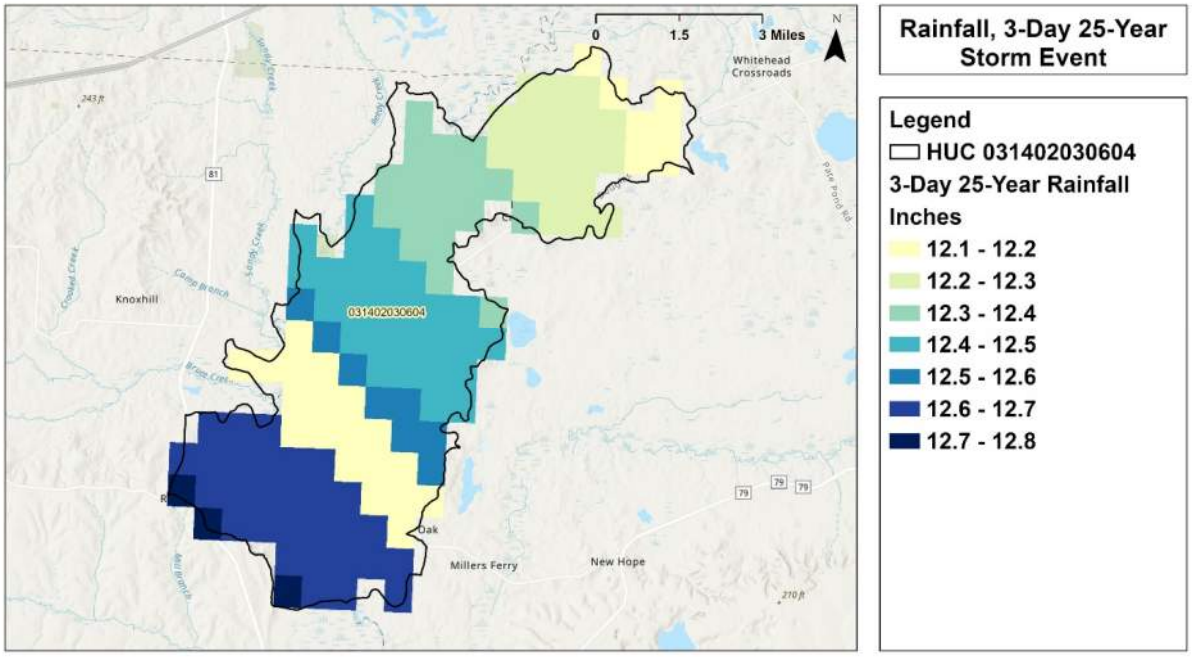

Figure 21. Rainfall distribution map across HUC 031402030604 sub-watershed, for 3-day 25-year storm event, processed by FAU.

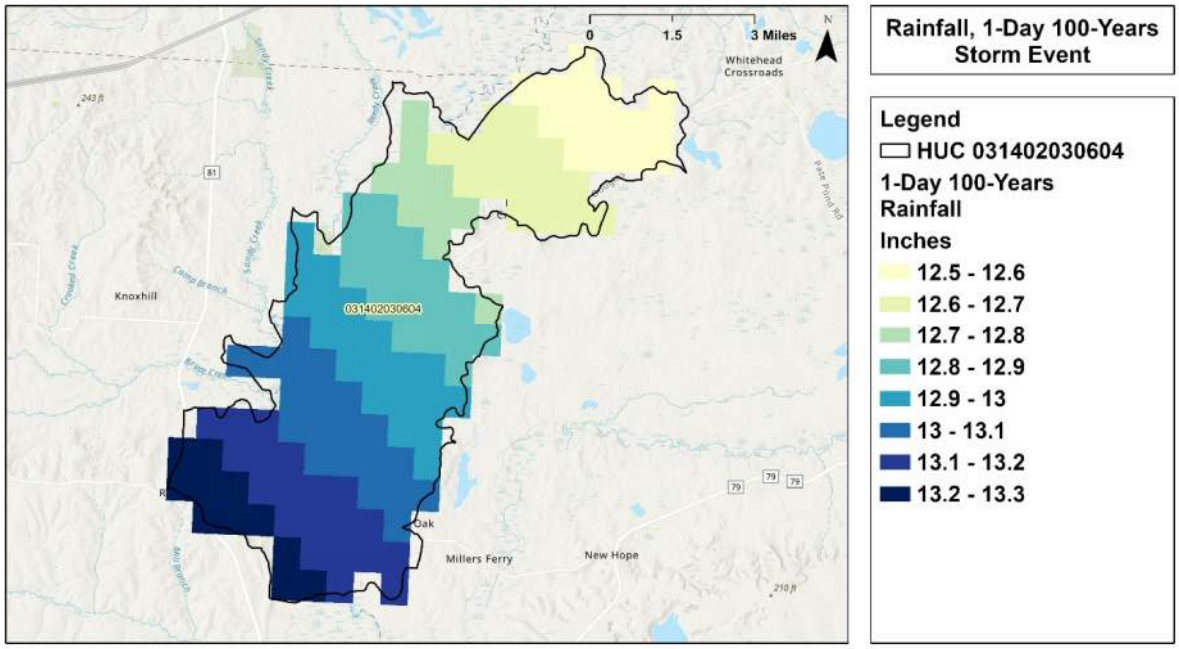

Figure 22. Rainfall distribution map across HUC 031402030604 sub-watershed, for 1-day 100-year storm event, processed by FAU.

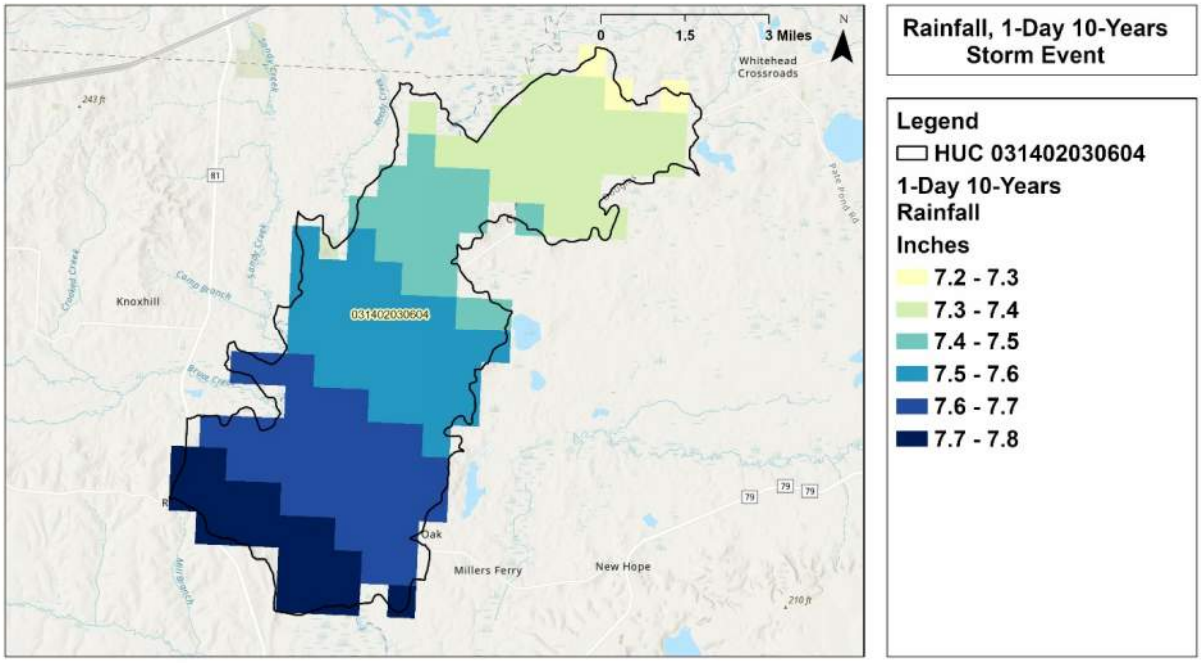

Figure 23. Rainfall distribution map across HUC 031402030604 sub-watershed, for 1-day 10-year storm event, processed by FAU.

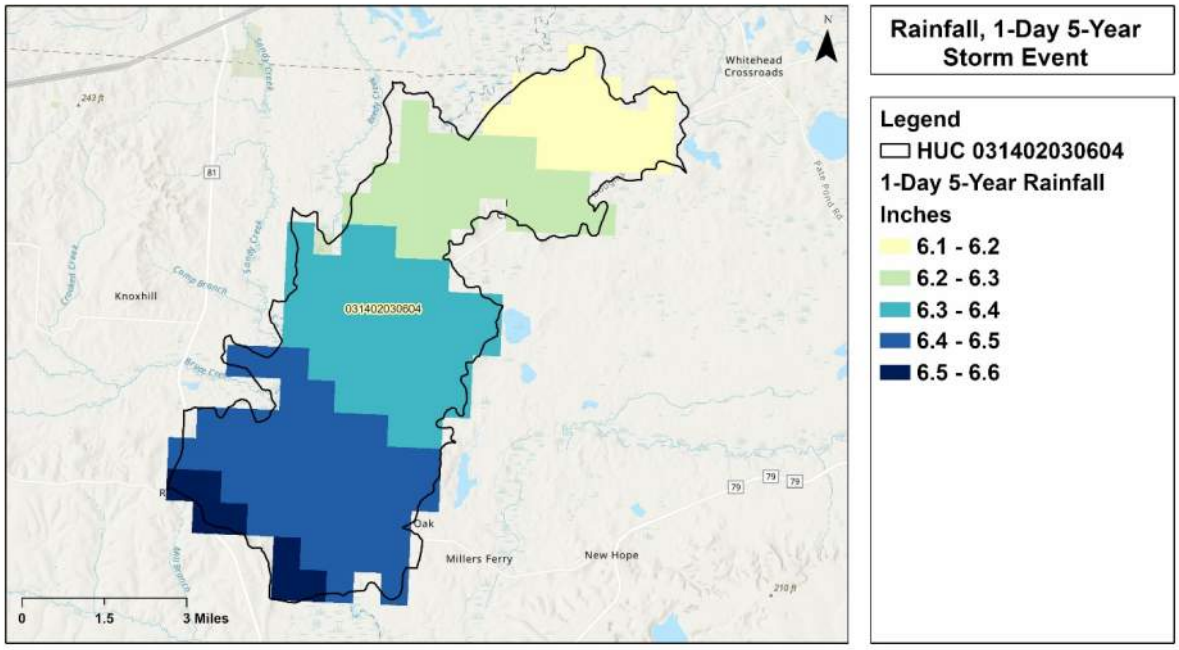

Figure 24. Rainfall distribution map across HUC 031402030604 sub-watershed, for 1-day 5-year storm event, processed by FAU.

1.7 Open Space

Open space is defined as areas that are exempted from development. Generally, this means one or more of the following qualifiers exist:

1. Land that is valuable for recreation, forestry, fishing, or conservation of wildlife or natural resources
2. Land that is a prime natural feature of the state's landscape, such as a shoreline or ridgeline
3. Land that is habitat for native plant or animal species listed as threatened, endangered, or of special concern
4. Land that is a relatively undisturbed example of an uncommon native ecological community
5. Land that is important for enhancing and conserving the water quality of lakes, rivers, and coastal water
6. Land that is valuable for preserving local agricultural heritage
7. Proximity to urban areas or areas with open space deficiencies and underserved populations
8. Vulnerability of land to development
9. Stewardship needs and management constraints
10. Preservation of forest land and water bodies that naturally absorb significant amounts of carbon dioxide

Permanent protection of sensitive areas can provide critical water quality protection and can be achieved through partnerships with landowners, municipalities, land trusts and state agencies. There is limited land in the study area that has been protected via acquisition by federal, state or local agencies, has conservation easements or is designated as wetlands or areas of critical concern. Agricultural land and other land cover will come from the land cover map (in Section 2.5). Added to this will be the water bodies discussed in Section 2.9, which serve a related condition to open space.

1.8 Impervious Areas

Impervious areas do not permit the infiltration of rainfall to groundwater, and because the water cannot infiltrate, it runs off faster. Faster runoff means that flows to water bodies and storm sewers occur faster and with higher peaks. The result is a disruption of the natural and potentially the planned hydrology. Impervious areas include pavement, buildings, and other areas that reduce runoff capacity. In other words, developed areas have much higher imperviousness than open spaces that are natural or agricultural.

The NLCD provides nationwide data on land cover and land cover change at a 30-m resolution with a 16-class legend based on a modified Anderson Level II classification system. Systematically aligned over time, the database offers the ability to understand both current and historical land

cover and land cover change to enable assessment of trends. Using the NLCD 2016 dataset, a layer was created by using only three categories out of the 13 to identify impervious areas such as primary roads in urban areas, secondary roads in urban areas, and tertiary roads in urban areas. The new layer was then converted to match the 3-meter spatial resolution from the DEM and the standard State Plane Coordinate system. **Error! Reference source not found.** shows the impervious areas derived from the NLCD 2016 as updated by the future land use map.

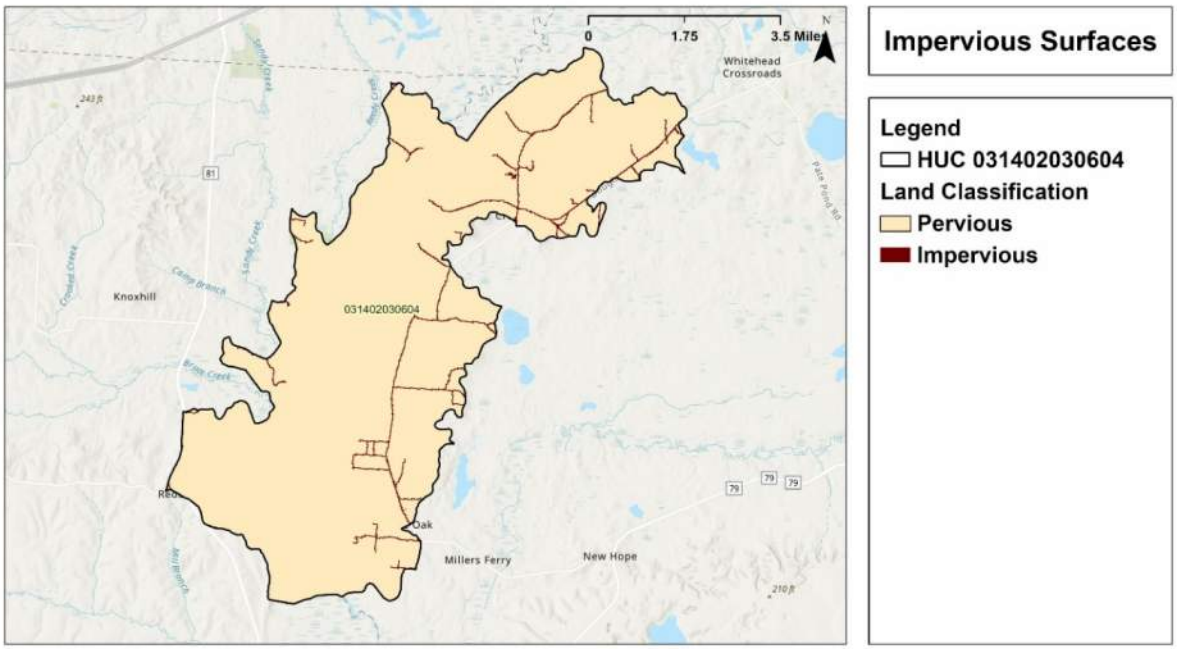

Figure 25. Impervious area map for the HUC 031402030604 sub-watershed, processed by FAU.

1.9 Water bodies

Water bodies were defined in the statewide land use land cover dataset to set soil water holding capacity to zero in model simulations (**Error! Reference source not found.**Note that tiny water bodies may be missing from the maps. Soils were discussed previously in Section 1.4.

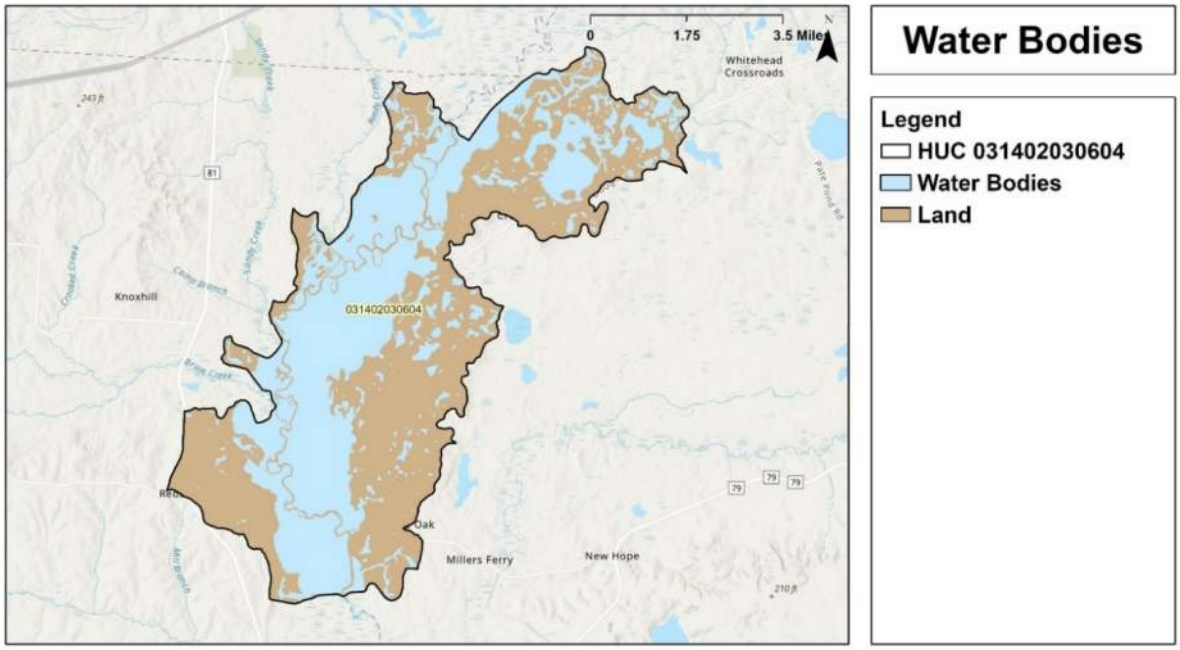

Figure 26. Water bodies map for the HUC 031402030604 sub-watershed, processed by FAU.

1.10. Natural Resources

Understanding the study area's natural resources is critical to identifying potential sources of water quality degradation and areas to designate for conservation, protection, and restoration. One possible goal of watershed master planning is to protect terrestrial wildlife, aquatic habitat, and buffer zones. USGS maintains important sources of information on physical and geographical features as well as soil and mineral resources, surface and ground water resources, topographic maps, and water quality monitoring data. The USDA's Natural Resources Inventory (NRI) (www.nrcs.usda.gov/technical/NRI) is a survey of information on natural resources on non-federal land in the United States that captures data on land cover and land use, soil erosion, prime farmland soils, wetlands, habitat diversity, erosion, conservation practices, and related items. Since 2001, the NRI has been updated continually with annual releases of NRI data from all 50 states. The information provided can be used for addressing agricultural and environmental issues down to the county or cataloging unit level. Therefore, this data can be used to determine erosion and site-specific soil characteristics for certain land uses such as croplands, pasturelands, forestlands, etc., but the data is typically provided as inventories, not GIS layers.

1.11 Demographics

Demographics data is important for determining several key indicators for watershed master planning such as the ability to pay for improvements, social justice issues, land acquisition costs, property/land use, and communication strategies. The US Census has databases at the census tract

level. Based on the census data for the study area, **Error! Reference source not found.** outlines population and racial composition demographics.

Table 5. Demographics and Housing Characteristics of Cities and Towns in Walton County.

Demographic Parameter	**Miramar Beach**	**Freeport**	**DeFuniak Springs, City**	**Paxton**	**Rosemary Beach**	**Santa Rosa Beach***	**Walton County**

** Census Designated Place

1.12 Stormwater Infrastructure Inventory

Local community stormwater systems consist of drainage ditches, storm sewers, retention ponds and other facilities constructed to store runoff or carry it to a receiving stream, lake, ocean, or other waterbody. Other man-made features include yards and swales that collect runoff and direct it to the sewers and ditches. When most of these systems were built, they were typically designed to handle the amount of water expected during a 10-year storm. Larger storms overload them, and the resulting backed-up sewers and overloaded ditches produce shallow flooding. Another urban drainage problem occurs in the areas protected by levees. Being in floodplains, they are flat and do not drain naturally, especially when a levee blocks the flow to the river. To drain these areas, channels have been built and pumps installed to mechanically move the water past the levee. Often, these man-made systems do not have the capacity to handle heavy rains or intense storms.

Another challenge with stormwater infrastructure is related to recordkeeping. It is not uncommon for stormwater data to be incomplete in most jurisdictions and completely lacking in others. Quality of data differs from jurisdiction to jurisdiction; some are in GIS formats, while others are paper maps or as-builts that represent the infrastructure at a macroscale level. The condition of the assets may be lacking, and the maintenance history may not be available either. Stormwater assets may have been installed with no records, especially in rural areas, farm fields, and private property.

Walton County passed Ordinance No. 2008-06 that prohibits unauthorized discharges into storm drains or ditch systems. In addition, the Public Works Division is currently running a continuous public awareness campaign aimed at encouraging the adoption of best management practices (BMPs) for managing stormwater runoff. This initiative targets both the business community and the residents of Walton County.

To address the issue of flooding, Walton County has implemented several measures along the years, such as:

- Drainage Systems: The county has invested in the development and maintenance of drainage systems, including ditches, canals, and retention ponds, to manage stormwater runoff and reduce flood risk.
- Floodplain Management: Walton County has adopted floodplain management regulations and participates in the National Flood Insurance Program (NFIP) to encourage responsible development in flood-prone areas.
- Elevation Standards: New construction projects within flood zones are required to adhere to specific elevation standards to minimize potential flood damage.

- Emergency Response: The county has established emergency response plans to assist residents during flood events, including evacuation procedures and the provision of emergency shelters.

Key stormwater assets for the HUC and Walton County are indicated in **Error! Reference source not found.** and **Error! Reference source not found.**, respectively. Stormwater structures and management processes in the county consist of stormwater outfall, water wells, weir, pollutant control boxes, inlets catch basins, pipes culverts, ditch conveyance swales, structures, pipes and open conveyance.

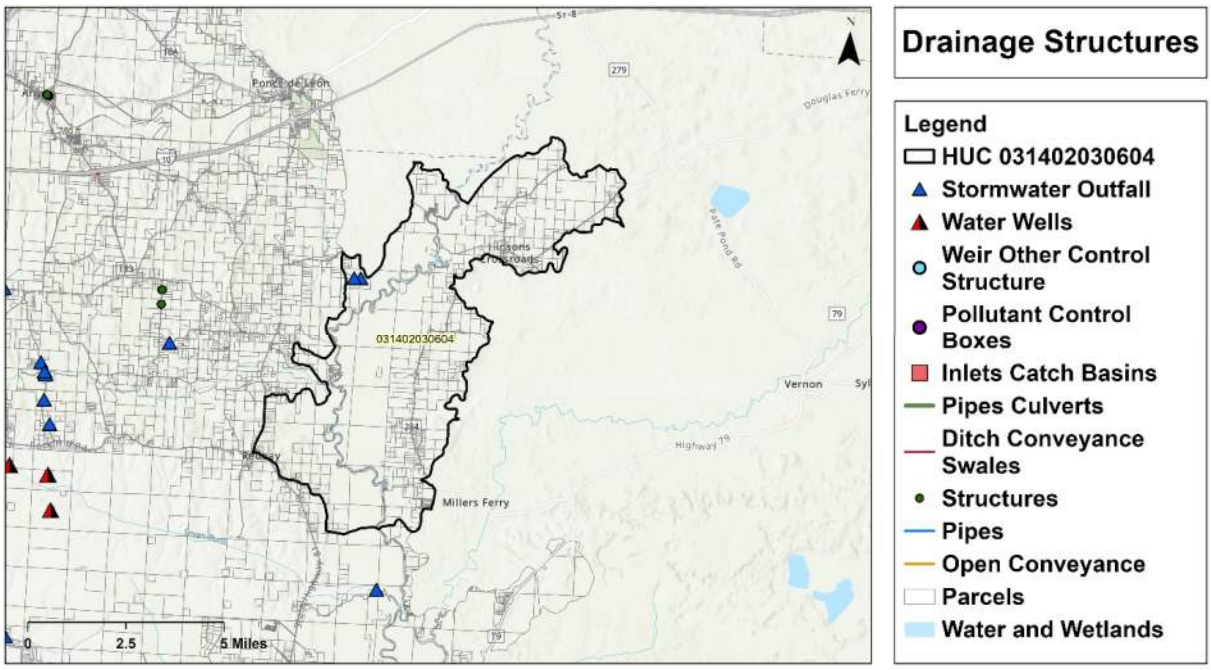

Figure 27. Stormwater Infrastructure for the HUC 031402030604. Processed by FAU.

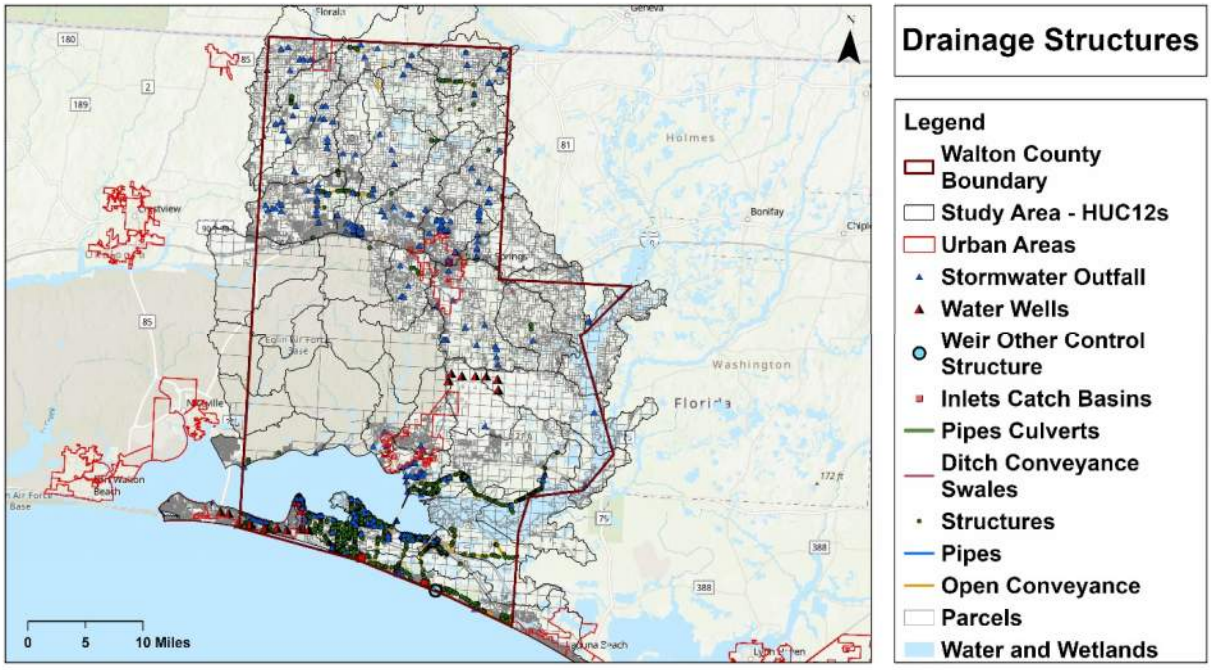

Figure 28.Stormwater Infrastructure for Walton County. Processed by FAU.

Although nature-based infrastructure might be installed, it is not certain. The stormwater system must maintain compliance with the stormwater regulations, which requires record-keeping, policy development, inspections and maintenance. The goals of such stormwater management may include:

- Best landscape practice;
- Control car washing contribution to pollution;
- Enforce the Stormwater Pollution Prevention Plan (SWPPP) by site evaluation, assessment, erosion and sediment controls, preventive maintenance, certification and inspection reporting for construction sites and city planning;
- Implement a hazardous material elimination system;
- Eliminate illicit dumping;
- Proactive and reactive catch basin inspections and maintenance;
- Street sweeping to control debris;
- Maintain swales to help prevent stormwater pollution flooding.

1.13 Data Gaps

FAU has developed comprehensive databases to address the information needed for the vulnerability assessment. These are included in **Error! Reference source not found.**. The data

can be used to model the impacts of flood routing during the storm of interest. As a result, the modeling pieces (discussed in Chapter 2) will include the following:

- Flood response model results (Cascade 2001)
- Flood risk/hazard mapping
- Vulnerability assessments to identify areas of concern for future repetitive losses

There is only one data gap for the area – existing stormwater infrastructure records are incomplete. However, for the purposes of this plan, this data gap does not limit the findings as there are two scales: 1) the sub-watershed level and 2) community hotspots. A neighborhood level vulnerability assessment will require the local infrastructure inventory.

Table 6. List of datasets collected by FAU as of List of datasets collected by FAU for the project (12/20/2020).

2.0 ASSESSMENT OF VULNERABLE AREAS

Defining flood risk due to compounding hydrographic influences is the central concern of this WMP. Modeling and assessment of vulnerability focused on the combination of a high-water table, heavy rains, and impervious conditions that can lead to localized nuisance flooding events. Through a previous survey with local officials, the number of days of continuous nuisance flooding that the public will tolerate before that flooding is considered destructive is about 4 days (E Science 2014).

For a large study area, small parts may actually be at risk. The point is to identify where further study might be needed. A screening tool accomplishes this goal applied to the sub-watershed scale to designate areas that are susceptible to periodic flooding events. Utilizing the information collected and analyzed in Chapters 1 and 2, and comparing to data in Chapter 3, vulnerability can be identified.

2.1 Historical and Existing Challenges

Walton County has faced various historical and existing challenges as well as natural hazards over the years. Some of these include:

- Hurricane and Tropical Storms: being situated along the Gulf Coast, Walton County is vulnerable to hurricanes and tropical storms, which can lead to damage to the built and natural environment, as well as poses risks to human and wild life.
- Coastal Erosion: The county's coastline is subject to erosion due to natural processes and human activities. Erosion can lead to the loss of beaches and threaten coastal structures and properties.
- Flooding: heavy rainfall, storm surges from hurricanes, and other factors can cause localized flooding, particularly in low-lying areas. Flood events can disrupt daily life, damage property, and impact transportation.
- Water Quality and Quantity: as in many coastal areas, managing water quality and maintaining an adequate water supply are ongoing challenges. Pollution from stormwater runoff and other sources can affect water quality, and groundwater resources need to be carefully managed to sustain the growing population.
- Wetland Loss: The county's wetlands face the threat of degradation and loss due to urban development and other human activities. Protecting these essential ecosystems is vital for maintaining biodiversity and mitigating flood risks.
- Urbanization and Development: Balancing the demand for development and growth with the preservation of natural habitats and resources is a persistent challenge. Unplanned

urbanization can lead to habitat destruction, increased runoff, and exacerbate flooding risks.

- Land Use and Zoning: Proper land use planning and zoning are essential to address issues related to population growth, infrastructure development, and natural hazard mitigation. Ensuring responsible development practices can help minimize risks.
- Invasive Species: Like many regions, Walton County faces the threat of invasive plant and animal species. These invasive species can disrupt local ecosystems, negatively impacting native flora and fauna.
- Sea-Level Rise: With rising sea levels due to climate change, coastal communities like Walton County's coastal areas are at greater risk of inundation and storm surges during extreme weather events.

The fast growth of the population and urban development in the coastal areas of the county exacerbates effort to protect open space for land percolation of water. While regulations are in place to reduce the influx of stormwater, the challenges will continue with development.

2.1.1 Existing Management Efforts in the Watershed

The county is under Northwest Florida Management District (NWFMWD) jurisdiction, which covers the Florida Panhandle region. The NWFMWD is responsible for managing and protecting water resources in its designated regions, which includes issues related to water supply, water quality, flood control, and natural resource conservation. Local governments have local stormwater utility infrastructure and planning/policy tools to reduce future flood potential. Most of the major projects to date have been focused on addressing the water quality issues and flooding due to extreme rainfall.

2.1.2 Critical Target Areas Identification

By modeling the HUC 031402030604 sub-watershed flood response to a series of rainfall events and sea levels (plus king tides), and further classifying flood risk as the probability of inundation, it is possible to identify critical target areas. These areas are particularly vulnerable to flooding and are subject to further study through a scaled-down modeling approach. The screening tool is first applied at the greater watershed level to provide an initial risk assessment focused on the hydrologic response to a rainfall event given the unique characteristics and features of the sub-watershed or study area. The process is discussed later in Section 2.2 with results presented in Section 2.4.

2.1.3 Potential Preservation Areas

Walton County boasts several areas with high biodiversity value. These areas include the unique coastal dune lakes, which support diverse ecosystems and contribute to water quality along the coast. Wetlands are crucial habitats that provide refuge for a variety of plant and animal species while acting as natural water filters. State parks like Topsail Hill Preserve and Grayton Beach State Park are valuable conservation areas with diverse coastal ecosystems. Additionally, preserving the Choctawhatchee River Basin is essential for the biodiversity of the region.

2.2 Vulnerability Maps

2.2.1 Screening Tool

The screening tool utilizes topographic data from various sources (Section 1.1), water table elevations (Section 1.2) and surface water gauges (Section 1.3) downloaded from the NWFWMD website, tidal information for coastal areas obtained from the NOAA Current & Tides website (Section 1.3), soil maps obtained from the USDA (Section 1.4), and another key dataset as described previously in Chapter 1. The design storms are discussed in Section 1.6. The reason this is critical is that to do any modeling (as required by the CRS program), a screening tool should be used to identify regions with a high risk of inundation based on multiple collected datasets and hydrological models. **Error! Reference source not found.** shows how the GIS layers interface in the tool and how they are combined for spatial analysis.

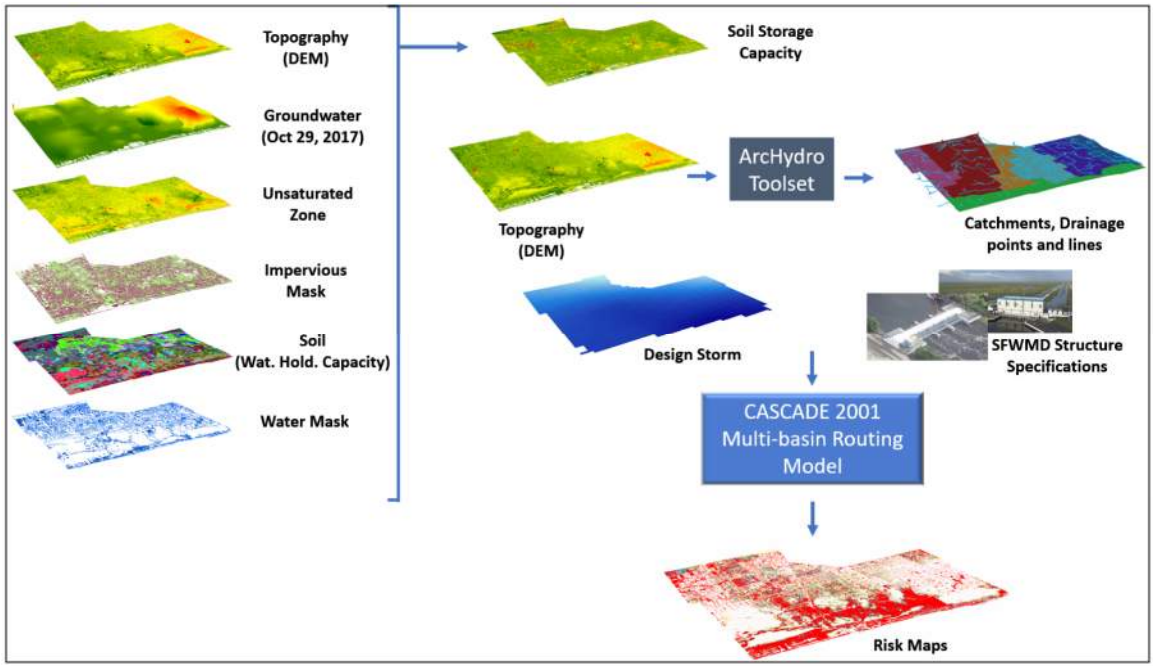

Figure 29. Screening tool methodology for creating flood risk maps.

The model chosen for this screening tool is Cascade 2001, which is a multi-basin hydrologic/hydraulic routing model developed by the SFWMD. The model permits the investigator to run different storm events to determine flooding scenarios. The boundaries are critical for basin studies and must be chosen carefully. The following data layers collected in the prior section are processed to develop the input files for Cascade 2001:

- Topography
- Soils
- Development intensity
- Groundwater elevations
- Surface water/Outlet locations

The software creates a glass box where water rises to a certain level and then decreases. Running the simulation requires defining the basin (HUC or sub-HUC) and input of the following data:

- Area
- Portion of area above a given elevation
- Initial groundwater stage
- Longest travel time for the runoff to reach the most distance point of discharge
- Ground storage as estimated from the USDA gridded National Soil Survey Geographic Database (gNATSGO)

Ground storage ≈ (Water holding capacity) × (Surface elevation – GW elevation)

= 2 × (AWS for a soil layer of 0-150 cm) / 150cm × (Surface elevation – GW elevation)

- Available water storage (AWS) for a soil layer of 0-150 cm
- Average amount of precipitation that can be stored in the soil layer

The output from the model is an elevation surface that can be used to develop a flood map for the study area (**Error! Reference source not found.**), which shows the spatial distribution of probabilities of flooding during the modeled 1-day 100-year storm event.

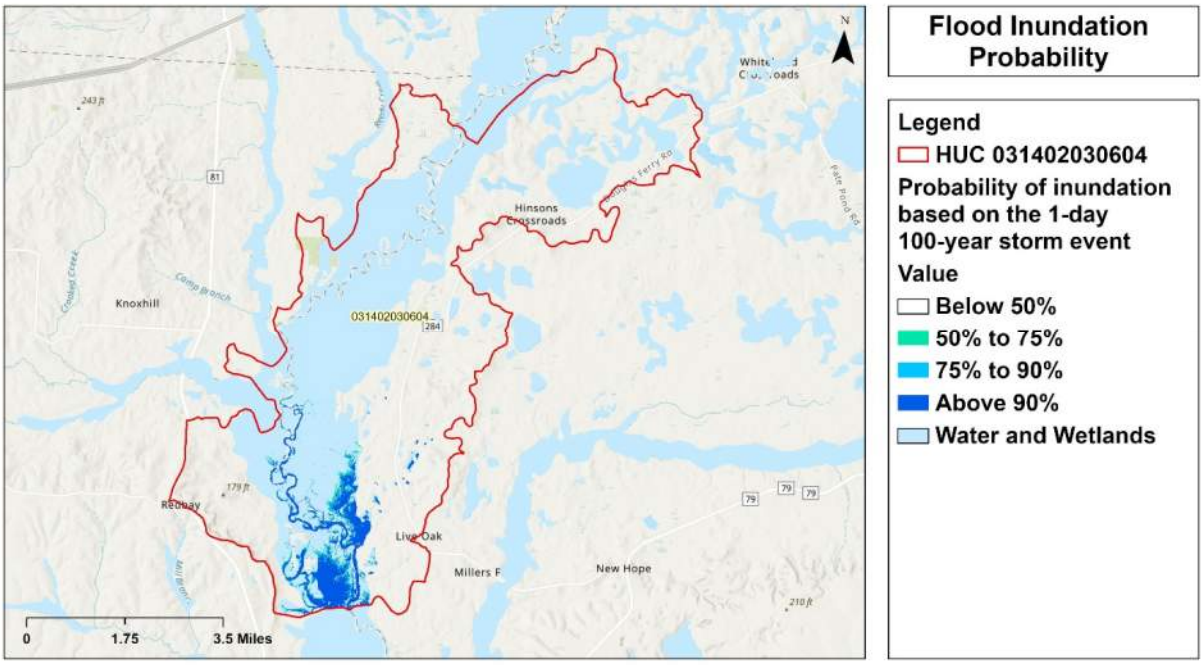

Figure 30. Probability of flood risk map during the modeled 1-day 100-year storm event for the HUC 031402030604, processed by FAU.

2.2.2 Identification of Vulnerable Areas

Given these assumptions and the Cascade 2001 outputs, the goal of this methodology is to produce a spatially-temporally quantified understanding of nuisance-destructive flood potential in the study area given observed values. Risk is a function of compounding geo-hydrological features, namely, surface water, groundwater, topography, build-out, and time of year. A GIS-based algorithm and spatial interpolation generated layers of the greatest observable hydrographic surfaces. These outputs were then compared with high resolution topographic LiDAR data to develop digital elevation models that reflect the observed risk landscape. These models can then be combined into Cascade 2001 to produce vector and volume information, in combination with soils, vegetation

and impervious surfaces, allowing the observed model outputs to be extrapolated into a more predictive context.

To evaluate flood vulnerability at this scale, the analysis starts with a binary flooding surface (0 = below 50% chance of flooding; 1 = above 50% flooding) based on output from the screening tool for a specified design storm. Next, attributes of that raster based on "VALUE = 1" query are extracted using *Extract by Attributes* tool. Then the *Batch Project* tool was used to map critical facilities data to the common coordinate system (NAD83 UTM Zone 17N), unit = meters. Then a field was added using *Add Field* for [PriorityTier] = assigned Tier #1-4 value from the DOR codes and [Area_sqmeter]. The critical facilities layers were then merged into a single layer to calculate the polygon geometry for [Area_sqmeter] using the *Merge* tool. Next, *Zonal Statistics as Table* is used to calculate the SUM of flooded values ("VALUE = 1") within each critical parcel. Output table has fields for SUM (i.e., total # of flooded pixels per critical parcel) and AREA in map units of square meters (since each pixel in the flooding surface has a cell size of 3-meters by 3-meters, each area is equal to the SUM value multiplied by 9 m^2). Using the *Join Field* tool, the SUM and AREA fields are joined to the merged critical facilities layer based on a key attribute, first renaming these fields for clarity (e.g., AREA_FLOODED_3d25y). Once all field data is included, the next step involves using *Export Table* to export the dataset as a CSV file. Note that non-flooded parcels have zero flooded area, so they receive a <Null> value from the zonal statistics tool. To replace null values with zeros, we use *Calculate Field* in the attribute table along with the following Python expression (replacing the respective field name): "0 if !AREA_FLOODED_3d25y! is None else !AREA_FLOODED_3d25y!". Next, the CSV file is saved as an Excel Workbook (.xlsx). The Range is converted to an Excel Table, and the columns are rearranged in the desired order. Finally, the "percent-flooded" columns are calculated as follows:

- PCT_FLOODED_3d25y = ([@[AREA_FLOODED_3d25y]]/[@[TotalArea_sqmeter]])*100
- PCT_FLOODED_1d100y = ([@[AREA_FLOODED_1d100y]]/[@[TotalArea_sqmeter]])*100

After this calculation, the table is sorted to show the higher priority tiers and higher percent-flooded values first. To reduce the number of critical facilities shown in the final table, a filter was created to show only critical facilities with 10% or more flooded area in the parcel during both storm events. Records with duplicate parcel ID numbers were removed from the table. The results of this procedure are discussed in Section 5.2 of this document.

With respect to dams and levees, for purposes of the NFIP, FEMA only recognizes systems that meet, and continue to meet, minimum design, operation, and maintenance standards that are consistent with comprehensive floodplain management criteria. The Code of Federal Regulations,

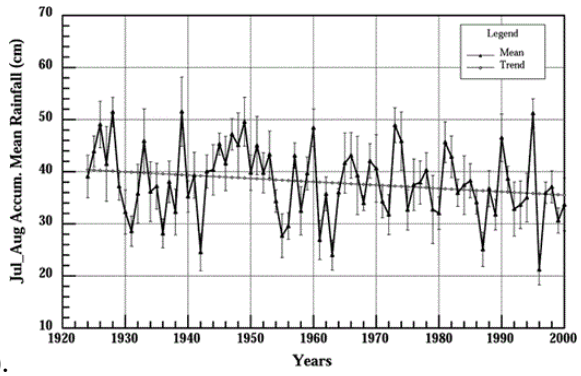
Title 44, Section 65.10 (44 CFR 65.10) describes the information needed for FEMA to determine if a levee system reduces the risk from the 1% annual chance flood. FEMA has accredited levees and Provisionally Accredited Levees (that have a specified timeframe to obtain the necessary data to confirm the levee's certification status). If a levee system no longer meets Section 65.10, FEMA will de-accredit the levee system and issue an effective FIRM showing the levee-impacted area as a SFHA. FEMA coordinates its programs with USACE, who may inspect, maintain, and repair levee systems. USACE has authority under Public Law 84-99 to supplement local efforts to repair flood control projects that are damaged by floods. Like FEMA, USACE provides a program to allow public sponsors or operators to address levee system maintenance deficiencies. Failure to do so within the required timeframe results in the levee system being placed in an inactive status in the USACE Rehabilitation and Inspection Program. Levee systems in an inactive status are not eligible for rehabilitation assistance under Public Law 84-99. There are no levees/dams listed in the sub-watershed study area.

2.3 Future Challenges of Sea Level Rise and Climate Change

Global observations from satellites and long-term data collection have made it possible to document and analyze patterns in the Earth's climate. Scientific analysis of the impact of these changes has helped to improve the understanding of future flood hazard driving forces and long-term impacts on human activities and watershed master planning (http://www.research.noaa.gov/climate/t_observing.html). Examples of impacts are rising global average air and ocean temperatures, increased and earlier snow and ice melt, shorter subtropical rainy seasons, shifted seasons, sea level rise and greater variations in temperature and precipitation (IPCC, 2013; Freas et al., 2008; Marshall et al., 2004; Bloetscher et al., 2010). Marshall et al. (2004) specifically focused on the Florida peninsula to predict changes in rainfall and warmer temperatures but interspersed lower low temperatures due to the potential loss of wetlands.

Future changes in climate will add to the existing impacts, at a time when the population of the state is expected to nearly double by 2030. Additional research and high-resolution climate modeling for the Florida peninsula and local jurisdictions is needed to help guide long-term plans like WMPs. Rainfall appears to be decreasing and temperatures rising (see **Error! Reference**

source not found.).



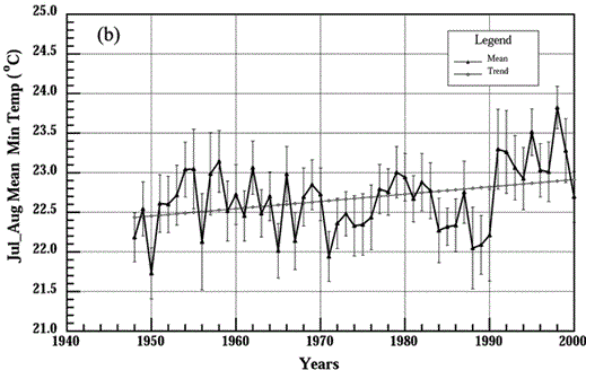


Figure 31. Change in average rainfall and change in average temp 1924 to 2000. Note the reversed trend, which means groundwater input variability is lessened. Source: Marshall et al., 2004.

Climate change is likely to: 1) threaten the integrity and availability of fresh water supplies and 2) increase the risk of flooding, not only in the low-lying coastal areas, but also in the interior flood plains. Other issues include a) saltwater intrusion, which may be intensified by sea level rise, b) prolonged droughts that will contribute to water supply shortages and wildfires, and c) heavier rains during the rainy season and higher hurricane storm surge, which may increase the risk due to flooding. More frequent and damaging floods are likely to become an ever-increasing problem as sea level continues to rise because of: a) increasing groundwater table elevations and surface water gage heights, b) reduced groundwater seepage through the aquifer to the ocean, c) increasingly compromised stormwater drainage systems, and d) more frequent inundation of barrier islands and coastal areas.

NOAA and IPCC (2013) predictions suggest that by 2100, global temperatures will be on the order of 2-3°C (3-5°F) higher and sea levels will rise by up to 3 feet. Accompanying these drivers are potential changes in storm frequency and intensity, desertification, population migration, ocean acidification and coastal flooding (IPCC, 2007), exacerbated by the land cover and land use changes, which are substantially impacted by the fluxes, timing and quality of precipitation (Adrians et al., 2003; Scanlon et al., 2005; Marshall et al., 2004; Salmun and Molod, 2006), and leading to changes in the timing of peak flows and volumes (Richey and Costa-Cabral, 2006).

The results of these climatic changes are likely to: 1) threaten the integrity and availability of fresh water supplies and 2) increase the risk of flooding, not only in the low-lying coastal areas, but also in the interior flood plains. Other issues include a) saltwater intrusion, which may be intensified by sea level rise, b) prolonged droughts that will contribute to water supply shortages and wildfires, and c) heavier rains during the rainy season and higher hurricane storm surge, which may increase the risk due to flooding. More frequent and damaging floods are likely to become an ever-increasing problem as sea level continues to rise because of: a) increasing groundwater table elevations and surface water gage heights, b) reduced groundwater seepage through the aquifer to the ocean, c) increasingly An outcome of these climatic patterns is that during the past 140 years, an increase in sea levels has been observed (Bloetscher, 2012), a worrying pattern since sea level rise is a permanent phenomenon, that can be catastrophic to low lying areas in the long-term. The question is how much and how soon? Various studies (Bindoff et al., 2007; Domingues et al., 2008; Edwards, 2007; Gregory, 2008; Vermeer and Rahmstorf, 2009; Jevrejeva, Moore and Grinsted, 2010; Bloetscher, 2010, 2011; IPCC, 2007; Heimlich et al., 2009) indicate large uncertainty in projections of sea level rise by 2100. Gregory et al. (2012) note that during the last two decades, the global rate of sea level rise has been larger than the 20th-century time-mean, and Church et al. (2011) suggested that the cause was increased rates of thermal expansion, glacier mass loss, and ice discharge from icesheets. Gregory et al. (2012) suggested that there may also be increasing contributions to global sea level rise from the effects of groundwater depletion, reservoir impoundment, and loss of storage capacity in surface waters due to siltation. Measurements of Florida's east coast (Maul, 2008) show an average rate of sea level rise of 2.27 ± 0.04 mm per year from 1915 to 1992 based on tide gauge readings. Analyzing the tidal gauge readings for Florida shows that:

1. Florida average sea level rise is 2.10 ± 0.49 mm/yr
2. All but one location is within the 95% confidence limit range (the exception is Panama City where there is evidence of submergence and other land-based issues)
3. None of the Florida sea level rise rates differ statistically
4. Average global sea level rise for 1920-2000 was 2.0 mm/yr – within 95% confidence limit for Florida locations

From 1929 to 1992, over eight inches of sea, with another 6 inches added since 1992, which is already having significant impacts on coastal communities where population growth has increased the need for improved flood management strategies (Bloetscher, 2008; Parkinson, 2010; Zhang et al., 2011, 2011a; NFIP, 2011; Schmidt et al., 2011; Warner et al., 2012).

As a result, the SFRCCC (2015) adopted USACE's methodology to derive scenarios of sea level change intermediate to high rates of sea level rise for years 2030 (3" to 7") and 2060 (9" to 24") as the consensus projection to guide future planning. The path keeps increasing – now 14 inches

since 1929 (**Error! Reference source not found.**) caused by thermal expansion of the ocean and melting ice caps (Jevrejeva et al., 2010; Vermeer and Rahmstorf, 2009). Sea level rise is a major concern in Florida, including Walton County, since the majority of the state's population live on the coast, involving most major commercial, residential, and economic enterprises. **Error! Reference source not found.** demonstrate the estimated sea level change for Panama City, considering the predictions of NOAA 2017. For NOAA high scenario SLR change scenario, the estimated level change is higher than 8 ft., while for the intermediate and low scenarios are about 3.9 feet and 1.7 feet respectively.

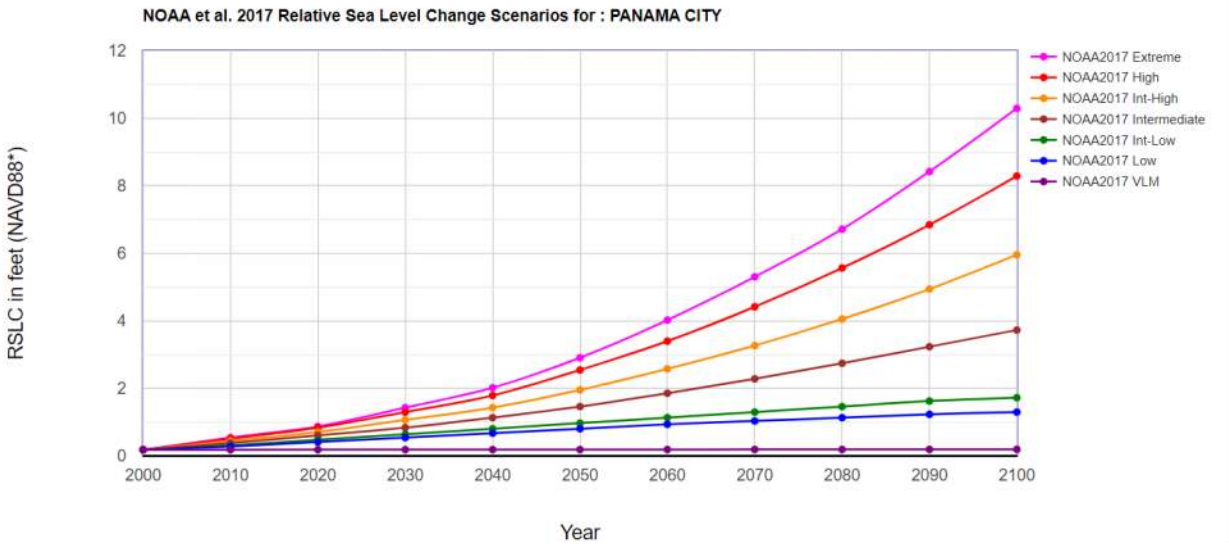

Figure 32. Relative Sea Level Change Scenarios for gauge 8729108, Panama City, FL. Source: NOAA, 2017 (https://cwbi-app.sec.usace.army.mil/rccslc/slcc_calc.html).

NOAA (2017) outlines five scenarios for sea level rise. The NFIP proposes the use of the intermediate high projection, which is 1.2 meters or 4 ft globally from current sea level elevations (**Error! Reference source not found.**).

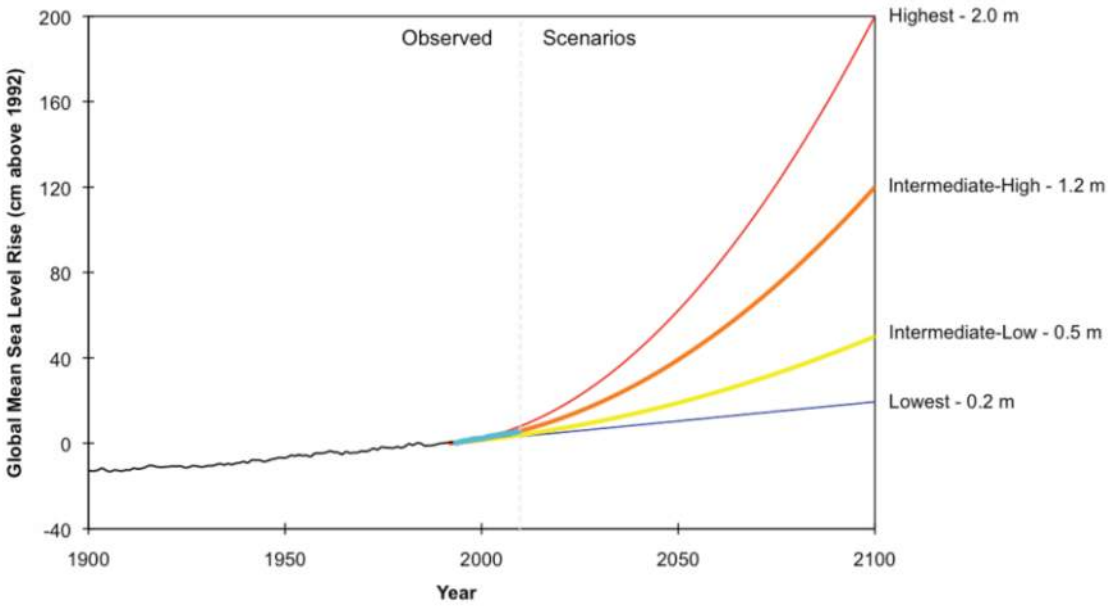

Figure 33. Graphic of global sea level rise projections from NOAA (2017). Source:https://tidesandcurrents.noaa.gov/publications/techrpt83_Global_and_Regional_SLR_Scenarios_for_the_US_final.pdf

As sea level rises, access to roads, bridges, rail, and transit could be at risk of flooding, causing the effects of sea level rise to spread indirectly throughout the entire transportation network, affecting the overall system performance. For example, the flooding of a critical road or facility access can cause a shifting of traffic flow causing congested conditions in other roadways that are not actually flooded. Since the roadway network would be unable to carry the traffic demand, the system would experience operational failure; as a result, causing travel times and delays. Moreover, the inundation of a critical access could cause transportation connectivity problems to essential infrastructure like ports or airports. Transportation infrastructure relies on the effectiveness of flood control and stormwater drainage systems for the transportation corridors. Road integrity relies on adequate drainage. The increased risk of severe flooding in Florida's low-lying terrain can adversely affect transportation infrastructure along the coastline; roads can be inundated, and roadway beds can be damaged. Sea level rise will cause increased water table levels (FDOT, 2012), as regional water tables cannot exist naturally below mean high tide (2 feet in Florida). Adding 3 feet of sea level rise on top of groundwater would compound the risk of flooding in low-lying areas. Road bases below 5 feet NVGD would become saturated under this scenario, likely causing premature base failure. As soil storage capacity is diminished due to rising groundwater elevations associated with sea level rise, the potential for more frequently flooded roadways would likely damage pavements (FDOT, 2012). Hence sea level rise must be accounted for in WMPs in coastal areas. To allow flexibility in the analysis due to the range of increases within the different time periods, an approach that uses incremental increases of 1, 2, and 3 feet of sea level rise is suggested for modeling. The increments can work as threshold values in planning

considerations in terms of allowing planners the ability to know ahead of time where the next set of vulnerable areas will be, to allow for a proactive response approach that can be matched to the observed future rates. Sea level rise is a major concern since nearly half the US population lives within 50 miles of the coast, involving most major commercial, residential, and economic enterprises. The effects of 5 ft of sea level rise, King tide, and 1-day 100-year storm event are shown in **Error! Reference source not found.**.

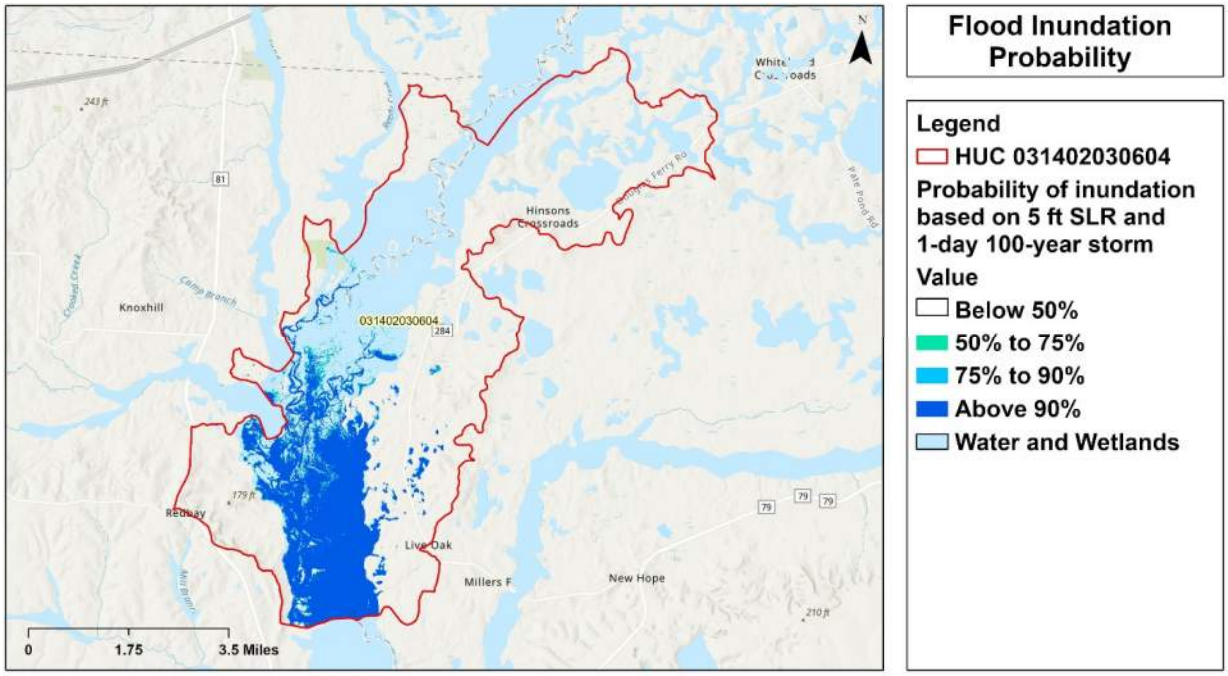

Figure 34. Flood Inundation Probability for a Sea level rise of 5 ft + 1-day 100-year storm event for HUC 031402030604 sub-watershed.
Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations.
Dark blue is area under 5 ft NAVD88 and potentially inundated at the 99th percentile tidal conditions. Processed by FAU.

2.4 Modeling Results

Error! Reference source not found. to **Error! Reference source not found.** are a series of maps that depict risk of flooding in the basin based on the following scenarios:

1. **3-day 25-year storm event**. Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 35)
2. **1-day 100-year storm event**. Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 36)

3. **1-day 10-year storm event.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 37)
4. **1-day 5-year storm event.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 38)
5. **Sea level rise of 1 ft + 3-day 25-year storm** (only coastal area and GW affected – GW layer rises 1 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 39)
6. **Sea level rise of 1 ft + 1-day 100-year storm** (only coastal area and GW affected – GW layer rises 1 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations storm (Figure 40)
7. **Sea level rise of 1 ft + 1-day 10-year storm** (only coastal area and GW affected – GW layer rises 1 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 41)
8. **Sea level rise of 1 ft + 1-day 5-year storm** (only coastal area and GW affected – GW layer rises 1 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 42)
9. **Sea level rise of 2 ft + 3-day 25-year storm** (only coastal area and GW affected – GW layer rises 2 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 43)
10. **Sea level rise of 2 ft + 1-day 100-year storm** (only coastal area and GW affected – GW layer rises 2 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 44)
11. **Sea level rise of 2 ft + 1-day 10-year storm** (only coastal area and GW affected – GW layer rises 2 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 45)
12. **Sea level rise of 2 ft + 1-day 5-year storm** (only coastal area and GW affected – GW layer rises 2 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 46)
13. **Sea level rise of 3 ft + 3-day 25-year storm** (only coastal area and GW affected – GW layer rises 3 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 47)
14. **Sea level rise of 3 ft + 1-day 100-year storm** (only coastal area and GW affected – GW layer rises 3 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 48)
15. **Sea level rise of 3 ft + 1-day 10-year storm** (only coastal area and GW affected – GW layer rises 3 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 49)
16. **Sea level rise of 3 ft + 1-day 5-year storm** (only coastal area and GW affected – GW layer rises 3 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 50)

17. **Sea level rise of 4 ft + 3-day 25-year storm** (only coastal area and GW affected – GW layer rises 4 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 51)
18. **Sea level rise of 4 ft + 1-day 100-year storm** (only coastal area and GW affected – GW layer rises 4 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 52)
19. **Sea level rise of 4 ft + 1-day 10-year storm** (only coastal area and GW affected – GW layer rises 4 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 53)
20. **Sea level rise of 4 ft + 1-day 5-year storm** (only coastal area and GW affected – GW layer rises 4 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 54)
21. **Sea level rise of 5 ft + 3-day 25-year storm** (only coastal area and GW affected – GW layer rises 5 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 55)
22. **Sea level rise of 5 ft + 1-day 100-year storm** (only coastal area and GW affected – GW layer rises 5 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 56)
23. **Sea level rise of 5 ft + 1-day 10-year storm** (only coastal area and GW affected – GW layer rises 5 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 57)
24. **Sea level rise of 5 ft + 1-day 5-year storm** (only coastal area and GW affected – GW layer rises 5 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 58)

In all scenarios, a considerable amount of flooding is noted at the river entrance to the HUC, extending to the wetland areas. As this basin connects to the ocean though Choctawhatchee River, SLR scenarios plays an important hole, implying a considered growth as the projected scenario of rising tides rises.

The design storm simulation determined that approximately 4.7% of the HUC total area or 1.75 mi² has a probability of inundation above 50% for all design storm, indicating that 1.75 mi² of the HUC would be expected to be inundated during all four storm event scenarios, as illustrated in **Error! Reference source not found.**.

Table 7. HUC 031402030604 expected inundated area by storm event.

Storm Event	Area with probability of inundation below 50% (Sq Mi)	Area with probability of inundation above 50% (Sq Mi)	Area with probability of inundation below 50% (%)	Area with probability of inundation above 50% (%)
3-day 25-year	35.65	1.75	95.3%	4.7%

1-day 100-year	35.65	1.75	95.3%	4.7%
1-day 10-year	35.65	1.75	95.3%	4.7%
1-day 5-year	35.65	1.75	95.3%	4.7%

2.5 Risk and Vulnerability

The screening tool modeling exercise from the prior section identified areas within the communities that are vulnerable to flooding. Higher priority concerns should be those properties or assets that are considered essential and need to be kept in service during a flooding event. All other improvements are local. To help with prioritization, the following is suggested:

- Tier 1 - Critical facility protection (water/sewer utilities, public safety, hospitals, schools, power, shelters)
- Tier 2 - Essential facilities (groceries, pharmacies, roadways)
- Tier 3 - Economic centers (protecting jobs)
- Tier 4 - At risk communities
- Tier 5 - Other urban/suburban property
- Tier 6 - Agriculture/public property/vacant/undeveloped

Error! Reference source not found. outlines the priority of land use based on DOR land use codes from the property appraiser's office and assigns an associated priority level to each parcel. Note that for residential property, identifying at-risk communities (income, age, disability, health) requires a further drilldown to the neighborhood level (i.e. wealthy neighborhoods with few older, poor health individuals would have a lower priority than at risk communities, which generally have lower value housing and denser development). In the latter case, more people are impacted, and those people have less ability to mitigate risk. Based on these priorities, the relative risk priority DOR land use codes were evaluated based on a scale of 1 to 6, where 1 is higher priority (more vulnerable) and 6 is the least priority (least vulnerable).

Table 8. Priority of Land Use based on (DOR) land use codes. Processed by FAU.

101	Parcels With no Values (ROW - avenues, highways, arterials)	2
102	Parcels With no Values (Water)	6
103	Parcels With no Values (Rail)	2

Having assigned the risk priority from 1 to 6 in the DOR codes and the percentage of the parcel that floods during the applicable design storm, properties that are more critical to the function of the community can be identified. The methodology is to first convert the DOR code priority tier to its inverse scale by the following equation:

Consequence of risk factor = 7 – DOR Code Priority Tier

The flood risk factor from the screening tool is interpreted based on flooding probability. We take all parcels in tiers #1-4 that have a greater than 50% chance of flooding during a particular design storm and calculate the percent of the parcel that would flood during that event. The percentage is converted to a 6-point scale termed as the Flood Risk Factor, shown in **Error! Reference source not found.**.

Table 9. Flood Risk Factor Classification.

Percent of Parcel Flooded	Flood Risk Factor
90-100%	6
80-89%	5
70-79%	4
60-69%	3
50-59%	2
<50%	1

The priority is further developed by assigning 75% of the importance to the consequence of flooding and 25% importance to flood risk, or three times the importance to the consequence of flooding to come up with a composite score as follows:

Flood Risk Factor × 25% + Consequence of Risk Factor × 75% = Composite Score

Example: 1 × 25% + 6 × 75% = 4.75

Those higher priority properties that received the higher composite score are where the mitigation strategies and financial resources should focus first.

2.5.1 Results

Error! Reference source not found. to **Error! Reference source not found.** depict the HUC 031402030604 sub-watershed priority of land uses showing the critical facilities that should receive priority. The first map (Figure 59) exclusively displays critical facility parcels The first map (**Error! Reference source not found.**) exclusively displays critical facility parcels within the HUC without any flooding. The second map (Figure 60) overlays critical facilities onto the 1-day 100-year storm event scenario, while the third map (**Error! Reference source not found.**)

represents the same overlay within the context of 5 feet of sea level rise (SLR) combined with the 1-day 100-year storm event. **Error! Reference source not found.** is a mosaic showing critical facilities overlaid in the 5 feet SLR + 1-day 100-year storm event for the whole county.

Additionally, **Error! Reference source not found.** and **Error! Reference source not found.** illustrate the composite score for the HUC, which is the result of the calculations explained above, pinpointing parcels that should be prioritized. It considers only parcels classified as 1 to 4 tiers, and within the 50% probability of inundation area. **Error! Reference source not found.** represents the calculation for composite score based on 1-day 100-year storm event, while **Error! Reference source not found.** shows the calculation for composite score for the same storm event, but including a 5 feet of Sea Level Rise scenario. **Error! Reference source not found.** shows the same area zoomed out.

Please note that the composite score results display outcomes exclusively for parcels within the flooding path area. Consequently, for parcels outside this flooding path, the composite results will be null. The composite score combines the flooding path area with the land use priority results to identify the most vulnerable areas deserving of priority.

2.5.2 Solutions

Chapter 5 of the Watershed Master Plan for Walton County describes a list of possible gray and green stormwater strategies to combat flooding that can be implemented as solutions for the county. The same solutions can also be applied at the HUC level, including HUC 031402030604. A summary of these flood mitigation strategies is listed in **Error! Reference source not found.**. For more detailed information, please see Chapter 5-5.3 (Solutions).

Table 10. List of possible gray and green stormwater strategies to combat flooding.

Strategy Class	Implementation Strategy	Applications	Benefits	Cost	Barriers to Implementation
Green	Rainwater harvesting	Local, small scale, easily implemented in developed areas	Protects property, treats runoff	Under $5,000	Limited volume disposed of, so many are needed, maintenance
Gray	Pervious paving	Parking lots, patios, driveways, anything except paved roads due to traffic loading	Reduces roadway and parking lot flooding	$10-20/sf, requires bumpers and sub-base to maintain paver integrity	Must be maintained via vacuuming or the perviousness fades after 2-3 years
Green	Detention	Common for new development, but difficult to retrofit; limited to open areas	Removes water from streets, reduces flooding	$200K/ac	Land availability, maintenance of pond, discharge location Uses up land that could otherwise be developed
Gray	Exfiltration Trench	Any low-lying area where stormwater collects and the water table is more than 3 ft below the surface; densely developed areas where retention is not available, roadways	Excess water drains to aquifer, some treatment provided	$250/ft	Significant damage to roadways for installation, maintenance needed, clogging issues reduce benefits
Gray	Central sewer installation	All areas where there are septic tanks. Mostly a water quality issue	Public health benefit of reducing discharges to lawns, canals, and groundwater from septic tanks	$15,000 per household	Cost, assessments against property owners, property rights issues
Green	Flood prone property acquisition	Regional agency - could be any low-lying areas	Removes flood prone areas from risk	$2K-$100K/ac depending on whether it is already developed	Difficult to implement if occupied, issues with willing sellers, cost, lack of funds for acquisition

Strategy Class	Implementation Strategy	Applications	Benefits	Cost	Barriers to Implementation
Gray	Pump stations	Any low-lying area where stormwater collects, and there is a place to pump the excess stormwater to such as a canal; common for developed areas	Removes water from streets, reduces flooding	Start at $1.5 to 5 million each, number unclear without more study	NPDES permits, maintenance cost, land acquisition, discharge quality
Gray	Armored sewer systems	Any area where gravity sanitary sewers are installed	Keeps stormwater out of sanitary sewer system and reduces potential for disease spread from sewage overflows	$500/manhole	Limited expense beyond capital cost
Gray	Sea walls	Barrier islands and downtown coastal areas	Protects property	$1200/ft	Private property rights, neighbors
Policy	Changes in land use	Applicable universally	Achieves flood risk mitigation by adjusting permitted land use	Low but may incur private property rights conflicts and litigation	Private property rights conflicts and litigation
Gray	Roadway base protection	Low-lying areas, coastal communities	Protects roads and access routes	$1 million per lane-mile	Cost, adjacent properties become uninsurable
Policy	Enhanced elevation of buildings	Developers would implement this for new construction	Reduced flood risk	Varies	Potential issues with building structure or latticework, and existing homes that are not elevated

2.5.3 Impacted Adjustment Areas

In the evaluation of flood risk management strategies within the framework of the National Flood Insurance Program Community Rating System (CRS), the concept of impact adjustment plays a pivotal role in determining the extent to which CRS-credited activities or elements influence the vulnerability of a community's Special Flood Hazard Area (SFHA) and the structures located within it. It's important to note that while the usual results of impact adjustment are related to the SFHA area, in this specific analysis, it was used 1-day 100-year storm event inundation area performed by FAU instead.

In this context, the following table presents a breakdown of the impact adjustment calculations for a 1-day 100-year storm event inundation. The values are expressed in acres and depict the areas of interest as well as the deductions considered in the evaluation process.

The outcomes of these calculations provide valuable insights into the impact adjustment scenarios:

With ALL State Lands:

This scenario reflects the remaining inundation area after accounting for deductions A, B, and C. It represents the effect of CRS-credited activities without considering the influence of state lands in managing flood risks.

With NO State Lands:

In this case, the remaining inundation area is determined by considering all deductions, including state lands (both open space and not open space– see **Error! Reference source not found.**).

These calculations highlight the dynamic nature of impact adjustment within the CRS framework. By accurately gauging the influence of individual elements, the system ensures that credit allocations align closely with a community's efforts in flood risk mitigation.

Table 11. Impacted Adjustment Areas for HUC 031402030604. Processed by FAU.

AREAS	**ACRES**
HUC-12 Sub-watershed: 031402030604	23937.53
All of the 1-day 100-year storm event inundation	**1122.11**
Subtract	
A. Bodies of Water in 1-day 100-year inundation > 10 acres	926.34
B. Federal Land in 1-day 100-year inundation > 10 acres	0.00
C. Reservation/Tribal Land in 1-day 100-year inundation > 10 acres	0
D. State Land in 1-day 100-year inundation > 10 acres that is open space	133.86
E. State Land in 1-day 100-year inundation > 10 acres that is NOT open space	3.42
The remainder is either:	
With ALL State Lands: All of the 1-day 100-year inundation minus (A+B+C) or	195.78
With NO State Lands: All of the 1-day 100-year inundation minus (A+B+C+D+E)	58.50

2.5.4 Repetitive Loss Property Map

A Repetitive Loss (RL) property is a building that has had two or more loss or damage due to a specific hazard, such as floods, hurricanes, or other natural disasters, over $1,000 each, paid by the National Flood Insurance Program (NFIP) within any ten-year period since 1978. There are more than 122,000 RL properties in the nationwide (FEMA, 2005).

These data are essential for assessing the vulnerability of certain areas to recurrent losses and for developing strategies to mitigate the risks. However, due to privacy concerns, the data cannot be openly shared with the public. For this reason, the data were converted into a hot spot analysis map. These maps, instead of identifying the specific location of the repetitive loss properties, highlight clusters of repetitive loss claims and areas where the probability of repetitive losses is higher than would be expected by random chance. In other words, it helps pinpoint locations that have a higher concentration of properties prone to repetitive losses. **Error! Reference source not**

found. indicates the results from hot spot analysis in point data, showing aggregated counts, and raster data, showing the estimated probability of repetitive loss.

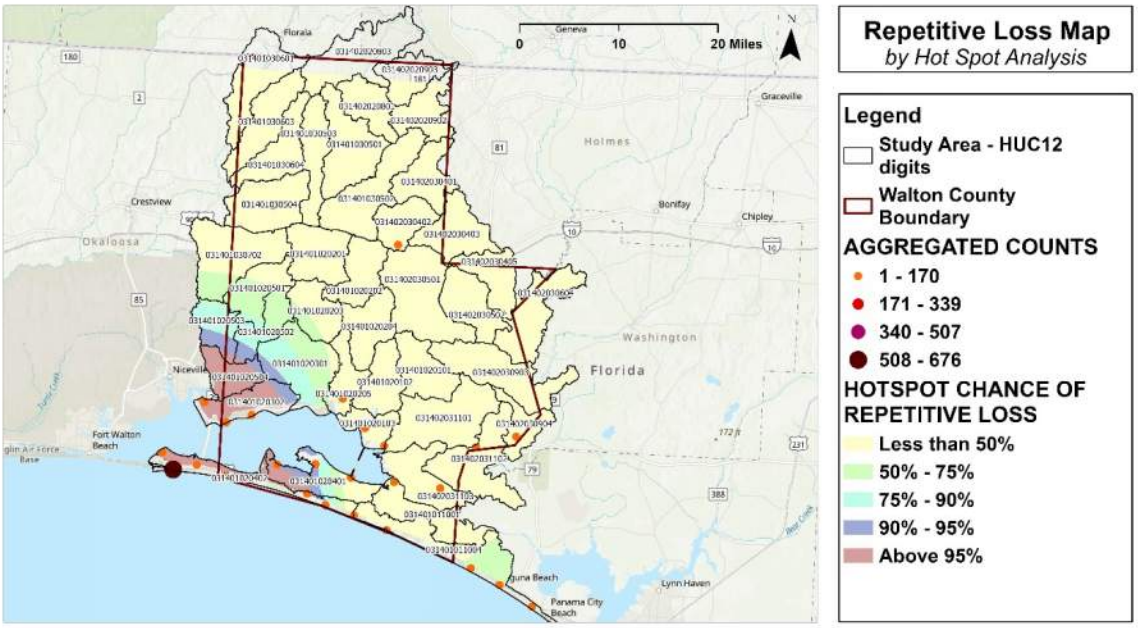

Figure 66. Repetitive Loss map for Walton County by Hot Spot Analysis. Processed by FAU.

2.5.5 Priority Projects

Although there are some parcels falling within tiers classification 1 to 5 priority of land uses within the basin, fortunately only a few of them are within the flooding zone. Consequently, when considering the composite score, it is notable that most of the results are null. There are only five exceptions within the basin considering both 1-day 100-year storm event and 1-day 100-year + 5 feet SLR scenarios: one road (River Rd) within score 3-4, and four mobile home, with score below 3.

X.0 EXECUTIVE SUMMARY

The goal of the appendices to the watershed plan are to outline the issues associated with the individual HUC12s that contribute or impact the community's flood vulnerability and there for its flood protection efforts. Floodplain analysis includes developing a watershed model and identifying associated inundation polygons. It builds upon information generated from the watershed evaluation so that planning and management decisions can be formulated.

This appendix describes the issues and modeling associated with one of the HUC12s that affects Walton County. In developing the County-wide plan, this HUC 12 was analyzed so as to determine how it brings or removes floodwaters from the County. For the NFIP process the goal is to analyze all communities at the HUC12 level. From a community perspective the HUC12 is less useful to residents than a community-wide plan. Hence in all cases the HUC12 results were mosaicked into the community-wide plan. Details can be found in the HUC12 appendices, some of which were brought into the community plan.

To reduce redundancy, information of the plans, ordinances, policies and regulations were rolled up to the community-wide plan and will not be repeated in the appendices. Likewise, the community wide mapping was parced for HUC12 use.

1.0 WATERSHED CHARACTERIZATION

In this section, key aspects of the watershed are characterized. This is important for later being able to identify the most vulnerable areas and to mobilize resources to implement an action plan. Understanding the characteristics of the watershed involves gathering existing information and data sets from previous planning efforts. It is important to note that this step is iterative and ongoing as new data are generated and projects are implemented and monitored.

To assess the historical and current conditions of the study area, the following existing data sets that characterize the physical and natural features of the watershed were obtained for each HUC-12 sub-watershed in the study area:

- Topographic data (LiDAR)
- Relevant waterway locations
- Groundwater levels
- Soils data
- Land uses including vacant land, wetlands, impervious, etc.
- Precipitation records
- Catchment delineations for flood routing

In addition, the FEMA flood maps must be obtained, and the storm of interest must be identified for screening purposes (1-day 2-year, 5-year, and 100-year events as well as the 3-day 25-year storm event to achieve class 4 in the CRS Manual). In developed areas, many sources of data are already available – the key is putting the key datasets in a format that can queried for screening to identify the priority areas of the watershed. Table 6 is a summary of datasets available at cwr3.fau.edu that were used to construct this plan.

This watershed master plan is a drilldown of the larger Walton County TMDL region, which involves 42 HUC 12-digit sub-watersheds (**Error! Reference source not found.**). **Error! Reference source not found.** shows Walton County Drainage Network and the location of urban areas (cities and towns). In **Error! Reference source not found.**, HUC-12 digits (031402030903) is highlighted among all the HUCs to help identifying its location. (Figure 3).

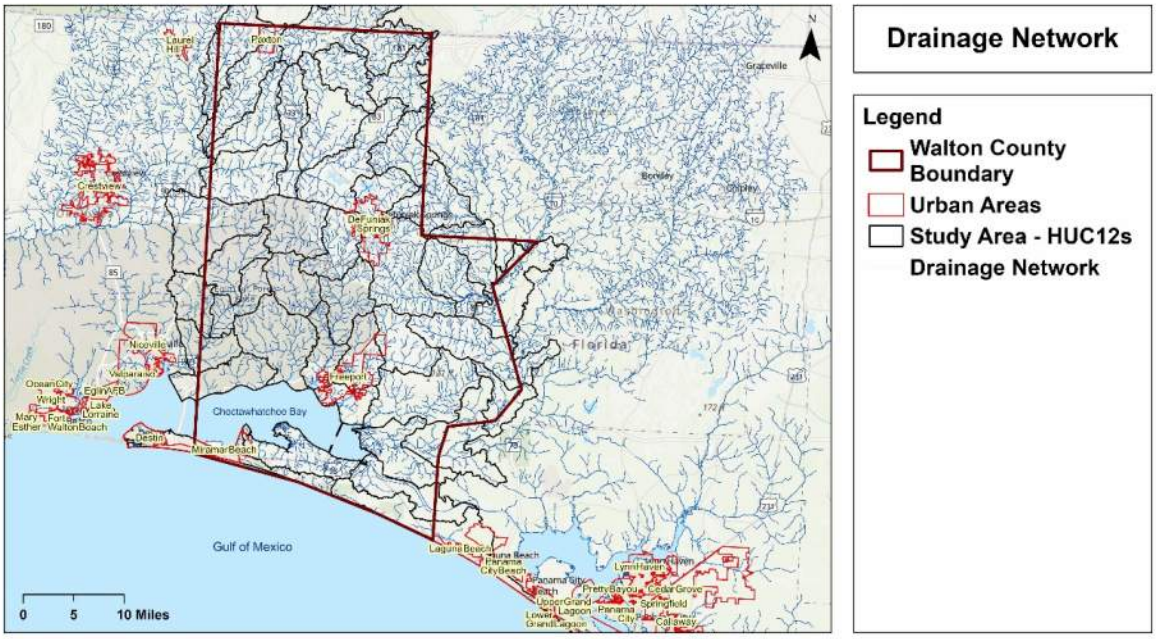

Figure 2. Walton County Drainage Network and urban areas (cities and towns), processed by FAU.

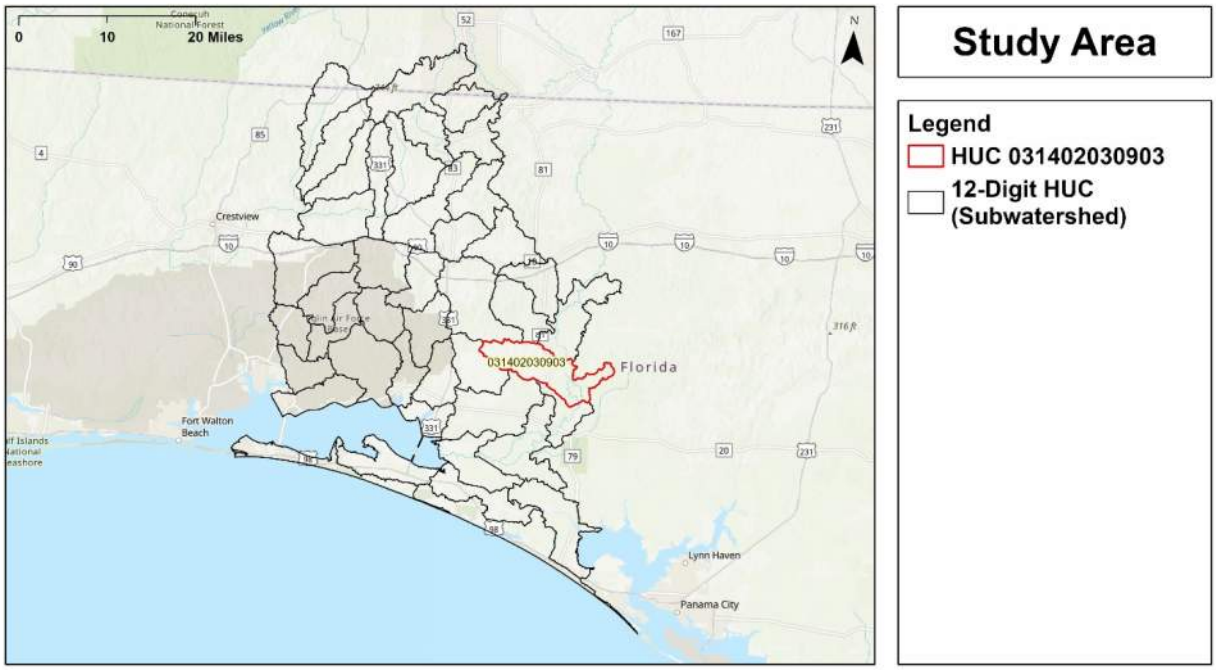

Figure 3. HUC 031402030903 sub-watershed location.

Located in the northwestern region of Florida, Walton County has 1,037.7 square miles of land and it is the 12th largest county in Florida by area, while also sits the highest point in the state, with a height of 345 feet in its northern end. With a population of 75,305 residents according to the 2020 census and an estimate population in July of 2022 of 83,304, the county has experienced

consistent growth within the past several years, driven by factors such as tourism, retirement migration, and regional population dynamics. The county was the residence for 55,043 people according to Census 2010, which leads to a percent change of 36.8% in 10 years, between 2010 and 2020, and a percentage change of 10.6% in two years, between 2020 and 2022 (United States Census Bureau).

The surge in population, particularly in the southern part of Walton County, has resulted in a corresponding expansion of infrastructure to cater to the growing needs. Essential facilities such as potable water systems, wastewater treatment plants, electrical utilities, roads, and schools have been developed to support this increasing population. However, the infrastructure expansion has brought about a significant change in the natural environment. Prior to the existing development , tropical cyclone impacts would be mitigated by natural barriers such as vegetated sand dunes, wetlands, and deserted beaches, which would absorb some of the destructive forces. Now, with the proliferation of costly infrastructure and residential dwellings in coastal areas, these storms pose a higher risk of potential damage. The very areas where development is occurring are becoming more vulnerable to the impact of severe storms, highlighting the importance of considering and implementing adequate measures to address potential storm damage in these coastal regions (Walton County Local Mitigation Strategy Plan, 2015).

Demographically, Walton County presents a heterogeneous age distribution, encompassing a blend of younger and elderly cohorts. The median age of approximately 44 years reflects the presence of both younger families and retirees seeking a serene and picturesque environment. Ethnically, the county' population is predominantly White with smaller yet notable populations of Hispanic/Latino, African American, and other racial/ ethnic groups.

Economically, the tourism sector stands as a dominant force in Walton County, constituting 23.4 percent of the workforce, according to Walton County Economic Development Alliance in 2011, due to its renowned beach destinations, such as Santa Rosa Beach, Miramar Beach, and the New Urbanist Communities of Seaside and Rosemary Beach. Following closely behind is the trade, transportation & utilities sector, accounting for 20.3 percent of employment, while construction stands at 10.0 percent in third place. Education, health care services, and public administration also play significant roles within the top five employment sectors, reflecting the diversified economic landscape of the county (Walton County Local Mitigation Strategy Plan, 2015).

The natural environment in Walton County contributes to its distinctive appeal to visitors and tourists. The county's coastal environment along the Gulf of Mexico showcases picturesque vistas, including white sand beaches, undulating dunes, and coastal dune lakes. These lakes, a rarity worldwide, provide unique ecological habitats. Walton County is also committed to environmental conservation, with designated protected areas comprising state parks, forests, and wildlife management zones. These preserved landscapes offer abundant opportunities for recreational activities, including hiking, fishing, and birdwatching.

The presence of wetlands and waterways further enhances the natural attributes of Walton County. Various rivers and creeks alongside Choctawhatchee Bay permeate the landscape, fostering diverse ecosystems and serving as crucial habitats for a wide range of wildlife species. This rich natural heritage encourages exploration and nurtures an appreciation for the environment.

DeFuniak Springs serves as the county seat and boasts a diverse economy. Anchored by sectors such as healthcare, education, retail, government services, and a thriving small business community, DeFuniak Springs offers a range of employment opportunities. Surrounded by the natural beauty of forests, lakes, and wetlands, the city enjoys the presence of Lake DeFuniak, a noteworthy natural resource. With a population of approximately 5,100 residents, DeFuniak Springs is a vibrant city featuring a mix of economic activities. The land area of DeFuniak Springs is approximately 12.6 square miles (32.7 square kilometers).

Freeport boasts a diverse demographic profile, and a developing economy. The city is situated along the shores of Choctawhatchee Bay, which provides opportunities for recreational opportunities and supports local ecosystems. Surrounded by lush forests and intersected by waterways, Freeport enjoys a rich environmental setting. In terms of economics, Freeport's economy is in a phase of growth and diversification, with sectors including healthcare, education, retail, and small businesses. The city is also strategically positioned for future economic expansion due to its proximity to major transportation corridors. Demographically, Freeport is a close-knit community with a population of approximately 2,600 residents, comprising a mix of permanent residents, retirees, and individuals seeking a suburban or rural lifestyle. The city reflects a diverse demographic composition, showcasing a variety of cultures, and backgrounds. Freeport occupies a land area of about 13.6 square miles (35.3 square kilometers)

Further along the coast, Miramar Beach stands as a coastal gem known for its tourism and hospitality industry. Luxury resorts, vacation rentals, gourmet restaurants, high-end retail shops, and entertainment venues thrive within this bustling city. Miramar Beach's main attraction lies in its stunning white sand beaches along the Gulf of Mexico, providing endless opportunities for beach activities and water sports. Its boundaries extend into neighboring Okaloosa County, attracting a blend of permanent residents, vacation homeowners, and rental property occupants. Miramar Beach, including its neighboring areas, covers an estimated land area of around 4.7 square miles (12.2 square kilometers).

Continuing along the Gulf Coast, we encounter Santa Rosa Beach. This coastal community is renowned for its vibrant tourism industry, offering a plethora of accommodations ranging from upscale resorts to charming vacation rentals. Its demography reflects a mix of permanent residents, seasonal visitors, and individuals seeking a coastal lifestyle, resulting in a diverse and dynamic community. Santa Rosa Beach spans a larger area compared to other cities in Walton County, with an estimated land area of approximately 31.2 square miles (80.8 square kilometers).

A summary of the existing CRS classifications for the communities in the study area is listed in **Error! Reference source not found.**. No cities in Walton County are listed in the FEMA Community Rating System Eligible Communities.

Table 1: Community Rating System for Walton County. Effective April 1, 2023.

Community #	**Community Name**	**CRS Class Rating**	**Premium Discount for SFHA**	**% Discount for Non- SFHA**	**Status**
120317	Walton County	6	20%	10	Cycle

(Source Data: FEMA)

Figures 12 and 13 is the county-wide report show the current and projected land use for the County. Based on the 2017 future land use for Walton County, only 7.07% of the land use in the county is urban and built up, and water/wetlands makes up 29.16% of the land use. The majority of land is upland forest, with 48.3%, as shown in **Error! Reference source not found.**.

Table 2. Land Use in Walton County (Prepared by FAU from future land use map) versus land use in the entire watershed

Level 1 Land Use-Land Cover Type	**Area (Acres)**	**Percentage of Total**
Agriculture	52958.94669	7.17%
Barren Land	9242.05986	1.25%
Rangeland	40326.66002	5.46%
Transportation, Communication, and Utilities	11815.69287	1.60%
Upland Forest	356796.0541	48.30%
Urban and Built-Up	52194.79061	7.07%
Water	61593.80508	8.34%
Wetlands	153759.9055	20.82%
Total	**738687.9147**	**100.00%**

(Source Data: (NWFWMD 2017)

Walton County has a history of flooding and has implemented various measures for flooding mitigation over the years (see section 1.12 for more details). The County has experienced flooding primarily due to heavy rainfall events and proximity to large water bodies such as the Gulf of Mexico, Choctawhatchee Bay, and numerous rivers and creeks. The topography of the region, with low-lying areas in the coastal areas and wetlands, also contributes to flood vulnerability. The proximity to the ocean (Gulf of Mexico) makes the county vulnerable to sea level rise. Over the years, Walton County has faced multiple flooding incidents, including:

- March 1997: Heavy rainfall led to significant flooding throughout the county, resulting in property damage and road closures.

- April 2009: Intense storms caused widespread flooding, damaging homes and infrastructure and resulting in the declaration of a state of emergency.
- April 2014: Heavy rainfall caused severe flooding, leading to the evacuation of some residents and the closure of roads.

Today, the goal of a stormwater management system in many communities is to keep the community as a place to live and do business while limiting risk from damage due to flooding. The short-term impacts from stormwater include flooding in low-lying areas and standing water in areas with limited soil storage capacity. Less common, but of increasing frequency, is the potential for extensive inundation of some areas, especially low-lying areas, during periods with high groundwater levels and groundwater impacted by sea level rise. As a result, there is a need to understand the economic impact of flooding events and to create cost-effective stormwater infrastructure and policy solutions to protect property. This means preserving as much property and economic activity as possible without disrupting current activity or expending funds on inappropriate projects with limited long-term or social value.

1.1 Surface Topography

Topography is a key parameter that influences many of the processes involved in flood risk assessment, and thus, up-to-date, high-resolution, high-accuracy elevation data are required. In order to meet the requirements for FEMA Risk Mapping, Assessment, and Planning (RiskMAP), 1-meter (2015 to present) and 1/9 arc-second (~ 3-meter) (2010 -2015) LiDAR DEMs were acquired. The 1 m × 1 m LiDAR tiles were kriged to create a topographic map of the study area (**Error! Reference source not found.**). This accuracy meets the 3DEP Quality Level 2 vertical root mean square error accuracy threshold of ±10 cm for FEMA (Arundel et al., 2015). The LiDAR used for this basin was 2016.

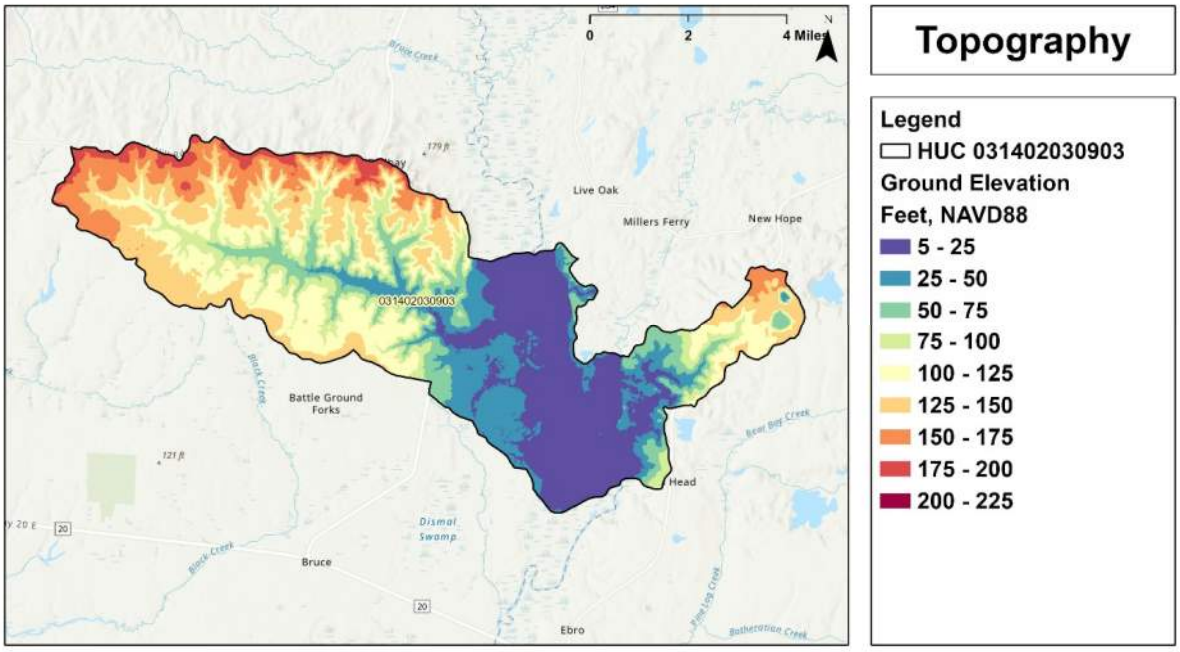

Figure 4. Topographic map of the HUC 031402030903 sub-watershed, processed by FAU

1.1.1 Geomorphological Considerations

Walton County's coastal area is characterized by the presence of barrier islands, extensive sandy beaches, and coastal dune systems. These features are influenced by the dynamic processes of wave action, tidal currents, and wind-driven sediment transport. The shoreline is subject to natural changes, including erosion and accretion, which significantly shape the coastal geomorphology. Inland Walton County exhibits a mix of wetlands, forests, rolling hills, and rivers. These landforms are influenced by a combination of factors, including underlying geology, fluvial processes, and the region's hydrological regime.

Like many areas in Florida, Walton County is underlain by limestone formations. The specific composition and properties of these limestone formations in Walton County may vary. However, limestone is generally known for its porous nature, which allows for the absorption and storage of water. Underground aquifers within the limestone formations can hold significant volumes of freshwater, contributing to the region's water resources.

For context, the FIRM panel index of HUC 031402030903 sub-watershed is shown in **Error! Reference source not found.**.

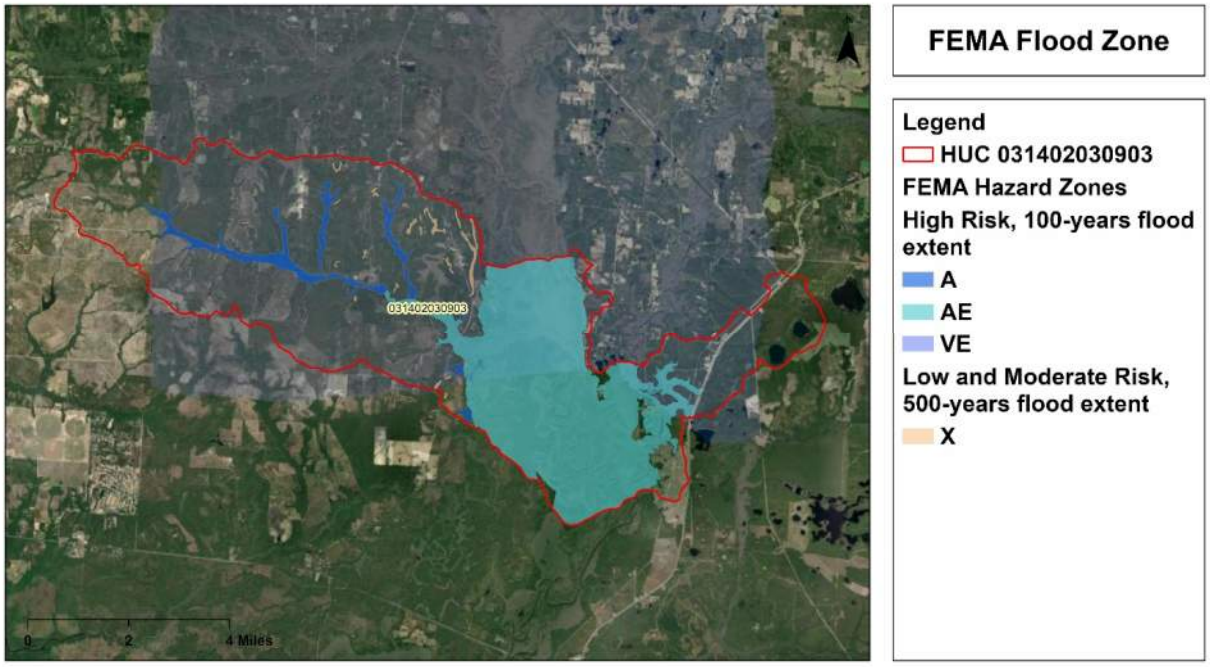

Figure 5. FEMA Flood Zone map (2020) for HUC 031402030903 sub-watershed, processed by FAU.

1.1.2 Waterway Features

In Walton County, Florida, the waterway features are primarily influenced by the presence of rivers, creeks, bayous, and the proximity to the Gulf of Mexico. To the south of Walton County lies the Gulf of Mexico. Sandy beaches, barrier islands, and the open waters of the Gulf itself characterize the coastline along the Gulf. The Gulf of Mexico influences the coastal processes, including wave action, tidal currents, and sediment transport along the shoreline. The combination between sea level rise and King tide would have detrimental consequences for the county costal area, including the sub-watershed 031402030903 as it will reach the area thought Choctawhatchee Bay.

Walton County is home to several rivers and creeks that meander through its landscape. These waterways provide drainage for the inland areas and contribute to the overall hydrological system. Examples of significant rivers in the county include the Choctawhatchee River and the Shoal River. In addition, Walton County features bayous and estuaries that connect inland water systems to the Gulf of Mexico.

Choctawhatchee Bay serves as a vital estuarine ecosystem, where freshwater from rivers and creeks mixes with the saltwater from the Gulf of Mexico, serving as a vital estuarine ecosystem. This unique brackish water environment supports a rich diversity of flora and fauna, including

various fish species, shellfish, migratory birds, and wetland vegetation, contributing to the overall biodiversity of the region. It also plays a significant role in the local economy of Walton County as it supports commercial and recreational fishing industries, providing livelihoods for local fishermen and contributing to the seafood industry, while also offering a range of recreational opportunities for residents and visitors alike, such as boating, kayaking, paddle boarding, and sailing. **Error! Reference source not found.** shows the bathymetry offshore.

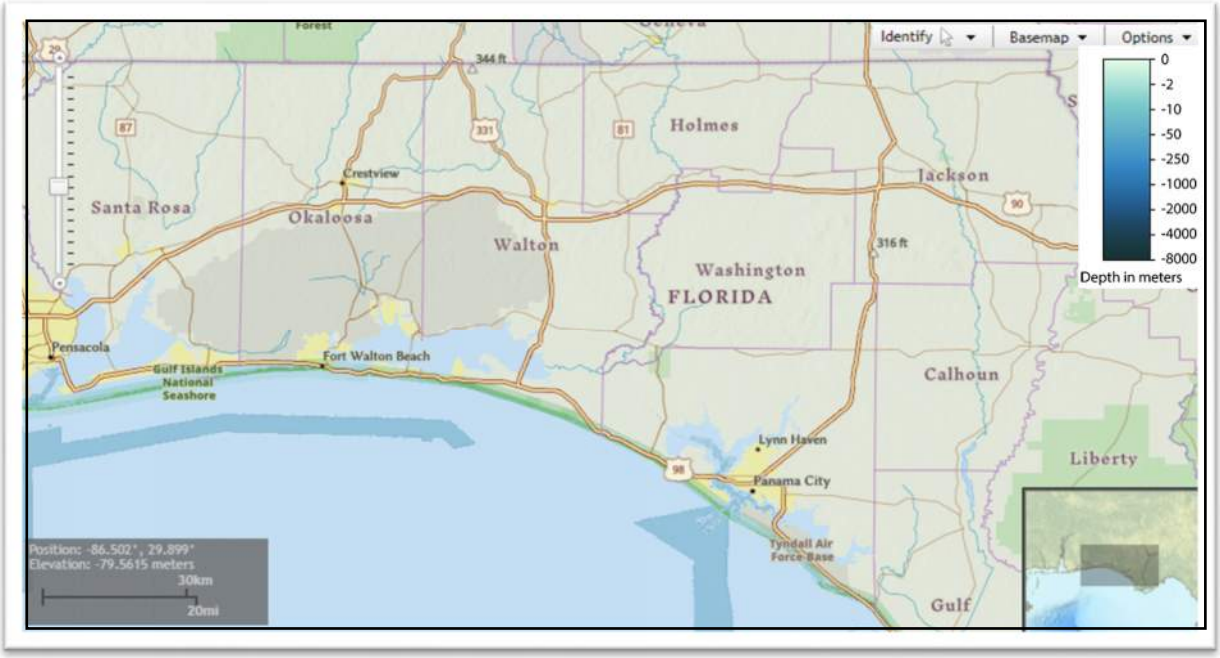

Figure 6. Bathymetry map of the shore of Walton County and surrounding counties of Florida Panhandle. Source: ncei.noaa.gov/maps/bathymetry/

Numerous tributaries exist throughout both the freshwater and estuarine portions of the watershed and can influence the overall hydrology of the area depending on rainfall and regional hydrological conditions. **Error! Reference source not found.** shows the location of all four surface water stations along with ground water stations (wells) and the drainage network of Walton County.

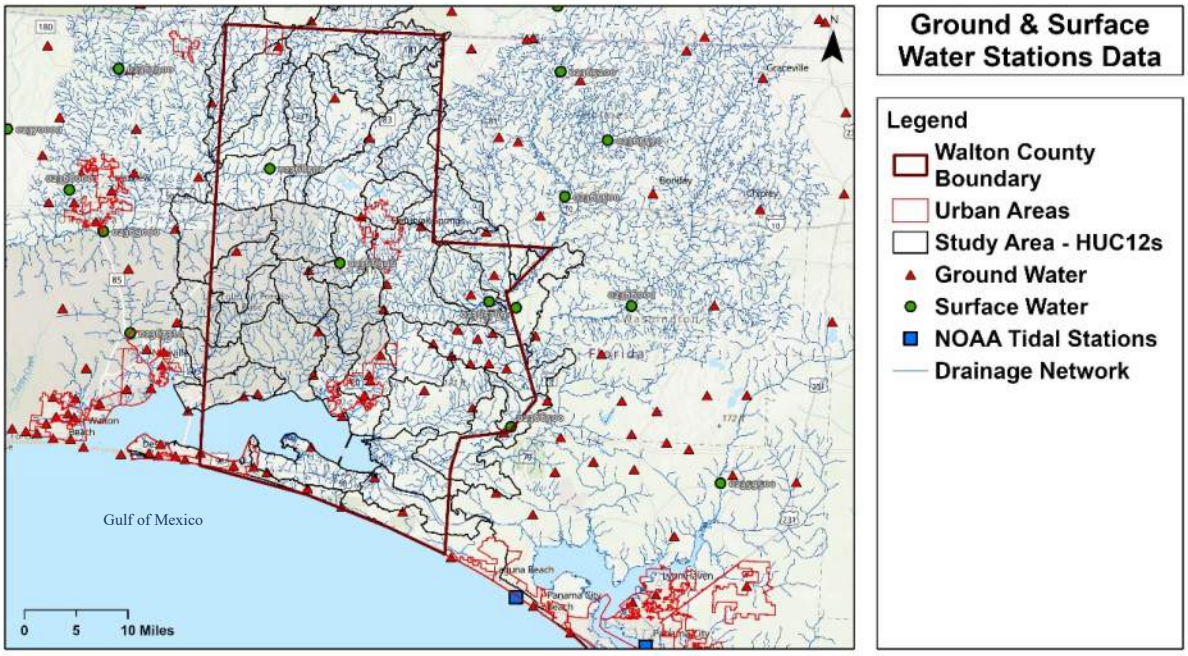

Figure 7. Ground & Surface Water Stations with drainage network for Walton County, processed by FAU. Source: ncei.noaa.gov/maps/bathymetry/

1.1.3 Hydrologic Boundaries

The geographic area of the subject sub-watershed should be clearly defined to ensure that implementing the WMP will address all the major sources and causes of impairments and threats. Although there is no rigorous definition or delineation of this concept, one way to identify the geographic extent of the watershed master planning effort is to consult the United States Geological Survey (USGS) map of hydrologic units. A hydrologic unit is part of a watershed mapping classification system showing various areas of land that contribute surface water runoff to designated outlet points, such as lakes or stream segments. USGS designates drainage areas as sub-watersheds (including smaller drainages) numbered with 12-digit hydrologic unit codes (HUCs), nested within watersheds (10-digit HUCs). These are combined into larger drainage areas called subbasins (8 digits), basins (6 digits), and subregions (4 digits), which make up the large regional drainage basins (2 digits).

Region>>Subregion>>Basin>>Sub-basin>>Watershed>>Sub-watershed

The major water bodies in the HUC 031402030903 sub-watershed include:

- Choctawhatchee River
- Holmes Creek

- Seven Runs
- Mill Branch
- McKinnon Branch
- Palmetto Branch
- Grape Head Branch
- Sugar Mill Branch

Given that stream flow data are critical for estimating flooding, **Error! Reference source not found.** shows the historical streamflow during June 2022 to July 2023 for USGS 02365769. However, as there are only four surface water station within Walton County, it was necessary to use the nearest station to the sub-watershed 031402030903, which is USGS 02365769 Bruce Creek at SH 81 NR Redbay, FL.

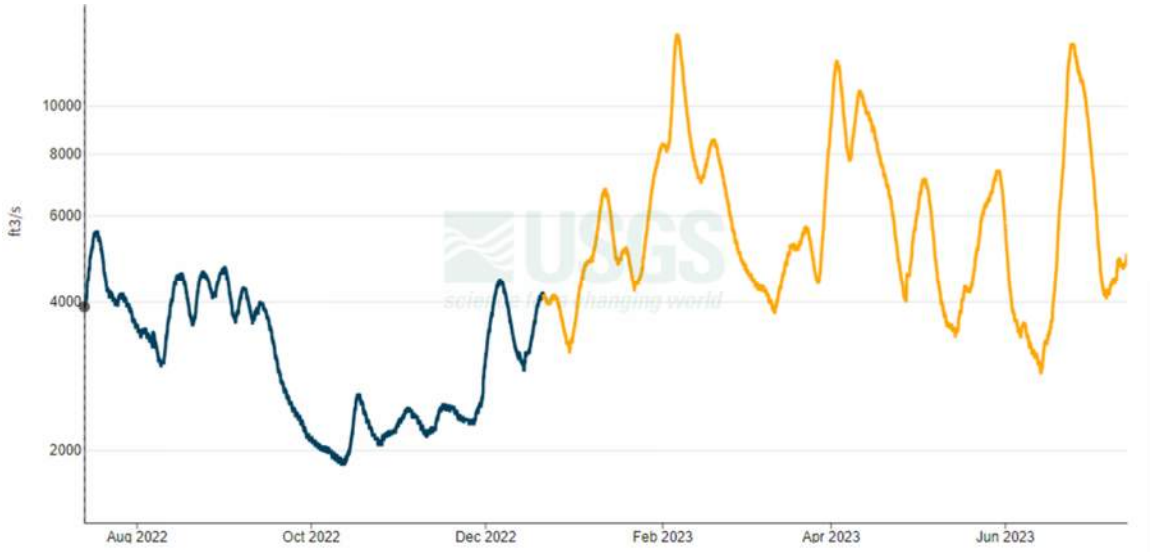

Figure 8. Average streamflow for Bruce Creek at SH 81 NR Redbay, FL (USGS 02365769 Surface-Water, June 2022 to July 2023).
Source: USGS Water Data Services (waterdata.usgs.gov/monitoring-location/02365769/#parameterCode=00065&period=P7D).

1.2 Groundwater

In this region of Florida, there is a direct interaction between groundwater and surface water. In addition to low land elevations and topographic relief, the groundwater and surface water are controlled by the canals, rivers, and tides. Since there is a limited number of groundwater monitoring stations, the strong relationship between groundwater and surface water was leveraged to develop a 99th- percentile surface of the water table elevation for mapping purposes. To establish

a common date for modeling, the recorded groundwater table elevations were sorted in ascending order to determine the 98th - 100th percentile date of occurrence in Excel®, following the procedure detailed in Romah (2011). This procedure was automated for this effort using a python code to process the groundwater data more efficiently. Outliers and anomalous groundwater levels in the database are initially identified (e.g. catastrophic storm events) and replaced by region-specific mean values based on observations available from the nearest well. Missing date-specific data are estimated using simple temporal interpolation based on observations available in time. If a station (or monitoring well) data contains large amounts of missing data, it is not used in the generation of the groundwater surface.

In Walton County, the average annual rainfall is abundant, reaching 65 inches at DeFuniak Springs. This rainfall predominantly infiltrates the sand-and-gravel aquifer and eventually seeps into streams or the underlying artesian Floridan aquifer. The county's two major aquifers are the sand-and-gravel aquifer and the Floridan aquifer. While the sand-and-gravel aquifer provides water for rural domestic use and plays a crucial role in water storage and streamflow maintenance, it also serves as a recharge source for the Floridan aquifer. Water from the sand-and-gravel aquifer contains varying levels of dissolved solids, pH, and iron content. The Floridan aquifer, being the primary water supply source, underlies the entire county and yields around 500 to 1,000 gallons per minute from wells, except along the Gulf Coast where the permeability is lower. Recharged by leakage from the sand-and-gravel aquifer, the Floridan aquifer's movement is predominantly southward away from the potentiometric high in northwestern Walton County. It discharges through springs, seeps along the Choctawhatchee River, and by wells. In southern Alabama, the Floridan aquifer is directly recharged by rainfall when it is exposed or close to the land surface. (Bureau of Ecology, 1974).

Once a common time period is determined across the majority of shallow groundwater wells, canal data can be gathered for that common date (and two days prior, in the event the canals were deliberately lowered). Data was obtained from the NWFWMD and processed by FAU at cwr3.fau.edu. Between stations, an ArcGIS tool permits a line to be drawn to replicate the canals and establish points in a gradient between stations. The same is true for the ocean, but it is a constant head boundary. The canals form boundary conditions for the screening tool on the edges of the basin and affect localized groundwater. The tide issue is resolved by using the common date for high tide.

Error! Reference source not found. shows the drainage network of HUC 031402030903 and points out the location of the ground water stations in the surroundings. A groundwater-surface layer for the HUC 031402030903 sub-watershed was created using several datasets including water level data from USGS and NWFWMD and groundwater elevation contour maps. The datasets were used to generate a raster surface of the groundwater elevation (**Error! Reference source not found.**).

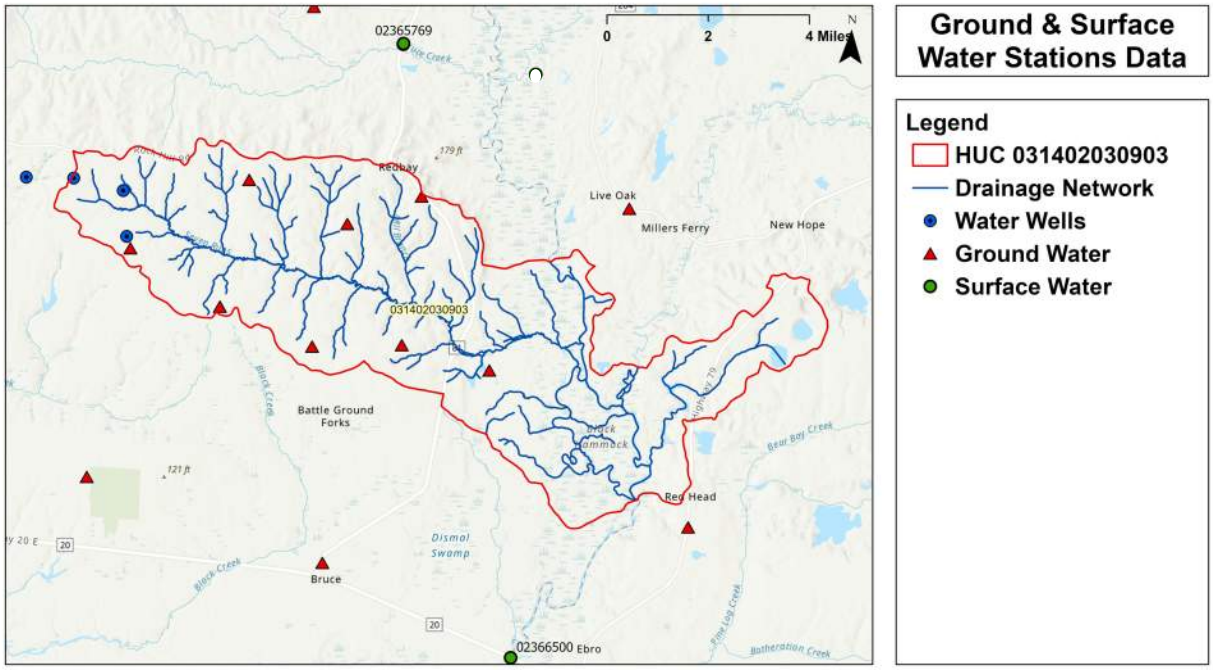

Figure 9. Ground and Surface Water Stations in the HUC 031402030903 sub-watershed, processed by FAU.

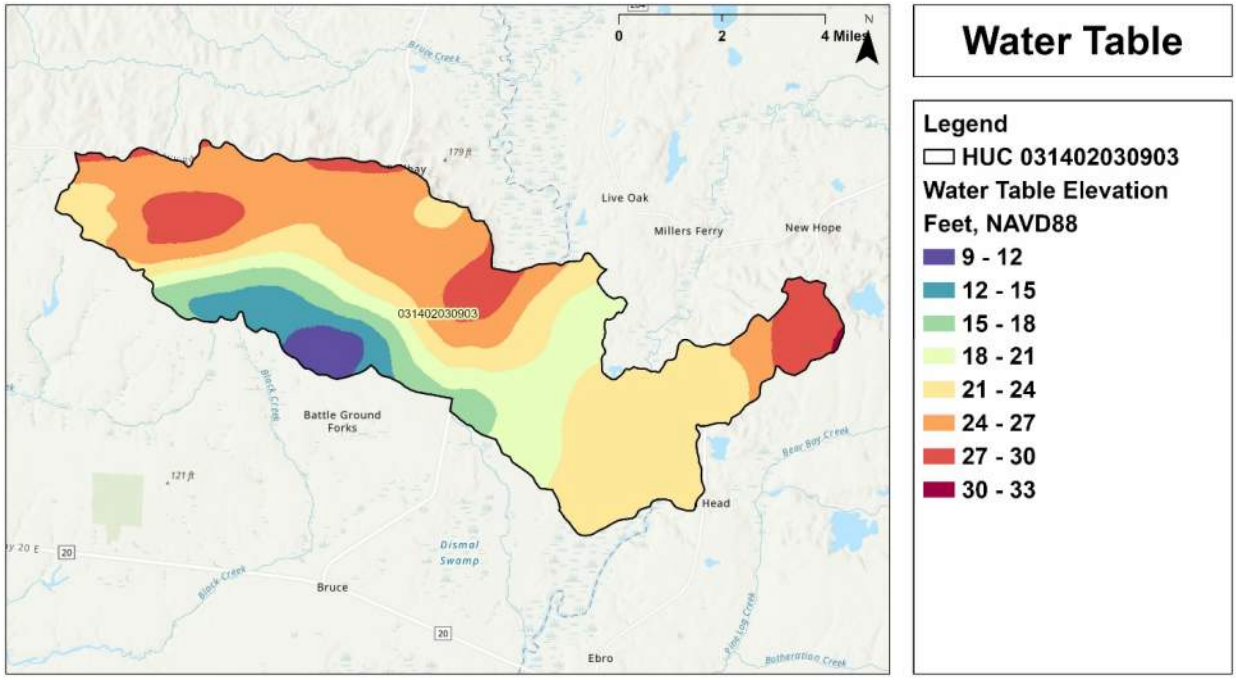

Figure 10. Elevation of the top of the surface groundwater layer for the HUC 031402030903 sub-watershed, created by multiple linear regression analysis – elevation NAVD88, processed by FAU.

1.3 Surface Water/Tides

Historically, surface water and tides have been an important factor in determining how much freshwater is delivered, how fast this water enters wetlands and estuaries, and the quality of that water. Evapotranspiration and rainfall do not coincide in the study area, which makes water supply planning difficult. **Error! Reference source not found.** shows the average precipitation over Walton County for every month of the year between 2011 and 2023- each rectangle is a month and each column is a year. The 12-month total precipitation decreased 7.5 inches from May 1900 to April 2023. From May 1900 to April 2023, the average 12-month total precipitation was 60.5 inches for the entire county.

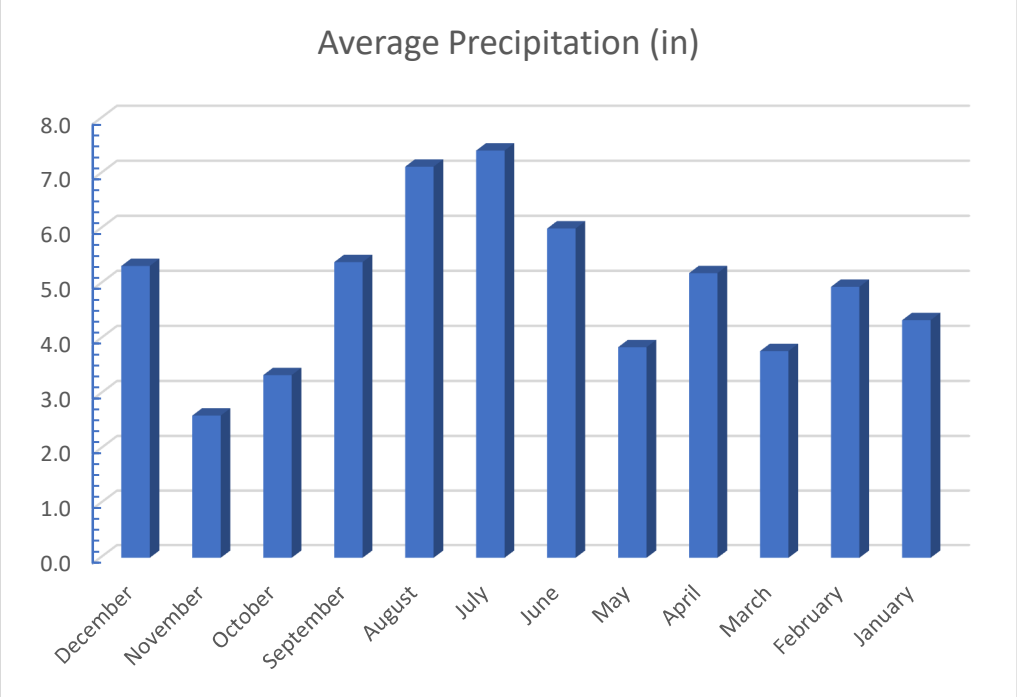

Figure 11. Monthly precipitation in Walton County, FL (2011-2023).
(Data Source: Florida Weather Data, available at https://data.usatoday.com/weather-data/walton-county/12131/1975-04-01/Table/)

While the topography (Section 1.1) and native soil (Section 1.4)create an environment that is highly permeable and capable of infiltrating significant percolation into the soil, changes in land use and land cover have resulted in water falling on impervious areas, where the water collects in pools or runs off rapidly, in direct contrast to the natural condition. This runoff flowing over impermeable regions can lead to larger scale flooding.

Tidal data can be gathered from NOAA tidal gages and other gages monitored by local governments. The location of tide gages is important to ensure they accurately depict tides, as

opposed to inland waters. To set a boundary for the coastal areas, the high tide on the common date from 12/03/2018 to 12/10/2018 was selected. **Error! Reference source not found.** shows the two closest tide stations to Walton County. Since there is no NOAA tide station in Walton County, the Panama City Beach station (8729210) was used.

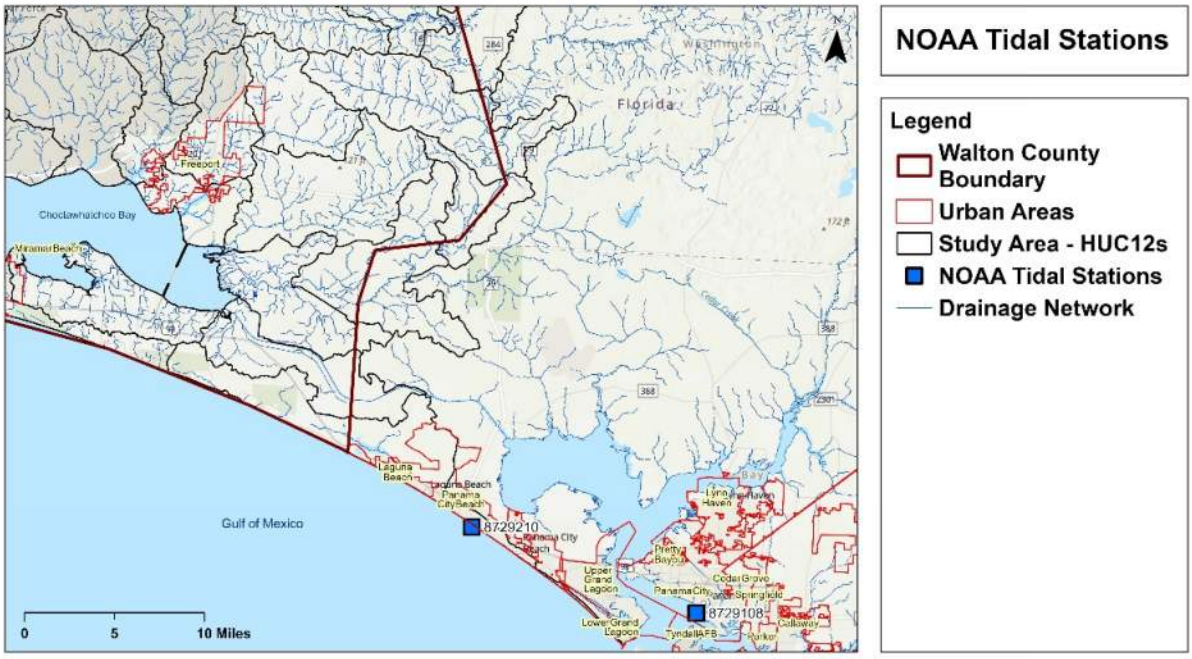

Figure 12. Locations of Florida tidal stations maintained by NOAA near to Walton County, processed by FAU.

1.4 Soils

Soil can store water if there is adequate distance between the topographic surface and the groundwater, and the soil types are capable of absorbing the water. Soil storage capacity is the volume of soil pores in the unsaturated zone that is available to store infiltrated stormwater (Gregory et al., 1998). Throughout Florida, it is common to have large volume storm events that fill the voids in the unsaturated zone as shown in **Error! Reference source not found.**.

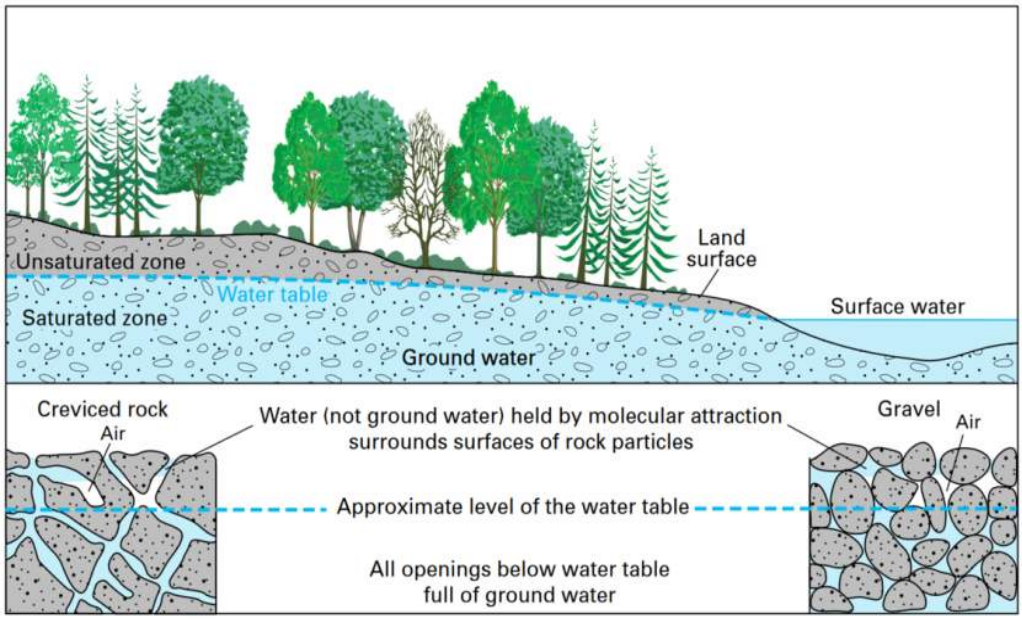

Figure 13. Zones where underground water exists.
Source: USGS, 2020.

The unsaturated zone is the portion of the subsurface above the water table that contains soil/rock and air and water in its pores as shown in **Error! Reference source not found.**. This zone affects the rate at which the aquifer is recharged by controlling water movement from the surface of the land downward towards the aquifer. During rain events, the soil voids fill up quickly resulting in the water table rising to the surface, and the surplus rainfall becomes runoff.

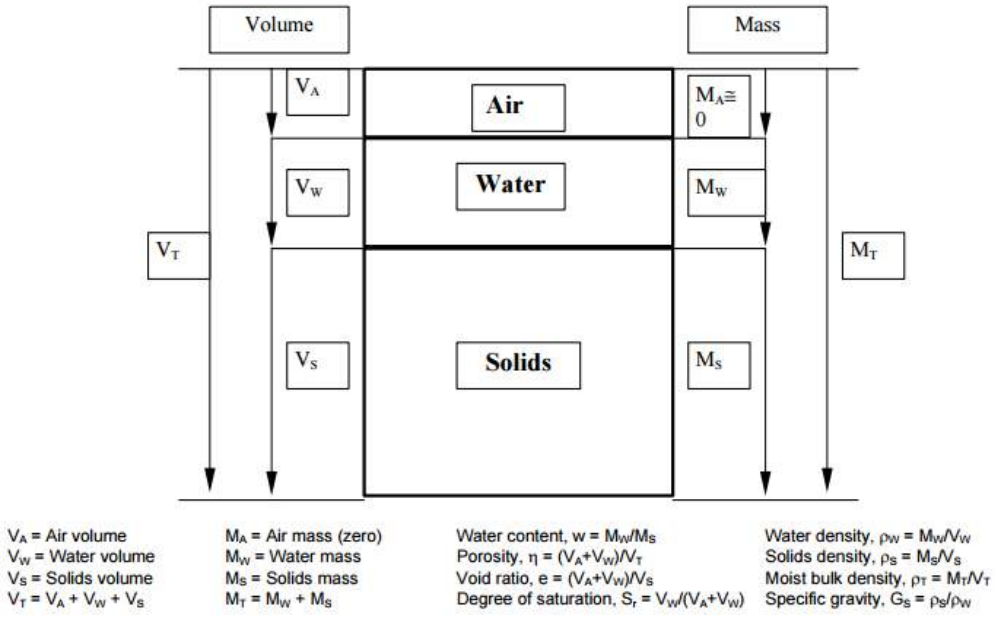

Figure 14. Saturated zone soil phase diagram and definitions.
Source: Gregory et al., 1998.

Soil data is available from the United States Department of Agriculture (USDA) or other agencies in the form of maps that can be incorporated as a GIS layer. The Gridded SSURGO (gSSURGO) dataset from USDA is chosen. This dataset is similar to the standard product from USDA Natural Resources Conservation Service (NRCS) Soil Survey Geographic (SSURGO) database, but is in the Environmental Systems Research Institute, Inc. (ESRI®) file geodatabase format. A file geodatabase allows for statewide or even Conterminous United States (CONUS) tiling of data. The gSSURGO dataset contains all of the original soil attribute tables in SSURGO. All spatial data are stored within the geodatabase instead of externally as separate shape files. Both SSURGO and gSSURGO are considered products of the National Cooperative Soil Survey (NCSS). **Error! Reference source not found.** shows the unsaturated zone found by the difference between the groundwater elevation layer and surface topography.

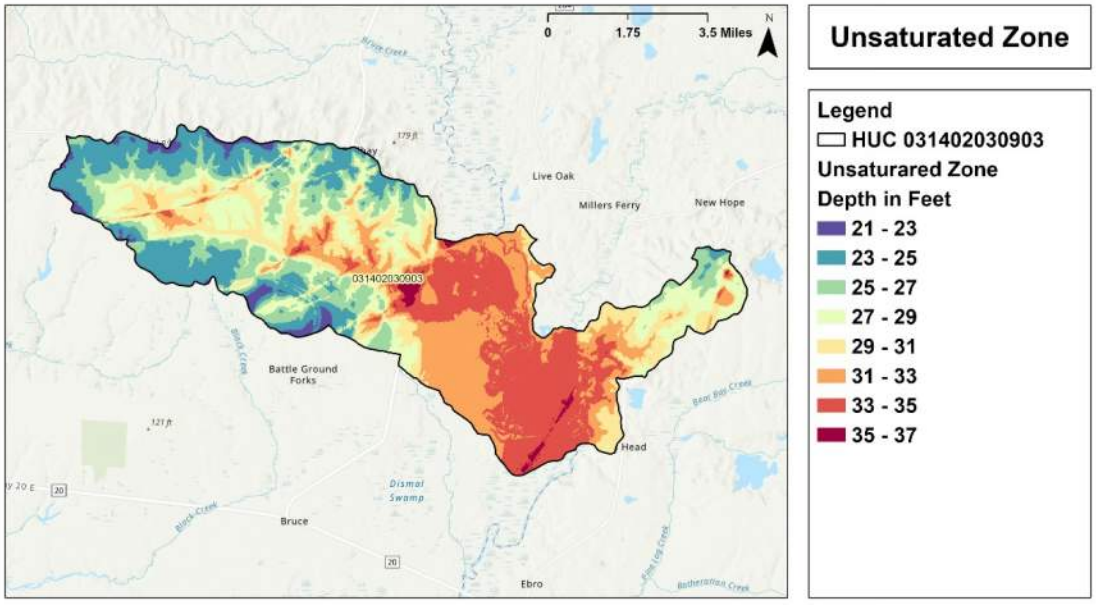

Figure 15. Unsaturated zone map for HUC 031402030903, processed by FAU.

The available water storage from USDA derived for the soil layer (0-150 cm or 0-5 ft) statewide is shown in **Error! Reference source not found.**, which covers most of Florida with a spatial resolution of 10 m. The unit is in cm. As a result of applying this layer to the study area (**Error! Reference source not found.**), the estimated soil storage capacity can be illustrated. A significant portion of the basin demonstrates a moderately favorable soil storage capacity, falling within the range of 23 to 35 feet of remaining capacity.

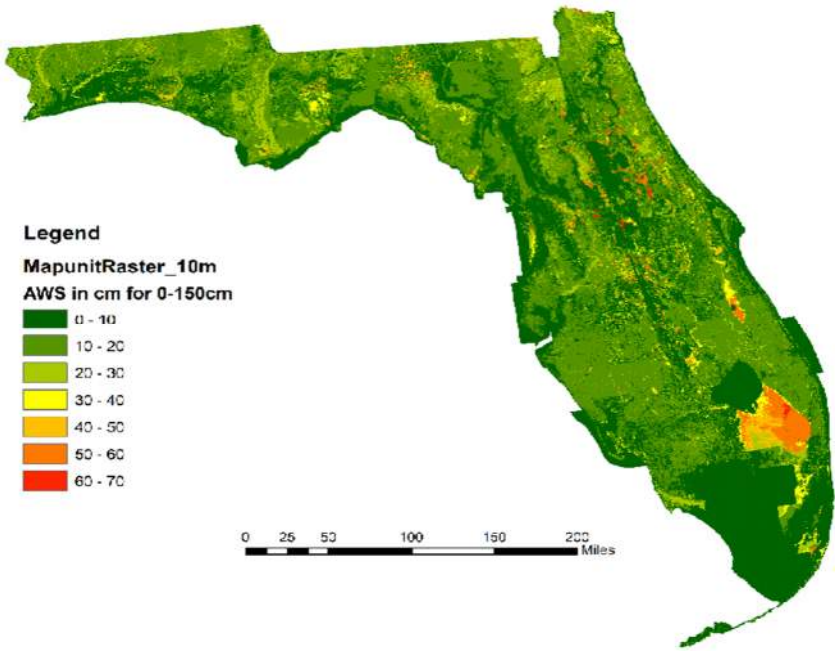

Figure 16. Available water storage derived from the gSSURGO soil database for all of Florida, processed by FAU.

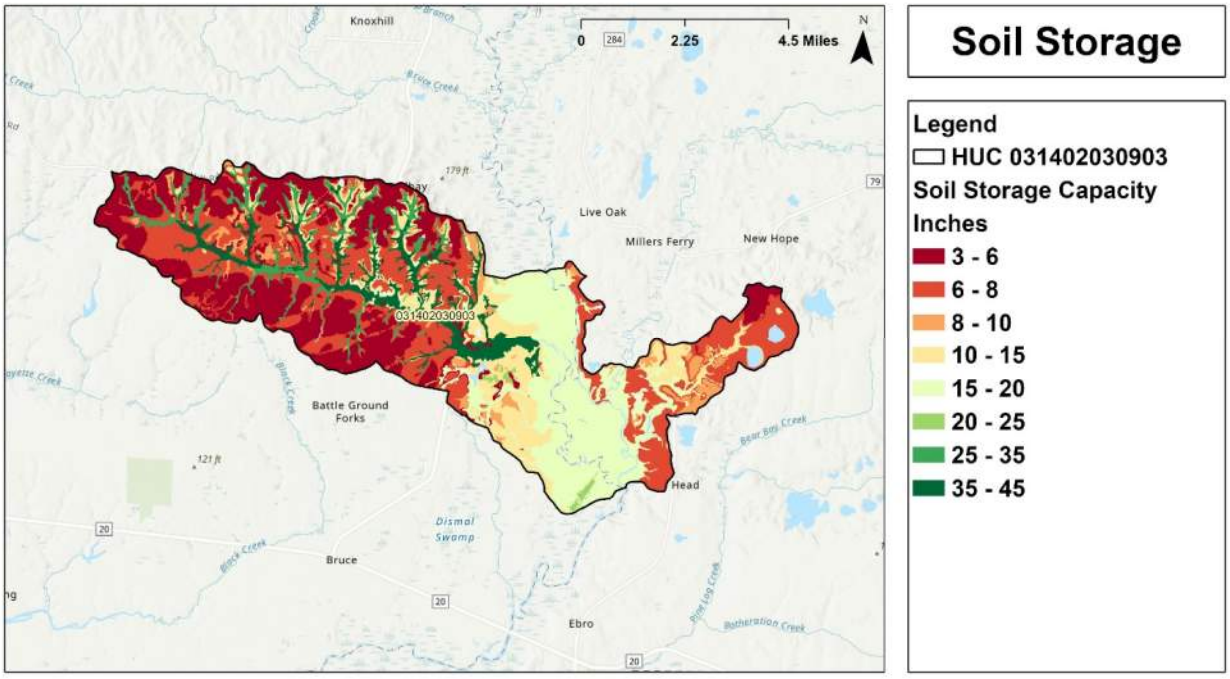

Figure 17. Water storage capacity of soil for the HUC 031402030903, processed by FAU.

Lastly, **Error! Reference source not found.** shows the water holding capacity for the basin, which refers to the capacity of a particular soil texture to retain water against the force of gravity.

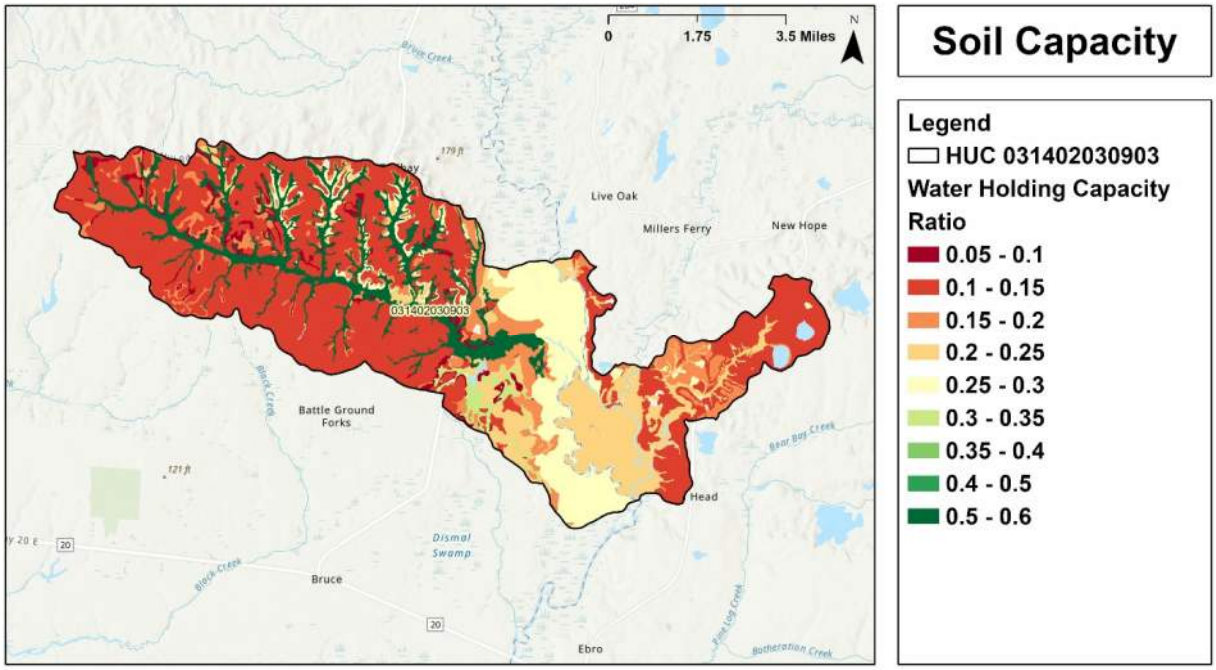

Figure 18: Water Holding Capacity (ratio) for the HUC 031402030903, processed by FAU.

1.5 Land Cover

The USGS produces the NLCD of nationwide data on land cover at a 30-m resolution with a 16-class legend based on a modified Anderson Level II classification system. NLCD is coordinated through the 10-member Multi-Resolution Land Characteristics Consortium (MRLC) to provide digital land cover information nationwide. For the conterminous United States, NLCD 2016 contains 28 different land cover products characterizing land cover and land cover change across 7 epochs from 2001-2016, urban imperviousness and urban imperviousness change across 4 epochs from 2001-2016, tree canopy and tree canopy change across 2 epochs from 2011-2016 and western U.S. shrub and grassland areas for 2016 (**Error! Reference source not found.**).

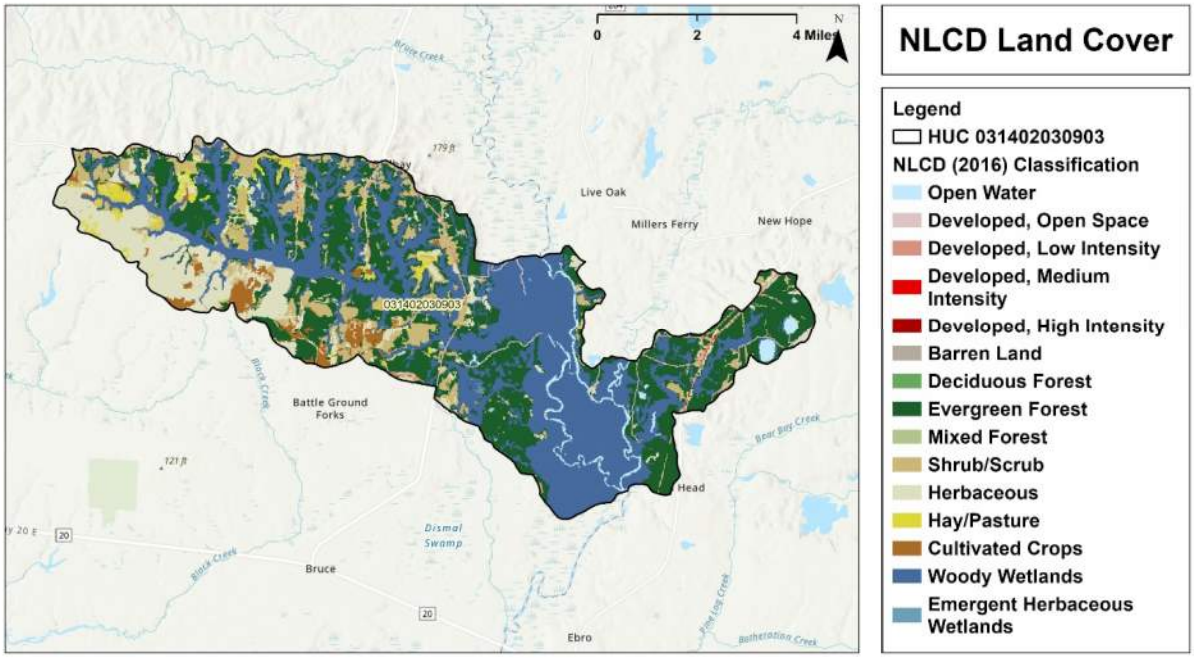

Figure 19. Land use in the HUC 031402030903 (from the NLCD 2016 database), processed by FAU.

The dataset is derived from the Florida Land Use Cover Classification System (FLUCCS), which is digitized by photo-interpretation on county-based aerial photography with varying resolution in the range of 4 in - 2 ft pixel. The NLCD 2016 has a 30-meter resolution derived from Landsat imagery. Hence, the NLCD maps appear much coarser and pixelated compared to the 2023 Florida Geographic Data Library (FGDL) (https://fgdl.org/fgdlmap/) maps. . A view of the latter is provided in **Error! Reference source not found.**. The future land use maps need to be used for the final land cover, as adjusted for future stormwater improvements set by regulatory standards.

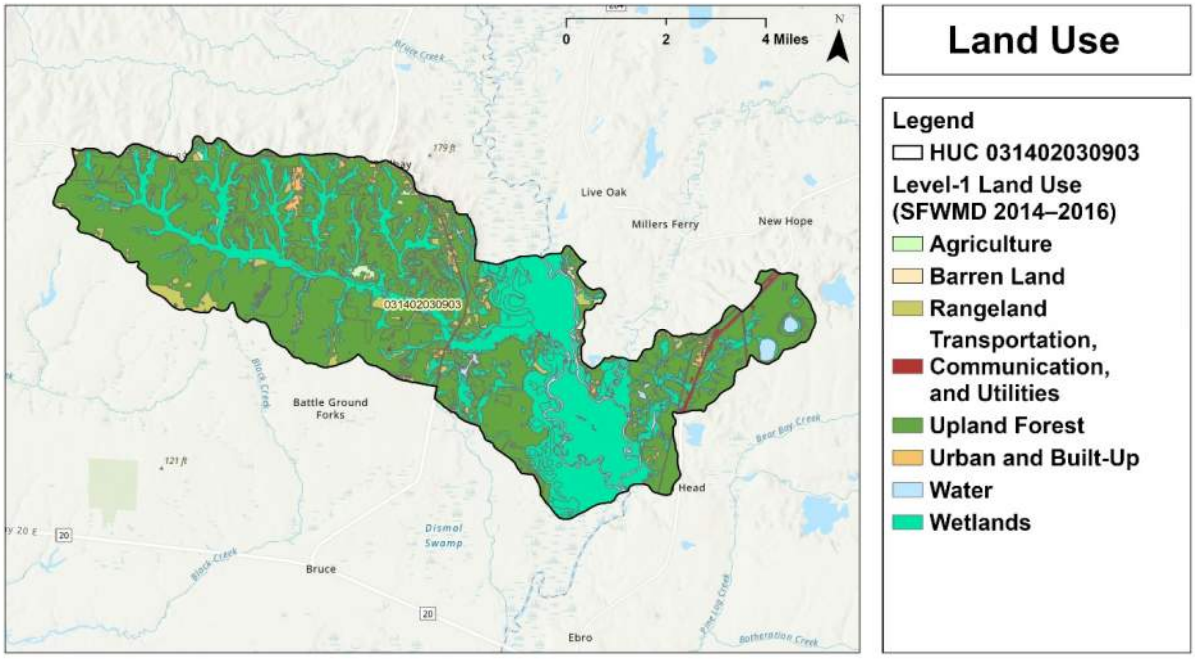

Figure 20. Land use in the HUC 031402030903 (from 2023 Florida Geographic Data Library (FGDL) database))

In the HUC 031402030502 sub-watershed, the predominant land cover is upland forest, accounting for 54.48% of the area. Wetlands comes in second at 27.72%, followed by water at 6.88%, and Transportation, Communication, and Utilities at 6.73%. Developed land constitutes a minor portion, with only 1.17% categorized as urban and built-up, as shown in **Error! Reference source not found.**. **Error! Reference source not found.** shows the roughness of the surface.

Table 3. Land use for HUC 031402030903 sub-watershed

Level 1 Land Use Land Cover Type	**Area (Acres)**	**Percentage of Total**
Agriculture	123.04	0.27%
Barren Land	13.25	0.03%
Rangeland	1247.11	2.72%
Transportation, Communication, and Utilities	3086.35	6.73%
Upland Forest	24975.29	54.48%
Urban and Built-Up	538.00	1.17%
Water	3152.29	6.88%
Wetlands	12705.31	27.72%
Grand Total:	**45840.65**	**100.00%**

Source Data: 2023 Florida Geographic Data Library (FGDL) database))

Table 4. Roughness and CN Values for Each Land Use Code.

DOR Code	Use	Impervious %	Roughness
0	Vacant	0	0.4
1	Single Family	29	0.25
2	Mobile homes	21	0.05
4	Condos	60	0.05
7	Vacant –to be developed	0	0.4
8	Multifamily	60	0.05
TH 101	Townhomes	91	0.025
94	Road Right-of-Ways	50	0.08
	Open water	100	n/a
All others	Commercial, etc.	50	0.07

1.6 Precipitation

Rainfall used in the screening tool is based on the SFWMD 3-day 25-year storm, but can be modified for any rainfall event using the accumulated rainfall table obtained from NOAA Atlas 14 Point Precipitation Frequency Estimates (https://hdsc.nws.noaa.gov/hdsc/pfds/pfds_map_cont.html). **Error! Reference source not found.** shows the 3-day 25-year rainfall map based on the NOAA Atlas 14 dataset for the whole state. **Error! Reference source not found.** to **Error! Reference source not found.** rainfall 1-day 100-year, 1-day 10-year, and 1-day 5-year storm event scenarios, in inches.

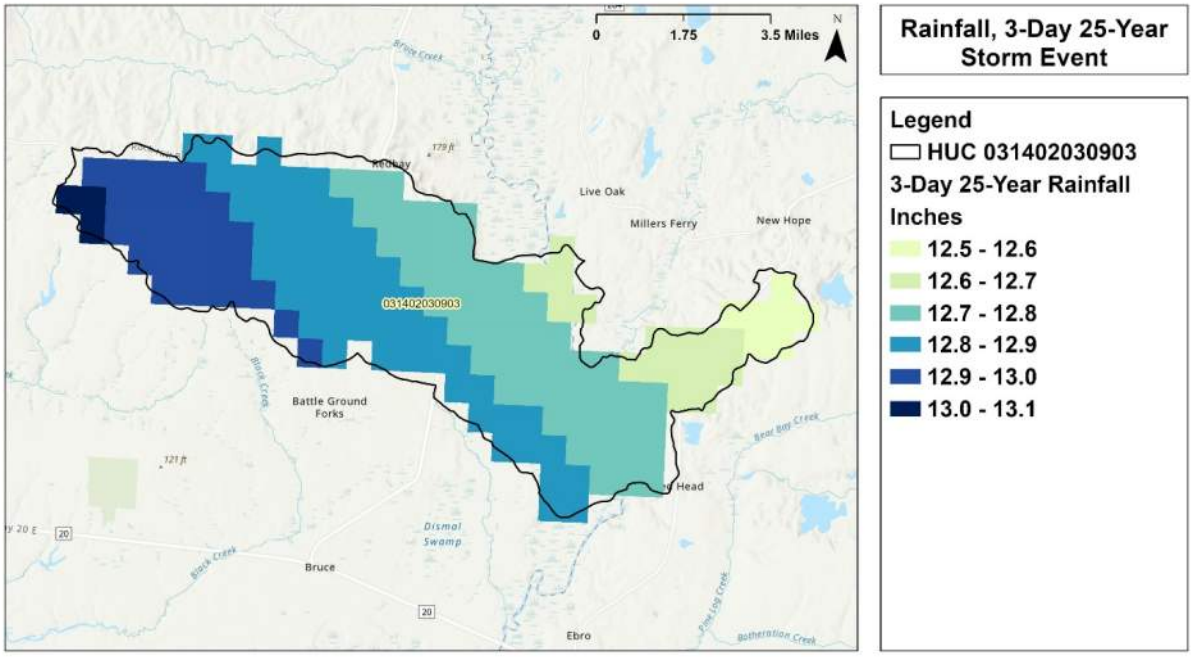

Figure 21. Rainfall distribution map across HUC 031402030903 sub-watershed, for 3-day 25-year storm event, processed by FAU.

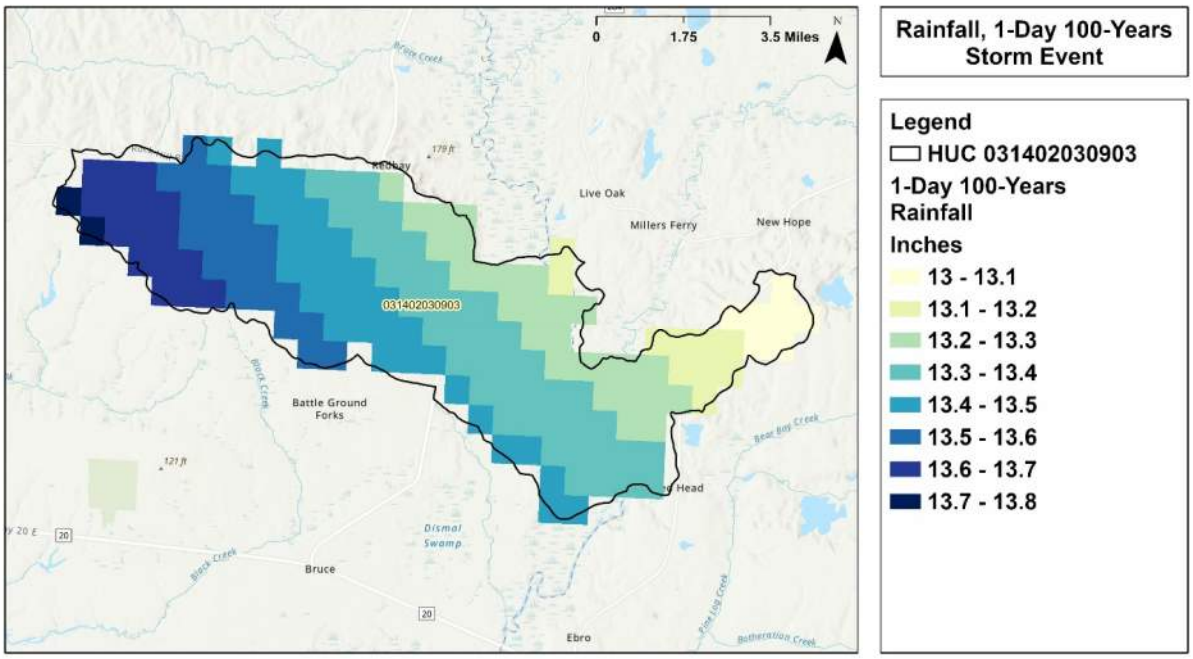

Figure 22. Rainfall distribution map across HUC 031402030903 sub-watershed, for 1-day 100-year storm event, processed by FAU.

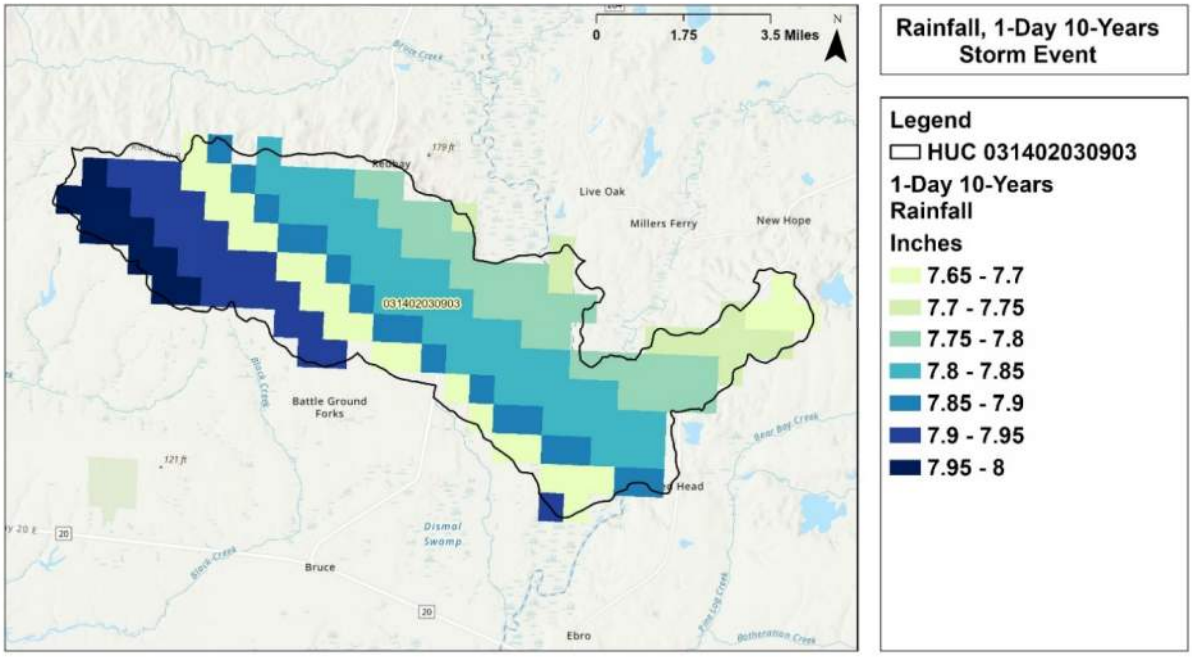

Figure 23. Rainfall distribution map across HUC 031402030903 sub-watershed, for 1-day 10-year storm event, processed by FAU.

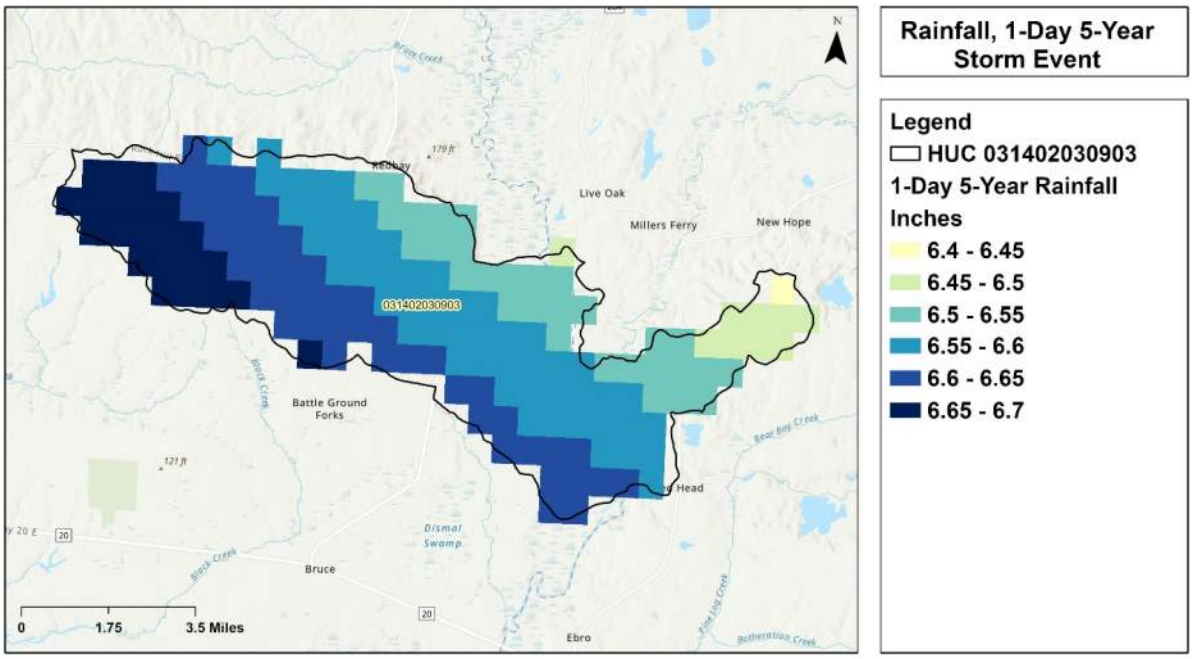

Figure 24. Rainfall distribution map across HUC 031402030903 sub-watershed, for 1-day 5-year storm event, processed by FAU.

1.7 Open Space

Open space is defined as areas that are exempted from development. Generally, this means one or more of the following qualifiers exist:

1. Land that is valuable for recreation, forestry, fishing, or conservation of wildlife or natural resources
2. Land that is a prime natural feature of the state's landscape, such as a shoreline or ridgeline
3. Land that is habitat for native plant or animal species listed as threatened, endangered, or of special concern
4. Land that is a relatively undisturbed example of an uncommon native ecological community
5. Land that is important for enhancing and conserving the water quality of lakes, rivers, and coastal water
6. Land that is valuable for preserving local agricultural heritage
7. Proximity to urban areas or areas with open space deficiencies and underserved populations
8. Vulnerability of land to development
9. Stewardship needs and management constraints
10. Preservation of forest land and water bodies that naturally absorb significant amounts of carbon dioxide

Permanent protection of sensitive areas can provide critical water quality protection and can be achieved through partnerships with landowners, municipalities, land trusts and state agencies. There is limited land in the study area that has been protected via acquisition by federal, state or local agencies, has conservation easements or is designated as wetlands or areas of critical concern. Agricultural land and other land cover will come from the land cover map (in Section 1.5). Added to this will be the water bodies discussed in Section 1.9, which serve a related condition to open space.

1.8 Impervious Areas

Impervious areas do not permit the infiltration of rainfall to groundwater, and because the water cannot infiltrate, it runs off faster. Faster runoff means that flows to water bodies and storm sewers occur faster and with higher peaks. The result is a disruption of the natural and potentially the planned hydrology. Impervious areas include pavement, buildings, and other areas that reduce runoff capacity. In other words, developed areas have much higher imperviousness than open spaces that are natural or agricultural.

The NLCD provides nationwide data on land cover and land cover change at a 30-m resolution with a 16-class legend based on a modified Anderson Level II classification system. Systematically aligned over time, the database offers the ability to understand both current and historical land cover and land cover change to enable assessment of trends. Using the NLCD 2016 dataset, a layer was created by using only three categories out of the 13 to identify impervious areas such as primary roads in urban areas, secondary roads in urban areas, and tertiary roads in urban areas. The new layer was then converted to match the 3-meter spatial resolution from the DEM and the standard State Plane Coordinate system. **Error! Reference source not found.** shows the impervious areas derived from the NLCD 2016 as updated by the future land use map.

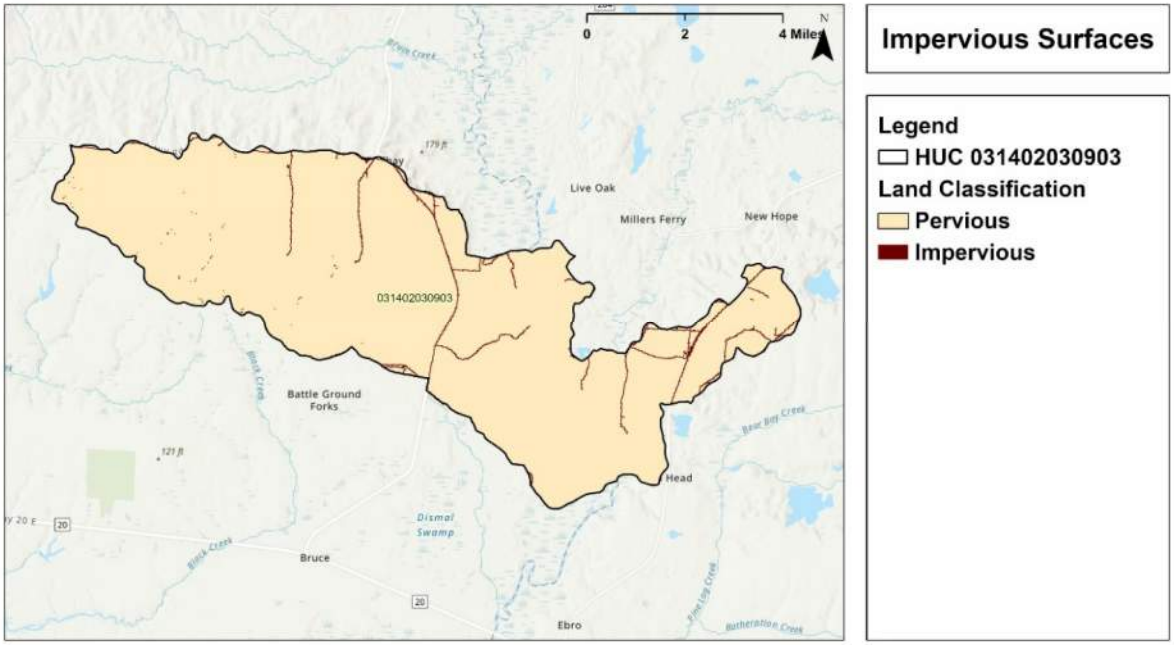

Figure 25. Impervious area map for the HUC 031402030903 sub-watershed, processed by FAU.

1.9 Water bodies

Water bodies were defined in the statewide land use land cover dataset to set soil water holding capacity to zero in model simulations (**Error! Reference source not found.**). Note that tiny water bodies may be missing from the maps. Soils were discussed previously in Section 1.4.

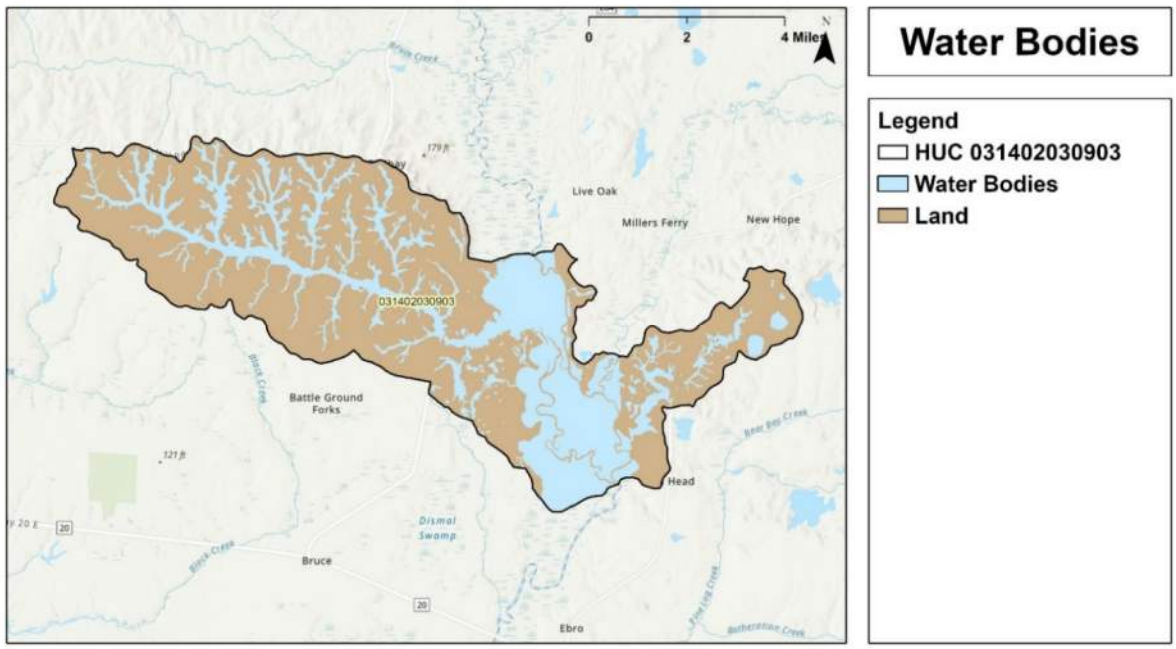

Figure 26. Water bodies map for the HUC 031402030903 sub-watershed, processed by FAU.

1.10 Natural Resources

Understanding the study area's natural resources is critical to identifying potential sources of water quality degradation and areas to designate for conservation, protection, and restoration. One possible goal of watershed master planning is to protect terrestrial wildlife, aquatic habitat, and buffer zones. USGS maintains important sources of information on physical and geographical features as well as soil and mineral resources, surface and ground water resources, topographic maps, and water quality monitoring data. The USDA's Natural Resources Inventory (NRI) (www.nrcs.usda.gov/technical/NRI) is a survey of information on natural resources on non-federal land in the United States that captures data on land cover and land use, soil erosion, prime farmland soils, wetlands, habitat diversity, erosion, conservation practices, and related items. Since 2001, the NRI has been updated continually with annual releases of NRI data from all 50 states. The information provided can be used for addressing agricultural and environmental issues down to the county or cataloging unit level. Therefore, this data can be used to determine erosion and site-specific soil characteristics for certain land uses such as croplands, pasturelands, forestlands, etc., but the data is typically provided as inventories, not GIS layers.

1.11 Demographics

Demographics data is important for determining several key indicators for watershed master planning such as the ability to pay for improvements, social justice issues, land acquisition costs, property/land use, and communication strategies. The US Census has databases at the census tract level. Based on the census data for the study area, **Error! Reference source not found.** outlines population and racial composition demographics.

Table 5. Demographics and Housing Characteristics of Cities and Towns in Walton County.

Demographic Parameter	**Miramar Beach**	**Freeport**	**DeFuniak Springs, City**	**Paxton**	**Rosemary Beach**	**Santa Rosa Beach***	**Walton County**
Type	CDP**	City	City - County Seat	Town	Unincorporated community		County
Area in square miles	7.02	18.94	13.95	4.01	17,021	68,722	1,038.29
Population (Census 2020)	8,002	5,861	5,919	556	2,878	20,567	75,305
Total Households	4,334	2,206	2,509	316	1,318	8,275	30,182
Median Household Income	$75,347	$75,637	$53,984	$41.750	$127,148	$94,648	$68,111
Median Age	56.3 years	41.4 years	37.1 years	50.6 years	52.4 years	43.20 years	45.0 years

Two or More Races	674	185	299	38			2.7%
Hispanic or Latino (Regardless of Race)	434	156	127	66	105	1,988	7.1%

(Source: US Census Bureau 2020, and Zip-codes.com)

*It includes the communities of Point Washington to the East and a 15-mile stretch of the Emerald Coast from the east side of Miramar Beach to the west side of Seagrove Beach and the beach communities along 30A, including Grayton Beach and Seaside.

** Census Designated Place

1.12 Stormwater Infrastructure Inventory

Local community stormwater systems consist of drainage ditches, storm sewers, retention ponds and other facilities constructed to store runoff or carry it to a receiving stream, lake, ocean, or other waterbody. Other man-made features include yards and swales that collect runoff and direct it to the sewers and ditches. When most of these systems were built, they were typically designed to handle the amount of water expected during a 10-year storm. Larger storms overload them, and the resulting backed-up sewers and overloaded ditches produce shallow flooding. Another urban drainage problem occurs in the areas protected by levees. Being in floodplains, they are flat and do not drain naturally, especially when a levee blocks the flow to the river. To drain these areas, channels have been built and pumps installed to mechanically move the water past the levee. Often, these man-made systems do not have the capacity to handle heavy rains or intense storms.

Another challenge with stormwater infrastructure is related to recordkeeping. It is not uncommon for stormwater data to be incomplete in most jurisdictions and completely lacking in others. Quality of data differs from jurisdiction to jurisdiction; some are in GIS formats, while others are paper maps or as-builts that represent the infrastructure at a macroscale level. The condition of the assets may be lacking, and the maintenance history may not be available either. Stormwater assets may have been installed with no records, especially in rural areas, farm fields, and private property.

Walton County passed Ordinance No. 2008-06 that prohibits unauthorized discharges into storm drains or ditch systems. In addition, the Public Works Division is currently running a continuous public awareness campaign aimed at encouraging the adoption of best management practices (BMPs) for managing stormwater runoff. This initiative targets both the business community and the residents of Walton County.

To address the issue of flooding, Walton County has implemented several measures along the years, such as:

- Drainage Systems: The county has invested in the development and maintenance of drainage systems, including ditches, canals, and retention ponds, to manage stormwater runoff and reduce flood risk.
- Floodplain Management: Walton County has adopted floodplain management regulations and participates in the National Flood Insurance Program (NFIP) to encourage responsible development in flood-prone areas.
- Elevation Standards: New construction projects within flood zones are required to adhere to specific elevation standards to minimize potential flood damage.

- Emergency Response: The county has established emergency response plans to assist residents during flood events, including evacuation procedures and the provision of emergency shelters.

Key stormwater assets for the HUC and Walton County are indicated in **Error! Reference source not found.** and **Error! Reference source not found.**, respectively. Stormwater structures and management processes in the county consist of stormwater outfall, water wells, weir, pollutant control boxes, inlets catch basins, pipes culverts, ditch conveyance swales, structures, pipes and open conveyance.

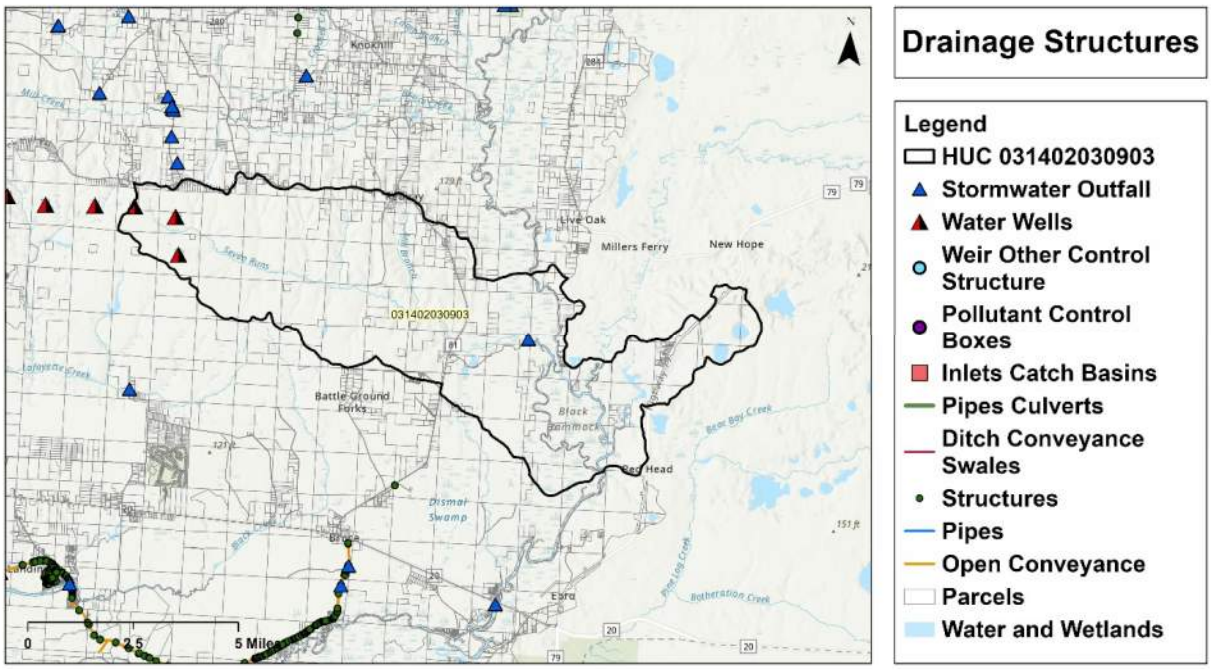

Figure 27. Stormwater Infrastructure for the HUC 031402030903. Processed by FAU.

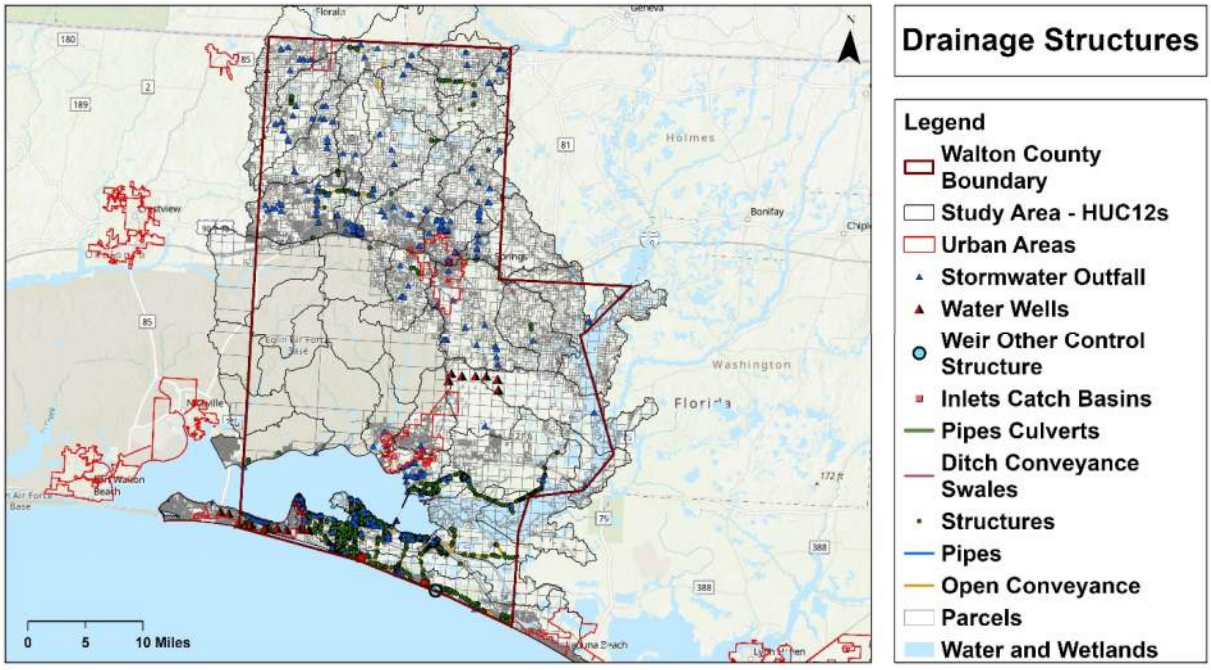

Figure 28.Stormwater Infrastructure for Walton County. Processed by FAU.

Although nature-based infrastructure might be installed, it is not certain. The stormwater system must maintain compliance with the stormwater regulations, which requires record-keeping, policy development, inspections and maintenance. The goals of such stormwater management may include:

- Best landscape practice;
- Control car washing contribution to pollution;
- Enforce the Stormwater Pollution Prevention Plan (SWPPP) by site evaluation, assessment, erosion and sediment controls, preventive maintenance, certification and inspection reporting for construction sites and city planning;
- Implement a hazardous material elimination system;
- Eliminate illicit dumping;
- Proactive and reactive catch basin inspections and maintenance;
- Street sweeping to control debris;
- Maintain swales to help prevent stormwater pollution flooding.

1.13 Data Gaps

FAU has developed comprehensive databases to address the information needed for the vulnerability assessment. These are included in **Error! Reference source not found.**. The data

can be used to model the impacts of flood routing during the storm of interest. As a result, the modeling pieces (discussed in Chapter 2) will include the following:

- Flood response model results (Cascade 2001)
- Flood risk/hazard mapping
- Vulnerability assessments to identify areas of concern for future repetitive losses

There is only one data gap for the area – existing stormwater infrastructure records are incomplete. However, for the purposes of this plan, this data gap does not limit the findings as there are two scales: 1) the sub-watershed level and 2) community hotspots. A neighborhood level vulnerability assessment will require the local infrastructure inventory.

Table 6. List of datasets collected by FAU as of List of datasets collected by FAU for the project (12/20/2020)

2.0 ASSESSMENT OF VULNERABLE AREAS

Defining flood risk due to compounding hydrographic influences is the central concern of this WMP. Modeling and assessment of vulnerability focused on the combination of a high-water table, heavy rains, and impervious conditions that can lead to localized nuisance flooding events. Through a previous survey with local officials, the number of days of continuous nuisance flooding that the public will tolerate before that flooding is considered destructive is about 4 days (E Science 2014).

For a large study area, small parts may actually be at risk. The point is to identify where further study might be needed. A screening tool accomplishes this goal applied to the sub-watershed scale to designate areas that are susceptible to periodic flooding events. Utilizing the information collected and analyzed in Chapters 1, analysis of flood vulnerability can be performed.

2.1 Historical and Existing Challenges

Walton County has faced various historical and existing challenges as well as natural hazards over the years. Some of these include:

- Hurricane and Tropical Storms: being situated along the Gulf Coast, Walton County is vulnerable to hurricanes and tropical storms, which can lead to damage to the built and natural environment, as well as poses risks to human and wild life.
- Coastal Erosion: The county's coastline is subject to erosion due to natural processes and human activities. Erosion can lead to the loss of beaches and threaten coastal structures and properties.
- Flooding: heavy rainfall, storm surges from hurricanes, and other factors can cause localized flooding, particularly in low-lying areas. Flood events can disrupt daily life, damage property, and impact transportation.
- Water Quality and Quantity: as in many coastal areas, managing water quality and maintaining an adequate water supply are ongoing challenges. Pollution from stormwater runoff and other sources can affect water quality, and groundwater resources need to be carefully managed to sustain the growing population.
- Wetland Loss: The county's wetlands face the threat of degradation and loss due to urban development and other human activities. Protecting these essential ecosystems is vital for maintaining biodiversity and mitigating flood risks.
- Urbanization and Development: Balancing the demand for development and growth with the preservation of natural habitats and resources is a persistent challenge. Unplanned

urbanization can lead to habitat destruction, increased runoff, and exacerbate flooding risks.

- Land Use and Zoning: Proper land use planning and zoning are essential to address issues related to population growth, infrastructure development, and natural hazard mitigation. Ensuring responsible development practices can help minimize risks.
- Invasive Species: Like many regions, Walton County faces the threat of invasive plant and animal species. These invasive species can disrupt local ecosystems, negatively impacting native flora and fauna.
- Sea-Level Rise: With rising sea levels due to climate change, coastal communities like Walton County's coastal areas are at greater risk of inundation and storm surges during extreme weather events.

The fast growth of the population and urban development in the coastal areas of the county exacerbates effort to protect open space for land percolation of water. While regulations are in place to reduce the influx of stormwater, the challenges will continue with development.

2.1.1 Existing Management Efforts in the Watershed

The county is under Northwest Florida Management District (NWFMWD) jurisdiction, which covers the Florida Panhandle region. The NWFMWD is responsible for managing and protecting water resources in its designated regions, which includes issues related to water supply, water quality, flood control, and natural resource conservation. Local governments have local stormwater utility infrastructure and planning/policy tools to reduce future flood potential. Most of the major projects to date have been focused on addressing twater quality issues and flooding due to extreme rainfall.

2.1.2 Critical Target Areas Identification

By modeling the HUC 031402030903 sub-watershed flood response to a series of rainfall events and sea levels (plus king tides), and further classifying flood risk as the probability of inundation, it is possible to identify critical target areas. These areas are particularly vulnerable to flooding and are subject to further study through a scaled-down modeling approach. The screening tool is first applied at the greater watershed level to provide an initial risk assessment focused on the hydrologic response to a rainfall event given the unique characteristics and features of the sub-watershed or study area. The process is discussed later in Section 2.2 with results presented in Section 2.4.

2.1.3 Potential Preservation Areas

Walton County boasts several areas with high biodiversity value. These areas include the unique coastal dune lakes, which support diverse ecosystems and contribute to water quality along the coast. Wetlands are crucial habitats that provide refuge for a variety of plant and animal species while acting as natural water filters. State parks like Topsail Hill Preserve and Grayton Beach State Park are valuable conservation areas with diverse coastal ecosystems. Additionally, preserving the Choctawhatchee River Basin is essential for the biodiversity of the region.

2.2 Vulnerability Maps

2.2.1 Screening Tool

The screening tool utilizes topographic data from various sources (Section 1.1), water table elevations (Section 1.2) and surface water gauges (Section 1.3) downloaded from the NWFWMD website, tidal information for coastal areas obtained from the NOAA Current & Tides website (Section 1.3), soil maps obtained from the USDA (Section 1.4), and another key dataset as described previously in Chapter 1. The design storms are discussed in Section 1.6. The reason this is critical is that to do any modeling (as required by the CRS program), a screening tool should be used to identify regions with a high risk of inundation based on multiple collected datasets and hydrological models. **Error! Reference source not found.** shows how the GIS layers interface in the tool and how they are combined for spatial analysis.

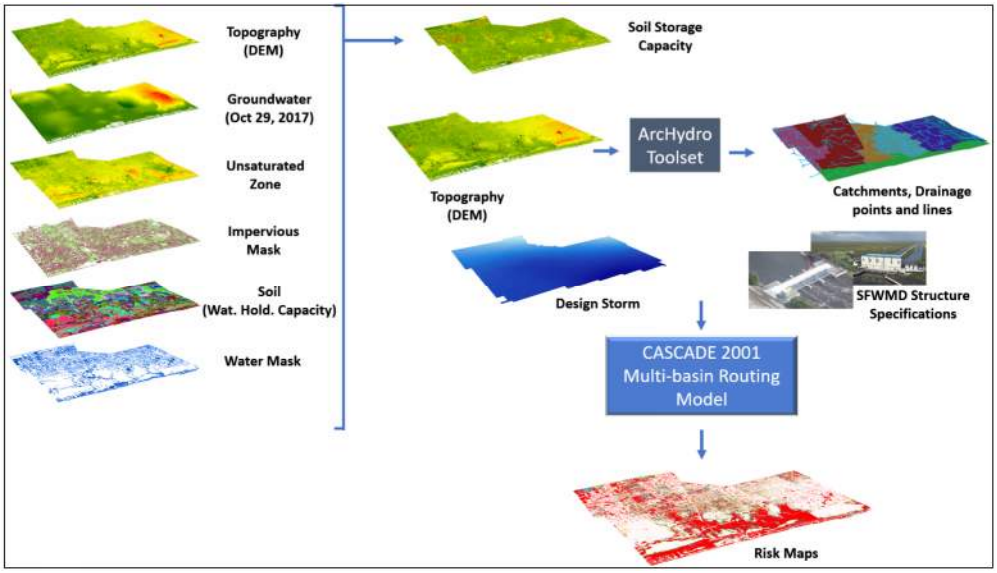

Figure 29. Screening tool methodology for creating flood risk maps.

The model chosen for this screening tool is Cascade 2001, which is a multi-basin hydrologic/hydraulic routing model developed by the SFWMD. The model permits the investigator to run different storm events to determine flooding scenarios. The boundaries are critical for basin studies and must be chosen carefully. The following data layers collected in the prior section are processed to develop the input files for Cascade 2001:

- Topography
- Soils
- Development intensity
- Groundwater elevations
- Surface water/Outlet locations

The software creates a glass box where water rises to a certain level and then decreases. Running the simulation requires defining the basin (HUC or sub-HUC) and input of the following data:

- Area
- Portion of area above a given elevation
- Initial groundwater stage
- Longest travel time for the runoff to reach the most distance point of discharge
- Ground storage as estimated from the USDA gridded National Soil Survey Geographic Database (gNATSGO)

  Ground storage ≈ (Water holding capacity) × (Surface elevation – GW elevation)
  = 2 × (AWS for a soil layer of 0-150 cm) / 150cm × (Surface elevation – GW elevation)

- Available water storage (AWS) for a soil layer of 0-150 cm
- Average amount of precipitation that can be stored in the soil layer

The output from the model is an elevation surface that can be used to develop a flood map for the study area (**Error! Reference source not found.**), which shows the spatial distribution of probabilities of flooding during the modeled 1-day 100-year storm event.

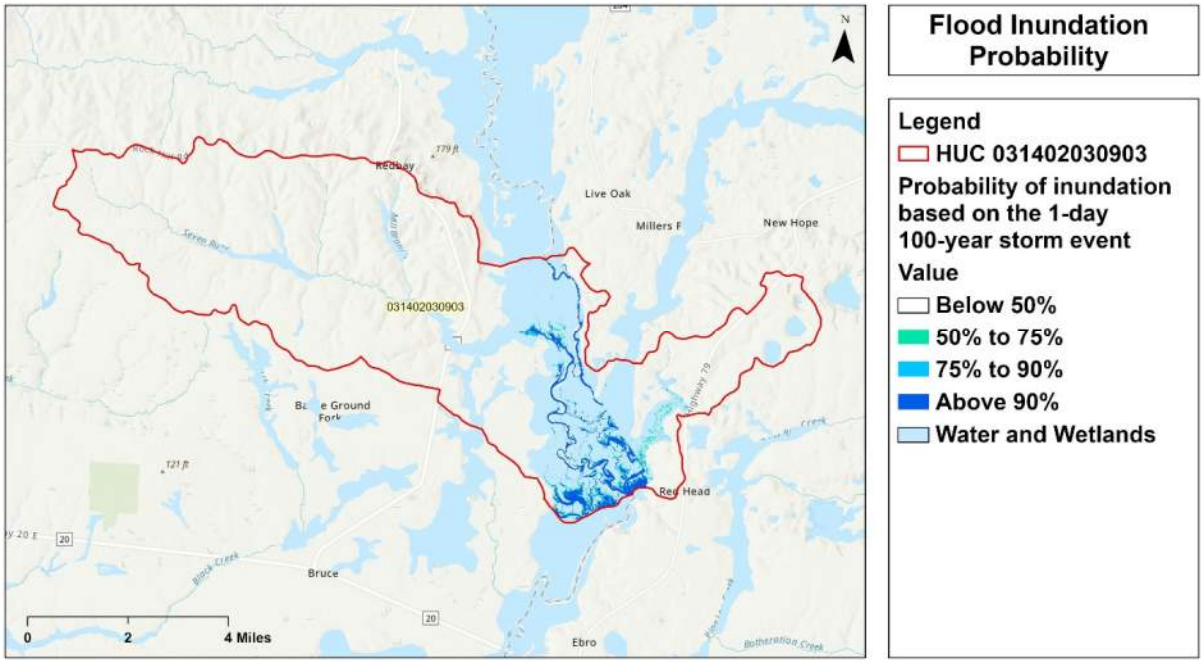

Figure 30. Probability of flood risk map during the modeled 1-day 100-year storm event for the HUC 031402030903, processed by FAU.

2.2.2 Identification of Vulnerable Areas

Given these assumptions and the Cascade 2001 outputs, the goal of this methodology is to produce a spatially-temporally quantified understanding of nuisance-destructive flood potential in the study area given observed values. Risk is a function of compounding geo-hydrological features, namely, surface water, groundwater, topography, build-out, and time of year. A GIS-based algorithm and spatial interpolation generated layers of the greatest observable hydrographic surfaces. These outputs were then compared with high resolution topographic LiDAR data to develop digital elevation models that reflect the observed risk landscape. These models can then be combined into Cascade 2001 to produce vector and volume information, in combination with soils, vegetation and impervious surfaces, allowing the observed model outputs to be extrapolated into a more predictive context.

To evaluate flood vulnerability at this scale, the analysis starts with a binary flooding surface (0 = below 50% chance of flooding; 1 = above 50% flooding) based on output from the screening tool for a specified design storm. Next, attributes of that raster based on "VALUE = 1" query are extracted using *Extract by Attributes* tool. Then the *Batch Project* tool was used to map critical facilities data to the common coordinate system (NAD83 UTM Zone 17N), unit = meters. Then a field was added using *Add Field* for [PriorityTier] = assigned Tier #1-4 value from the DOR codes

and [Area_sqmeter]. The critical facilities layers were then merged into a single layer to calculate the polygon geometry for [Area_sqmeter] using the *Merge* tool. Next, *Zonal Statistics as Table* is used to calculate the SUM of flooded values ("VALUE = 1") within each critical parcel. Output table has fields for SUM (i.e., total # of flooded pixels per critical parcel) and AREA in map units of square meters (since each pixel in the flooding surface has a cell size of 3-meters by 3-meters, each area is equal to the SUM value multiplied by 9 m^2). Using the *Join Field* tool, the SUM and AREA fields are joined to the merged critical facilities layer based on a key attribute, first renaming these fields for clarity (e.g., AREA_FLOODED_3d25y). Once all field data is included, the next step involves using *Export Table* to export the dataset as a CSV file. Note that non-flooded parcels have zero flooded area, so they receive a <Null> value from the zonal statistics tool. To replace null values with zeros, we use *Calculate Field* in the attribute table along with the following Python expression (replacing the respective field name): "0 if !AREA_FLOODED_3d25y! is None else !AREA_FLOODED_3d25y!". Next, the CSV file is saved as an Excel Workbook (.xlsx). The Range is converted to an Excel Table, and the columns are rearranged in the desired order. Finally, the "percent-flooded" columns are calculated as follows:

- PCT_FLOODED_3d25y = ([@[AREA_FLOODED_3d25y]]/[@[TotalArea_sqmeter]])*100
- PCT_FLOODED_1d100y = ([@[AREA_FLOODED_1d100y]]/[@[TotalArea_sqmeter]])*100

After this calculation, the table is sorted to show the higher priority tiers and higher percent-flooded values first. To reduce the number of critical facilities shown in the final table, a filter was created to show only critical facilities with 10% or more flooded area in the parcel during both storm events. Records with duplicate parcel ID numbers were removed from the table. The results of this procedure are discussed in Section 2.5 of this document.

With respect to dams and levees, for purposes of the NFIP, FEMA only recognizes systems that meet, and continue to meet, minimum design, operation, and maintenance standards that are consistent with comprehensive floodplain management criteria. The Code of Federal Regulations, Title 44, Section 65.10 (44 CFR 65.10) describes the information needed for FEMA to determine if a levee system reduces the risk from the 1% annual chance flood. FEMA has accredited levees and Provisionally Accredited Levees (that have a specified timeframe to obtain the necessary data to confirm the levee's certification status). If a levee system no longer meets Section 65.10, FEMA will de-accredit the levee system and issue an effective FIRM showing the levee-impacted area as a SFHA. FEMA coordinates its programs with USACE, who may inspect, maintain, and repair levee systems. USACE has authority under Public Law 84-99 to supplement local efforts to repair flood control projects that are damaged by floods. Like FEMA, USACE provides a program to allow public sponsors or operators to address levee system maintenance deficiencies. Failure to do so within the required timeframe results in the levee system being placed in an inactive status in

the USACE Rehabilitation and Inspection Program. Levee systems in an inactive status are not eligible for rehabilitation assistance under Public Law 84-99. There are no levees/dams listed in the sub-watershed study area.

2.3 Future Challenges of Sea Level Rise and Climate Change

Global observations from satellites and long-term data collection have made it possible to document and analyze patterns in the Earth's climate. Scientific analysis of the impact of these changes has helped to improve the understanding of future flood hazard driving forces and long-term impacts on human activities and watershed master planning (http://www.research.noaa.gov/climate/t_observing.html). Examples of impacts are rising global average air and ocean temperatures, increased and earlier snow and ice melt, shorter subtropical rainy seasons, shifted seasons, sea level rise and greater variations in temperature and precipitation (IPCC, 2013; Freas et al., 2008; Marshall et al., 2004; Bloetscher et al., 2010). Marshall et al. (2004) specifically focused on the Florida peninsula to predict changes in rainfall and warmer temperatures but interspersed lower low temperatures due to the potential loss of wetlands.

Future changes in climate will add to the existing impacts, at a time when the population of the state is expected to nearly double by 2030. Additional research and high-resolution climate modeling for the Florida peninsula and local jurisdictions is needed to help guide long-term plans like WMPs. Rainfall appears to be decreasing and temperatures rising (see **Error! Reference source not found.**).

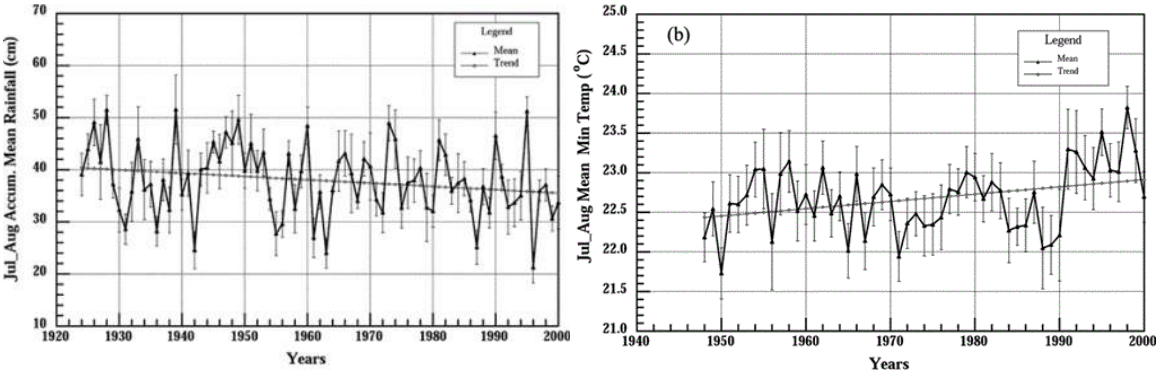

Figure 31. Change in average rainfall and change in average temp 1924 to 2000.
Note the reversed trend, which means groundwater input variability is lessened.
Source: Marshall et al., 2004.

Climate change is likely to: 1) threaten the integrity and availability of fresh water supplies and 2) increase the risk of flooding, not only in the low-lying coastal areas, but also in the interior flood plains. Other issues include a) saltwater intrusion, which may be intensified by sea level rise, b) prolonged droughts that will contribute to water supply shortages and wildfires, and c) heavier

rains during the rainy season and higher hurricane storm surge, which may increase the risk due to flooding. More frequent and damaging floods are likely to become an ever-increasing problem as sea level continues to rise because of: a) increasing groundwater table elevations and surface water gage heights, b) reduced groundwater seepage through the aquifer to the ocean, c) increasingly compromised stormwater drainage systems, and d) more frequent inundation of barrier islands and coastal areas.

NOAA and IPCC (2013) predictions suggest that by 2100, global temperatures will be on the order of 2-3°C (3-5°F) higher and sea levels will rise by up to 3 feet. Accompanying these drivers are potential changes in storm frequency and intensity, desertification, population migration, ocean acidification and coastal flooding (IPCC, 2007), exacerbated by the land cover and land use changes, which are substantially impacted by the fluxes, timing and quality of precipitation (Adrians et al., 2003; Scanlon et al., 2005; Marshall et al., 2004; Salmun and Molod, 2006), and leading to changes in the timing of peak flows and volumes (Richey and Costa-Cabral, 2006).

The results of these climatic changes are likely to: 1) threaten the integrity and availability of fresh water supplies and 2) increase the risk of flooding, not only in the low-lying coastal areas, but also in the interior flood plains. Other issues include a) saltwater intrusion, which may be intensified by sea level rise, b) prolonged droughts that will contribute to water supply shortages and wildfires, and c) heavier rains during the rainy season and higher hurricane storm surge, which may increase the risk due to flooding. More frequent and damaging floods are likely to become an ever-increasing problem as sea level continues to rise because of: a) increasing groundwater table elevations and surface water gage heights, b) reduced groundwater seepage through the aquifer to the ocean, c) increasingly An outcome of these climatic patterns is that during the past 140 years, an increase in sea levels has been observed (Bloetscher, 2012), a worrying pattern since sea level rise is a permanent phenomenon, that can be catastrophic to low lying areas in the long-term. The question is how much and how soon? Various studies (Bindoff et al., 2007; Domingues et al., 2008; Edwards, 2007; Gregory, 2008; Vermeer and Rahmstorf, 2009; Jevrejeva, Moore and Grinsted, 2010; Bloetscher, 2010, 2011; IPCC, 2007; Heimlich et al., 2009) indicate large uncertainty in projections of sea level rise by 2100. Gregory et al. (2012) note that during the last two decades, the global rate of sea level rise has been larger than the 20th-century time-mean, and Church et al. (2011) suggested that the cause was increased rates of thermal expansion, glacier mass loss, and ice discharge from icesheets. Gregory et al. (2012) suggested that there may also be increasing contributions to global sea level rise from the effects of groundwater depletion, reservoir impoundment, and loss of storage capacity in surface waters due to siltation. Measurements of Florida's east coast (Maul, 2008) show an average rate of sea level rise of 2.27 ± 0.04 mm per year from 1915 to 1992 based on tide gauge readings. Analyzing the tidal gauge readings for Florida shows that:

1. Florida average sea level rise is 2.10 ± 0.49 mm/yr

2. All but one location is within the 95% confidence limit range (the exception is Panama City where there is evidence of submergence and other land-based issues)
3. None of the Florida sea level rise rates differ statistically
4. Average global sea level rise for 1920-2000 was 2.0 mm/yr – within 95% confidence limit for Florida locations

From 1929 to 1992, over eight inches of sea, with another 6 inches added since 1992, which is already having significant impacts on coastal communities where population growth has increased the need for improved flood management strategies (Bloetscher, 2008; Parkinson, 2010; Zhang et al., 2011, 2011a; NFIP, 2011; Schmidt et al., 2011; Warner et al., 2012).

As a result, the SFRCCC (2015) adopted USACE's methodology to derive scenarios of sea level change intermediate to high rates of sea level rise for years 2030 (3" to 7") and 2060 (9" to 24") as the consensus projection to guide future planning. The path keeps increasing – now 14 inches since 1929 (**Error! Reference source not found.**) caused by thermal expansion of the ocean and melting ice caps (Jevrejeva et al., 2010; Vermeer and Rahmstorf, 2009). Sea level rise is a major concern in Florida, including Walton County, since the majority of the state's population live on the coast, involving most major commercial, residential, and economic enterprises. **Error! Reference source not found.** demonstrate the estimated sea level change for Panama City, considering the predictions of NOAA 2017. For NOAA high scenario SLR change scenario, the estimated level change is higher than 8 ft., while for the intermediate and low scenarios are about 3.9 feet and 1.7 feet respectively.

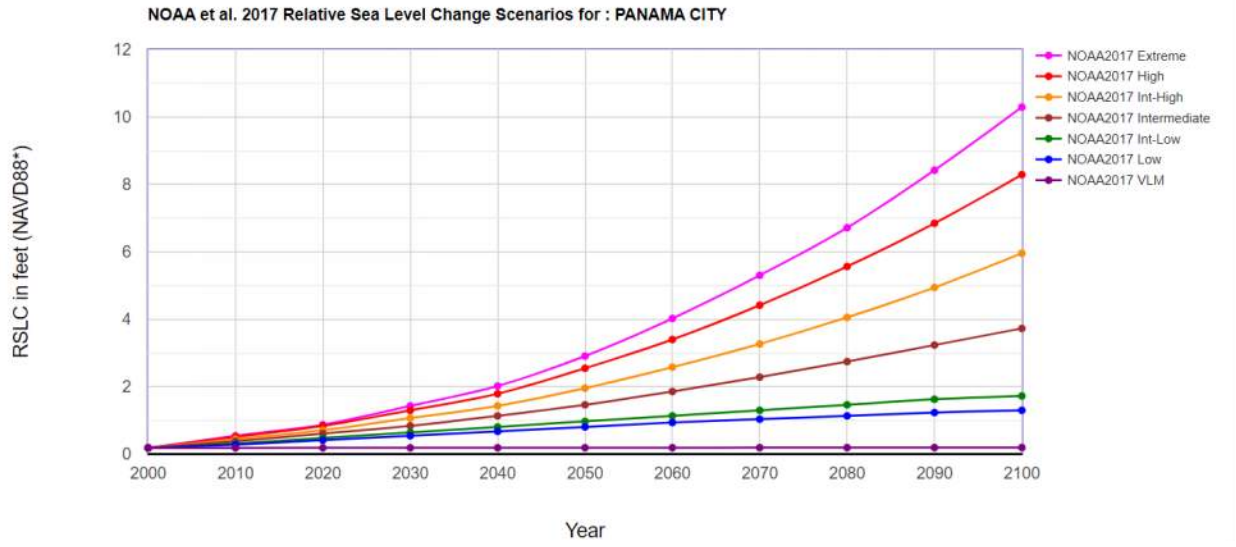

Figure 32. Relative Sea Level Change Scenarios for gauge 8729108, Panama City, FL. Source: NOAA 2017 (Source: https://cwbi-app.sec.usace.army.mil/rccslc/slcc_calc.html).

NOAA (2017) outlines five scenarios for sea level rise. The NFIP proposes the use of the intermediate high projection, which is 1.2 meters or 4 ft globally from current sea level elevations (**Error! Reference source not found.**).

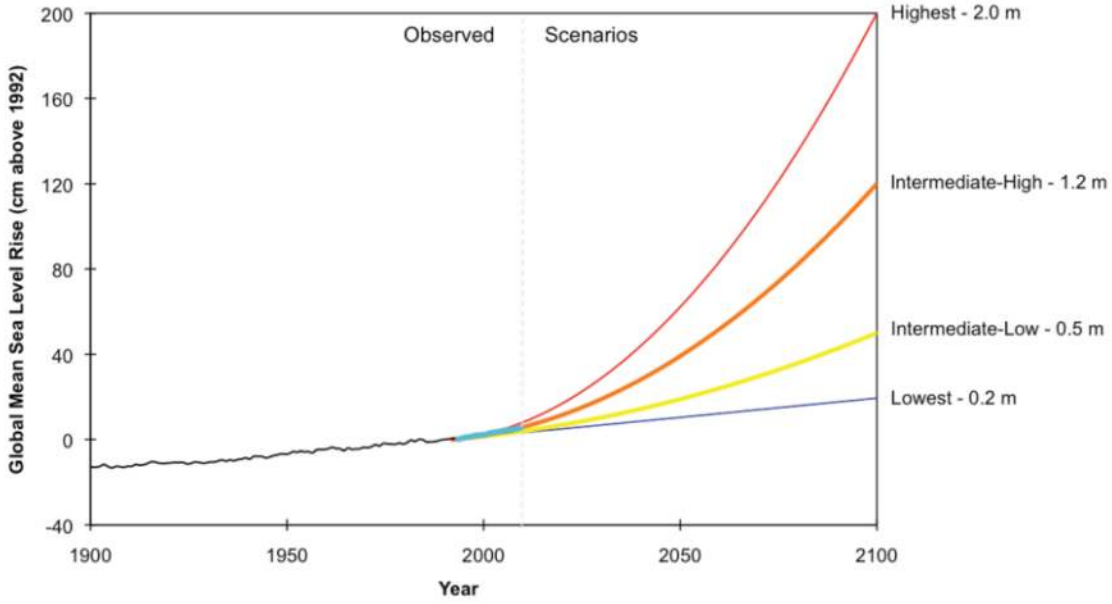

Figure 33. Graphic of global sea level rise projections from NOAA (2017). Source:https://tidesandcurrents.noaa.gov/publications/techrpt83_Global_and_Regional_SLR_Scenarios_for_the_US_final.pdf

As sea level rises, access to roads, bridges, rail, and transit could be at risk of flooding, causing the effects of sea level rise to spread indirectly throughout the entire transportation network, affecting the overall system performance. For example, the flooding of a critical road or facility access can cause a shifting of traffic flow causing congested conditions in other roadways that are not actually flooded. Since the roadway network would be unable to carry the traffic demand, the system would experience operational failure; as a result, causing travel times and delays. Moreover, the inundation of a critical access could cause transportation connectivity problems to essential infrastructure like ports or airports. Transportation infrastructure relies on the effectiveness of flood control and stormwater drainage systems for the transportation corridors. Road integrity relies on adequate drainage. The increased risk of severe flooding in Florida's low-lying terrain can adversely affect transportation infrastructure along the coastline; roads can be inundated, and roadway beds can be damaged. Sea level rise will cause increased water table levels (FDOT, 2012), as regional water tables cannot exist naturally below mean high tide (2 feet in Florida). Adding 3 feet of sea level rise on top of groundwater would compound the risk of flooding in low-lying areas. Road bases below 5 feet NVGD would become saturated under this scenario, likely causing premature base failure. As soil storage capacity is diminished due to rising groundwater elevations associated with sea level rise, the potential for more frequently flooded roadways would likely damage pavements (FDOT, 2012). Hence sea level rise must be accounted

for in WMPs in coastal areas. To allow flexibility in the analysis due to the range of increases within the different time periods, an approach that uses incremental increases of 1, 2, and 3 feet of sea level rise is suggested for modeling. The increments can work as threshold values in planning considerations in terms of allowing planners the ability to know ahead of time where the next set of vulnerable areas will be, to allow for a proactive response approach that can be matched to the observed future rates. Sea level rise is a major concern since nearly half the US population lives within 50 miles of the coast, involving most major commercial, residential, and economic enterprises. The effects of 5 ft sea level rise, King tide, and 1-day 100-year storm event are shown in **Error! Reference source not found.**.

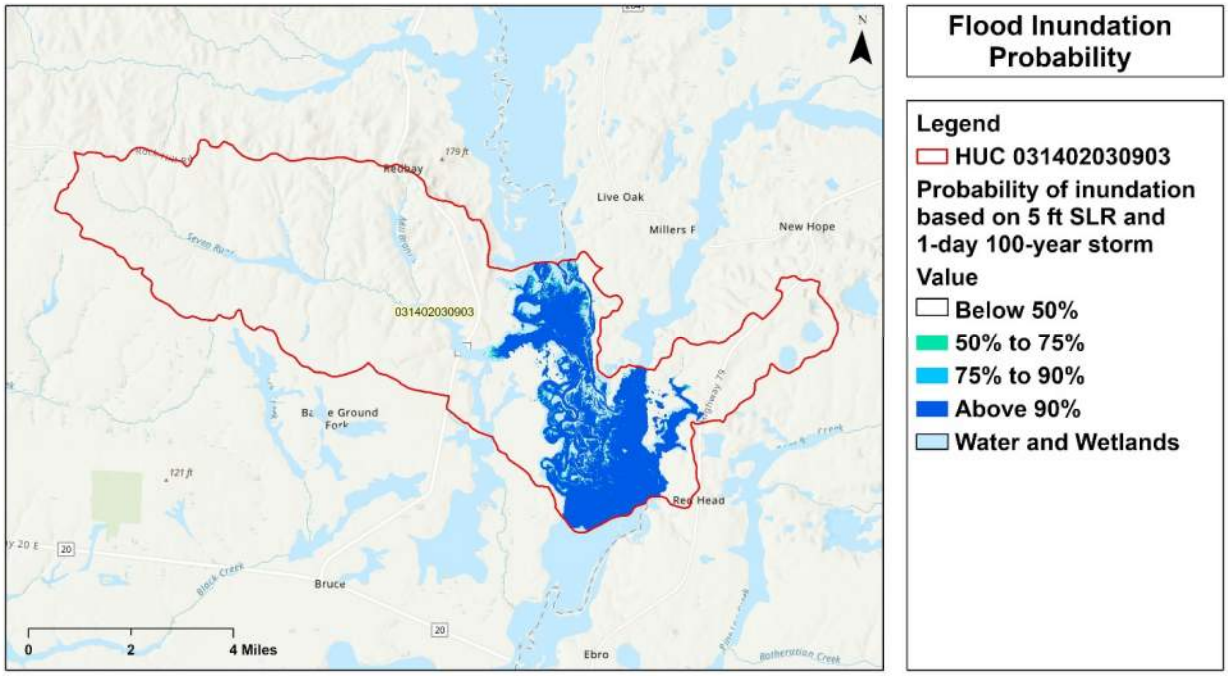

Figure 34. Flood Inundation Probability for a Sea level rise of 5 ft + 1-day 100-year storm event for HUC 031402030903 sub-watershed.
Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations. Dark blue is area under 5 ft NAVD88 and potentially inundated at the 99th percentile tidal conditions. Processed by FAU.

2.4 Modeling Results

Error! Reference source not found. to **Error! Reference source not found.** are a series of maps that depict risk of flooding in the basin based on the following scenarios:

1. **3-day 25-year storm event**. Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 35)
2. **1-day 100-year storm event**. Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 36)
3. **1-day 10-year storm event.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 37)
4. **1-day 5-year storm event.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 38)
5. **Sea level rise of 1 ft + 3-day 25-year storm** (only coastal area and GW affected – GW layer rises 1 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 39)
6. **Sea level rise of 1 ft + 1-day 100-year storm** (only coastal area and GW affected – GW layer rises 1 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations storm (Figure 40)
7. **Sea level rise of 1 ft + 1-day 10-year storm** (only coastal area and GW affected – GW layer rises 1 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 41)
8. **Sea level rise of 1 ft + 1-day 5-year storm** (only coastal area and GW affected – GW layer rises 1 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 42)
9. **Sea level rise of 2 ft + 3-day 25-year storm** (only coastal area and GW affected – GW layer rises 2 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 43)
10. **Sea level rise of 2 ft + 1-day 100-year storm** (only coastal area and GW affected – GW layer rises 2 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 44)
11. **Sea level rise of 2 ft + 1-day 10-year storm** (only coastal area and GW affected – GW layer rises 2 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 45)
12. **Sea level rise of 2 ft + 1-day 5-year storm** (only coastal area and GW affected – GW layer rises 2 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 46)
13. **Sea level rise of 3 ft + 3-day 25-year storm** (only coastal area and GW affected – GW layer rises 3 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 47)
14. **Sea level rise of 3 ft + 1-day 100-year storm** (only coastal area and GW affected – GW layer rises 3 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 48)

15. **Sea level rise of 3 ft + 1-day 10-year storm** (only coastal area and GW affected – GW layer rises 3 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 49)
16. **Sea level rise of 3 ft + 1-day 5-year storm** (only coastal area and GW affected – GW layer rises 3 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 50)
17. **Sea level rise of 4 ft + 3-day 25-year storm** (only coastal area and GW affected – GW layer rises 4 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 51)
18. **Sea level rise of 4 ft + 1-day 100-year storm** (only coastal area and GW affected – GW layer rises 4 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 52)
19. **Sea level rise of 4 ft + 1-day 10-year storm** (only coastal area and GW affected – GW layer rises 4 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 53)
20. **Sea level rise of 4 ft + 1-day 5-year storm** (only coastal area and GW affected – GW layer rises 4 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 54)
21. **Sea level rise of 5 ft + 3-day 25-year storm** (only coastal area and GW affected – GW layer rises 5 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 55)
22. **Sea level rise of 5 ft + 1-day 100-year storm** (only coastal area and GW affected – GW layer rises 5 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 56)
23. **Sea level rise of 5 ft + 1-day 10-year storm** (only coastal area and GW affected – GW layer rises 5 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 57)
24. **Sea level rise of 5 ft + 1-day 5-year storm** (only coastal area and GW affected – GW layer rises 5 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 58)

In all scenarios, a considerable amount of flooding is noted at the river entrance to the HUC, extending to the wetland areas. Given that this basin is connected to the ocean through the Choctawhatchee River, SLR scenarios plays an important hole, implying a considered growth as the projected scenario of rising tides rises.

The design storm simulation determined that approximately 3.1% of the HUC total area or 1.44 mi^2 has a probability of inundation above 50% for a 3-day 25-year design storm. For comparison, approximately 3.3% of the HUC's total area, or 1.52 mi^2 would be expected to be inundated during a 1-day 100-year design storm. Approximately 3.1% of the HUC's total area, or 1.44 mi^2, would

be expected to be inundated during a 1-day 10-year design storm. Finally, approximately 3.1% of the HUC's total area, or 1.44 mi^2, would be expected to be inundated during the 1-day 5-year storm. **Error! Reference source not found.** compares the four storm events.

Table 7. HUC 031402030903 expected inundated area by storm event.

Storm Event	Area with probability of inundation below 50% (Sq Mi)	Area with probability of inundation above 50% (Sq Mi)	Area with probability of inundation below 50% (%)	Area with probability of inundation above 50% (%)
3-day 25-year	45.19	1.44	96.9%	3.1%
1-day 100-year	45.10	1.52	96.7%	3.3%
1-day 10-year	45.19	1.44	96.9%	3.1%
1-day 5-year	45.19	1.44	96.9%	3.1%

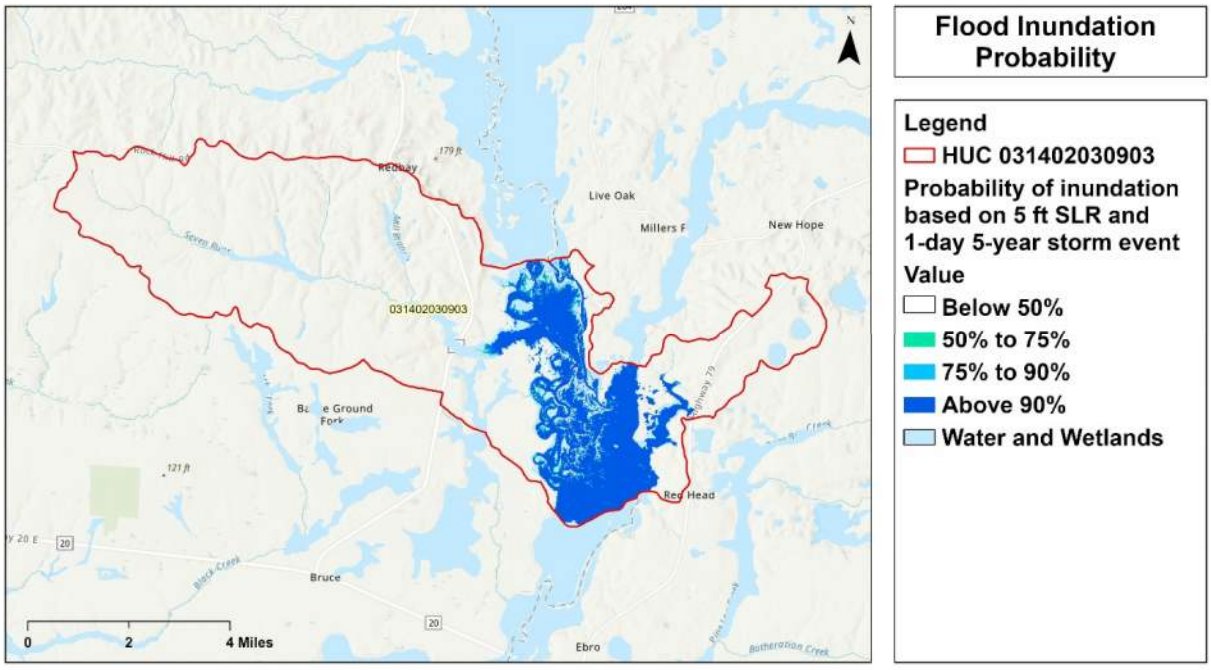

Figure 58. Sea level rise of 5 ft + 1-day 5-year storm for HUC 031402030903 sub-watershed. Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations. Processed by FAU.

2.5 Risk and Vulnerability

The screening tool modeling exercise from the prior section identified areas within the communities that are vulnerable to flooding. Higher priority concerns should be those properties or assets that are considered essential and need to be kept in service during a flooding event. All other improvements are local. To help with prioritization, the following is suggested:

- Tier 1 - Critical facility protection (water/sewer utilities, public safety, hospitals, schools, power, shelters)
- Tier 2 - Essential facilities (groceries, pharmacies, roadways)
- Tier 3 - Economic centers (protecting jobs)
- Tier 4 - At risk communities
- Tier 5 - Other urban/suburban property
- Tier 6 - Agriculture/public property/vacant/undeveloped

Error! Reference source not found. outlines the priority of land use based on DOR land use codes from the property appraiser's office and assigns an associated priority level to each parcel. Note that for residential property, identifying at-risk communities (income, age, disability, health)

requires a further drilldown to the neighborhood level (i.e. wealthy neighborhoods with few older, poor health individuals would have a lower priority than at risk communities, which generally have lower value housing and denser development). In the latter case, more people are impacted, and those people have less ability to mitigate risk. Based on these priorities, the relative risk priority DOR land use codes were evaluated based on a scale of 1 to 6, where 1 is higher priority (more vulnerable) and 6 is the least priority (least vulnerable).

Table 8. Priority of Land Use based on (DOR) land use codes. Processed by FAU.

DOR (Use code)	**Description**	**TIER (Priority of Land Use)**

101	Parcels With no Values (ROW - avenues, highways, arterials)	2
102	Parcels With no Values (Water)	6
103	Parcels With no Values (Rail)	2

Having assigned the risk priority from 1 to 6 in the DOR codes and the percentage of the parcel that floods during the applicable design storm, properties that are more critical to the function of the community can be identified. The methodology is to first convert the DOR code priority tier to its inverse scale by the following equation:

Consequence of risk factor = 7 – DOR Code Priority Tier

The flood risk factor from the screening tool is interpreted based on flooding probability. We take all parcels in tiers #1-4 that have a greater than 50% chance of flooding during a particular design storm and calculate the percent of the parcel that would flood during that event. The percentage is converted to a 6-point scale termed as the Flood Risk Factor, shown in **Error! Reference source not found.**.

Table 9. Flood Risk Factor Classification.

Percent of Parcel Flooded	Flood Risk Factor
90-100%	6
80-89%	5
70-79%	4
60-69%	3
50-59%	2
<50%	1

The priority is further developed by assigning 75% of the importance to the consequence of flooding and 25% importance to flood risk, or three times the importance to the consequence of flooding to come up with a composite score as follows:

Flood Risk Factor × 25% + Consequence of Risk Factor × 75% = Composite Score

Example: 1 × 25% + 6 × 75% = 4.75

Those higher priority properties that received the higher composite score are where the mitigation strategies and financial resources should focus first.

2.5.1 Results

Error! Reference source not found. to **Error! Reference source not found.** depict the HUC 031402030903 sub-watershed priority of land uses showing the critical facilities that should receive priority. The first map (**Error! Reference source not found.**) exclusively displays critical facility parcels within the HUC without any flooding. The second map (Figure 60) overlays critical facilities onto the 1-day 100-year storm event scenario, while the third map (**Error! Reference source not found.**) represents the same overlay within the context of 5 feet of sea level rise (SLR) combined with the 1-day 100-year storm event. **Error! Reference source not found.** is a mosaic showing critical facilities overlaid in the 5 feet SLR + 1-day 100-year storm event for the whole county.

Additionally, **Error! Reference source not found.** and **Error! Reference source not found.** illustrate the composite score for the HUC, which is the result of the calculations explained above, pinpointing parcels that should be prioritized. It considers only parcels classified as 1 to 4 tiers, and within the 50% probability of inundation area. **Error! Reference source not found.** represents the calculation for composite score based on 1-day 100-year storm event, while **Error! Reference source not found.** shows the calculation for composite score for the same storm event, but including a 5 feet of Sea Level Rise scenario. **Error! Reference source not found.** shows the same area zoomed out.

Please note that the composite score results display outcomes exclusively for parcels within the flooding path area. Consequently, for parcels outside this flooding path, the composite results will be null. The composite score combines the flooding path area with the land use priority results to identify the most vulnerable areas deserving of priority.

2.5.2 Solutions

Chapter 5 of the Watershed Master Plan for Walton County describes a list of possible gray and green stormwater strategies to combat flooding that can be implemented as solutions for the county. The same solutions can also be applied at the HUC level, including HUC 031402030903. A summary of these flood mitigation strategies is listed in **Error! Reference source not found.**. For more detailed information, please see Chapter 5-5.3 (Solutions).

Table 10. List of possible gray and green stormwater strategies to combat flooding.

Strategy Class	Implementation Strategy	Applications	Benefits	Cost	Barriers to Implementation
Green	Rainwater harvesting	Local, small scale, easily implemented in developed areas	Protects property, treats runoff	Under $5,000	Limited volume disposed of, so many are needed, maintenance
Gray	Pervious paving	Parking lots, patios, driveways, anything except paved roads due to traffic loading	Reduces roadway and parking lot flooding	$10-20/sf, requires bumpers and sub-base to maintain paver integrity	Must be maintained via vacuuming or the perviousness fades after 2-3 years
Green	Detention	Common for new development, but difficult to retrofit; limited to open areas	Removes water from streets, reduces flooding	$200K/ac	Land availability, maintenance of pond, discharge location Uses up land that could otherwise be developed
Gray	Exfiltration Trench	Any low-lying area where stormwater collects and the water table is more than 3 ft below the surface; densely developed areas where retention is not available, roadways	Excess water drains to aquifer, some treatment provided	$250/ft	Significant damage to roadways for installation, maintenance needed, clogging issues reduce benefits
Gray	Central sewer installation	All areas where there are septic tanks. Mostly a water quality issue	Public health benefit of reducing discharges to lawns, canals, and groundwater from septic tanks	$15,000 per household	Cost, assessments against property owners, property rights issues

Strategy Class	Implementation Strategy	Applications	Benefits	Cost	Barriers to Implementation
Green	Flood prone property acquisition	Regional agency - could be any low-lying areas	Removes flood prone areas from risk	$2K-$100K/ac depending on whether it is already developed	Difficult to implement if occupied, issues with willing sellers, cost, lack of funds for acquisition
Gray	Pump stations	Any low-lying area where stormwater collects, and there is a place to pump the excess stormwater to such as a canal; common for developed areas	Removes water from streets, reduces flooding	Start at $1.5 to 5 million each, number unclear without more study	NPDES permits, maintenance cost, land acquisition, discharge quality
Gray	Armored sewer systems	Any area where gravity sanitary sewers are installed	Keeps stormwater out of sanitary sewer system and reduces potential for disease spread from sewage overflows	$500/manhole	Limited expense beyond capital cost
Gray	Sea walls	Barrier islands and downtown coastal areas	Protects property	$1200/ft	Private property rights, neighbors
Policy	Changes in land use	Applicable universally	Achieves flood risk mitigation by adjusting permitted land use	Low but may incur private property rights conflicts and litigation	Private property rights conflicts and litigation
Gray	Roadway base protection	Low-lying areas, coastal communities	Protects roads and access routes	$1 million per lane-mile	Cost, adjacent properties become uninsurable
Policy	Enhanced elevation of buildings	Developers would implement this for new construction	Reduced flood risk	Varies	Potential issues with building structure or latticework, and existing homes that are not elevated

2.5.3 Impacted Adjustment Areas

In the evaluation of flood risk management strategies within the framework of the National Flood Insurance Program Community Rating System (CRS), the concept of impact adjustment plays a pivotal role in determining the extent to which CRS-credited activities or elements influence the vulnerability of a community's Special Flood Hazard Area (SFHA) and the structures located within it. It is important to note that while the usual results of impact adjustment are related to the SFHA area, in this specific analysis, it was used 1-day 100-year storm event inundation area performed by FAU instead.

In this context, the following table presents a breakdown of the impact adjustment calculations for a 1-day 100-year storm event inundation. The values are expressed in acres and depict the areas of interest as well as the deductions considered in the evaluation process.

The outcomes of these calculations provide valuable insights into the impact adjustment scenarios:

With ALL State Lands:

This scenario reflects the remaining inundation area after accounting for deductions A, B, and C. It represents the effect of CRS-credited activities without considering the influence of state lands in managing flood risks.

With NO State Lands:

In this case, the remaining inundation area is determined by considering all deductions, including state lands (both open space and not open space– see **Error! Reference source not found.**).

These calculations highlight the dynamic nature of impact adjustment within the CRS framework. By accurately gauging the influence of individual elements, the system ensures that credit allocations align closely with a community's efforts in flood risk mitigation.

Table 11. Impacted Adjustment Areas for HUC 031402030903. Processed by FAU.

AREAS	**ACRES**
HUC-12 Sub-watershed: 031402030903	29841.40
All of the 1-day 100-year storm event inundation	**975.39**
Subtract	
A. Bodies of Water in 1-day 100-year inundation > 10 acres	773.18
B. Federal Land in 1-day 100-year inundation > 10 acres	0.00
C. Reservation/Tribal Land in 1-day 100-year inundation > 10 acres	0
D. State Land in 1-day 100-year inundation > 10 acres that is open space	153.43
E. State Land in 1-day 100-year inundation > 10 acres that is NOT open space	1.17
The remainder is either:	
With ALL State Lands: All of the 1-day 100-year inundation minus (A+B+C) or	202.20
With NO State Lands: All of the 1-day 100-year inundation minus (A+B+C+D+E)	47.60

2.5.4 Repetitive Loss Property Map

A Repetitive Loss (RL) property is a building that has had two or more loss or damage due to a specific hazard, such as floods, hurricanes, or other natural disasters, over $1,000 each, paid by the National Flood Insurance Program (NFIP) within any ten-year period since 1978. There are more than 122,000 RL properties in the nationwide (FEMA, 2005).

These data are essential for assessing the vulnerability of certain areas to recurrent losses and for developing strategies to mitigate the risks. However, due to privacy concerns, the data cannot be openly shared with the public. For this reason, the data were converted into a hot spot analysis map. These maps, instead of identifying the specific location of the repetitive loss properties, highlight clusters of repetitive loss claims and areas where the probability of repetitive losses is higher than would be expected by random chance. In other words, it helps pinpoint locations that have a higher concentration of properties prone to repetitive losses. **Error! Reference source not found.** indicates the results from hot spot analysis in point data, showing aggregated counts, and raster data, showing the estimated probability of repetitive loss.

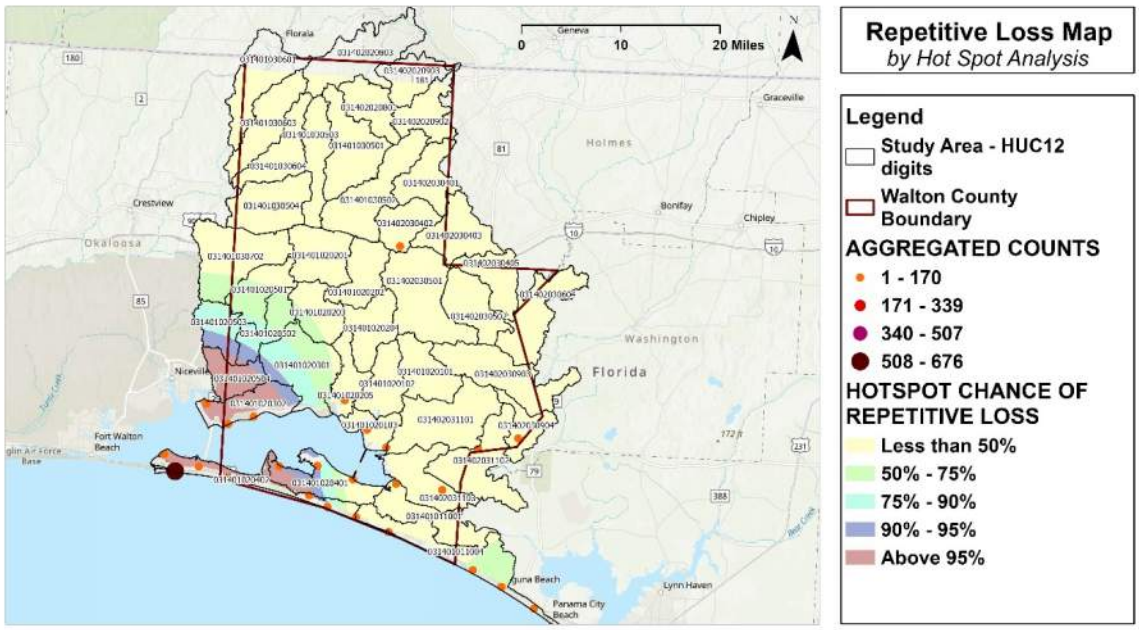

Figure 66. Repetitive Loss map for Walton County by Hot Spot Analysis. Processed by FAU.

2.5.5 Priority Projects

The basin does not feature a significant amount of developed land. While there are some parcels falling within tiers 1, 4, and 5 of land use priority classifications within the basin, only three of them, classified as tier 5, fall within the flooding zone. This is despite the presence of substantial flooding in both 1-day 100-year storm events and 1-day 100-year + 5 feet sea-level rise scenarios. It is worth noting that there are 13 parcels classified as utilities within Tier 1 of priority land use, but fortunately, none of them are within the flooding zone.

Consequently, when considering the composite score, it is notable that the results are null, indicating no priority for intervention within the basin.

X.0 EXECUTIVE SUMMARY

The goal of the appendices to the watershed plan are to outline the issues associated with the individual HUC12s that contribute or impact the community's flood vulnerability and there for its flood protection efforts. Floodplain analysis includes developing a watershed model and identifying associated inundation polygons. It builds upon information generated from the watershed evaluation so that planning and management decisions can be formulated.

This appendix describes the issues and modeling associated with one of the HUC12s that affects Walton County. In developing the County-wide plan, this HUC 12 was analyzed so as to determine how it brings or removes floodwaters from the County. For the NFIP process the goal is to analyze all communities at the HUC12 level. From a community perspective the HUC12 is less useful to residents than a community-wide plan. Hence in all cases the HUC12 results were mosaicked into the community-wide plan. Details can be found in the HUC12 appendices, some of which were brought into the community plan.

To reduce redundancy, information of the plans, ordinances, policies and regulations were rolled up to the community-wide plan and will not be repeated in the appendices. Likewise, the community wide mapping was parced for HUC12 use.

1.0 WATERSHED CHARACTERIZATION

In this section, key aspects of the watershed are characterized. This is important for later being able to identify the most vulnerable areas and to mobilize resources to implement an action plan. Understanding the characteristics of the watershed involves gathering existing information and data sets from previous planning efforts. It is important to note that this step is iterative and ongoing as new data are generated and projects are implemented and monitored.

To assess the historical and current conditions of the study area, the following existing data sets that characterize the physical and natural features of the watershed were obtained for each HUC-12 sub-watershed in the study area:

- Topographic data (LiDAR)
- Relevant waterway locations
- Groundwater levels
- Soils data
- Land uses including vacant land, wetlands, impervious, etc.
- Precipitation records
- Catchment delineations for flood routing

In addition, the FEMA flood maps must be obtained, and the storm of interest must be identified for screening purposes (1-day 2-year, 5-year, and 100-year events as well as the 3-day 25-year storm event to achieve class 4 in the CRS Manual). In developed areas, many sources of data are already available – the key is putting the key datasets in a format that can queried for screening to identify the priority areas of the watershed. Table 6 is a summary of datasets available at cwr3.fau.edu that were used to construct this plan.

This watershed master plan is a drilldown of the larger Walton County TMDL region, which involves 42 HUC 12-digit sub-watersheds (**Error! Reference source not found.**). **Error! Reference source not found.** shows Walton County Drainage Network and the location of urban areas (cities and towns). In **Error! Reference source not found.**, the HUC-12 digits (031402030904) is highlighted among all the HUCs to help identifying its location. (Figure 3).

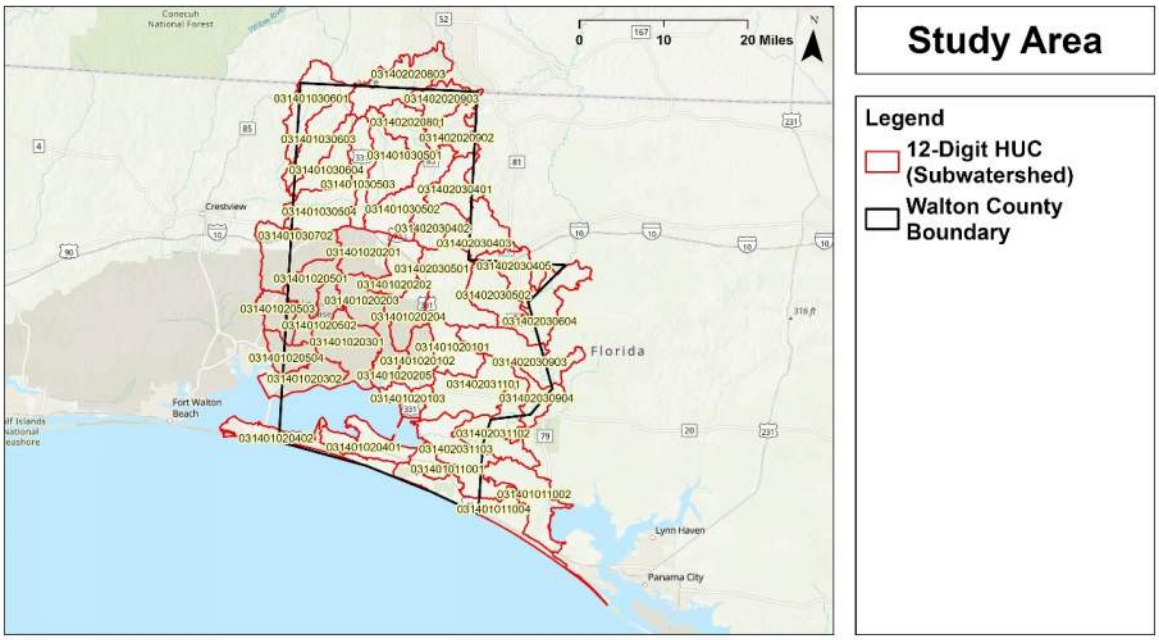

Figure 1. Walton County and all HUCs 12-digit sub-watershed, processed by FAU.

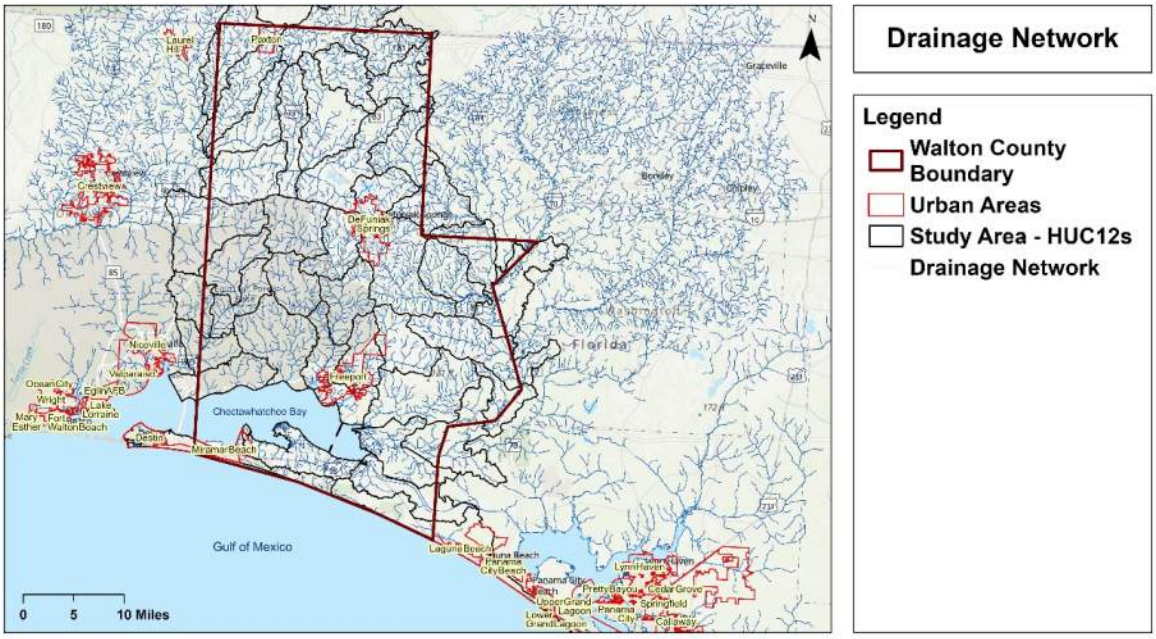

Figure 2. Walton County Drainage Network and urban areas (cities and towns), processed by FAU.

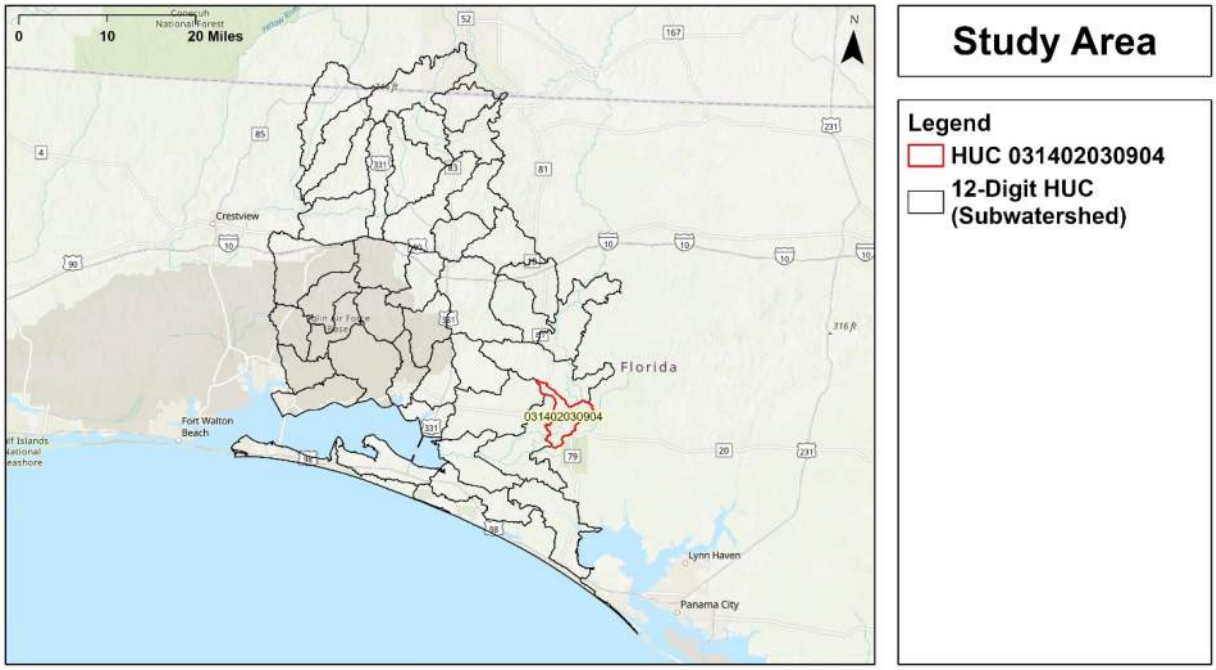

Figure 3. HUC 031402030904 sub-watershed location.

Located in the northwestern region of Florida, Walton County has 1,037.7 square miles of land and it is the 12th largest county in Florida by area, while also sits the highest point in the state, with a height of 345 feet in its northern end. With a population of 75,305 residents according to

the 2020 census and an estimate population in July of 2022 of 83,304, the county has experienced consistent growth within the past several years, driven by factors such as tourism, retirement migration, and regional population dynamics. The county was the residence for 55,043 people according to Census 2010, which leads to a percent change of 36.8% in 10 years, between 2010 and 2020, and a percentage change of 10.6% in two years, between 2020 and 2022 (United States Census Bureau).

The surge in population, particularly in the southern part of Walton County, has resulted in a corresponding expansion of infrastructure to cater to the growing needs. Essential facilities such as potable water systems, wastewater treatment plants, electrical utilities, roads, and schools have been developed to support this increasing population. However, the infrastructure expansion has brought about a significant change in the natural environment. Prior to the existing development , tropical cyclone impacts would be mitigated by natural barriers such as vegetated sand dunes, wetlands, and deserted beaches, which would absorb some of the destructive forces. Now, with the proliferation of costly infrastructure and residential dwellings in coastal areas, these storms pose a higher risk of potential damage. The very areas where development is occurring are becoming more vulnerable to the impact of severe storms, highlighting the importance of considering and implementing adequate measures to address potential storm damage in these coastal regions (Walton County Local Mitigation Strategy Plan, 2015).

Demographically, Walton County presents a heterogeneous age distribution, encompassing a blend of younger and elderly cohorts. The median age of approximately 44 years reflects the presence of both younger families and retirees seeking a serene and picturesque environment. Ethnically, the county' population is predominantly White with smaller yet notable populations of Hispanic/Latino, African American, and other racial/ ethnic groups.

Economically, the tourism sector stands as a dominant force in Walton County, constituting 23.4 percent of the workforce, according to Walton County Economic Development Alliance in 2011, due to its renowned beach destinations, such as Santa Rosa Beach, Miramar Beach, and the New Urbanist Communities of Seaside and Rosemary Beach. Following closely behind is the trade, transportation & utilities sector, accounting for 20.3 percent of employment, while construction stands at 10.0 percent in third place. Education, health care services, and public administration also play significant roles within the top five employment sectors, reflecting the diversified economic landscape of the county (Walton County Local Mitigation Strategy Plan, 2015).

The natural environment in Walton County contributes to its distinctive appeal to visitors and tourists. The county's coastal environment along the Gulf of Mexico showcases picturesque vistas, including white sand beaches, undulating dunes, and coastal dune lakes. These lakes, a rarity worldwide, provide unique ecological habitats. Walton County is also committed to environmental conservation, with designated protected areas comprising state parks, forests, and wildlife management zones. These preserved landscapes offer abundant opportunities for recreational activities, including hiking, fishing, and birdwatching.

The presence of wetlands and waterways further enhances the natural attributes of Walton County. Various rivers and creeks alongside Choctawhatchee Bay permeate the landscape, fostering diverse ecosystems and serving as crucial habitats for a wide range of wildlife species. This rich natural heritage encourages exploration and nurtures an appreciation for the environment.

DeFuniak Springs serves as the county seat and boasts a diverse economy. Anchored by sectors such as healthcare, education, retail, government services, and a thriving small business community, DeFuniak Springs offers a range of employment opportunities. Surrounded by the natural beauty of forests, lakes, and wetlands, the city enjoys the presence of Lake DeFuniak, a noteworthy natural resource. With a population of approximately 5,100 residents, DeFuniak Springs is a vibrant city featuring a mix of economic activities. The land area of DeFuniak Springs is approximately 12.6 square miles (32.7 square kilometers).

Freeport boasts a diverse demographic profile, and a developing economy. The city is situated along the shores of Choctawhatchee Bay, which provides opportunities for recreational opportunities and supports local ecosystems. Surrounded by lush forests and intersected by waterways, Freeport enjoys a rich environmental setting. In terms of economics, Freeport's economy is in a phase of growth and diversification, with sectors including healthcare, education, retail, and small businesses. The city is also strategically positioned for future economic expansion due to its proximity to major transportation corridors. Demographically, Freeport is a close-knit community with a population of approximately 2,600 residents, comprising a mix of permanent residents, retirees, and individuals seeking a suburban or rural lifestyle. The city reflects a diverse demographic composition, showcasing a variety of cultures, and backgrounds. Freeport occupies a land area of about 13.6 square miles (35.3 square kilometers)

Further along the coast, Miramar Beach stands as a coastal gem known for its tourism and hospitality industry. Luxury resorts, vacation rentals, gourmet restaurants, high-end retail shops, and entertainment venues thrive within this bustling city. Miramar Beach's main attraction lies in its stunning white sand beaches along the Gulf of Mexico, providing endless opportunities for beach activities and water sports. Its boundaries extend into neighboring Okaloosa County, attracting a blend of permanent residents, vacation homeowners, and rental property occupants. Miramar Beach, including its neighboring areas, covers an estimated land area of around 4.7 square miles (12.2 square kilometers).

Continuing along the Gulf Coast, we encounter Santa Rosa Beach. This coastal community is renowned for its vibrant tourism industry, offering a plethora of accommodations ranging from upscale resorts to charming vacation rentals. Its demography reflects a mix of permanent residents, seasonal visitors, and individuals seeking a coastal lifestyle, resulting in a diverse and dynamic community. Santa Rosa Beach spans a larger area compared to other cities in Walton County, with an estimated land area of approximately 31.2 square miles (80.8 square kilometers).

A summary of the existing CRS classifications for the communities in the study area is listed in **Error! Reference source not found.**. No cities in Walton County are listed in the FEMA Community Rating System Eligible Communities.

Table 1: Community Rating System for Walton County. Effective April 1, 2023.

Community #	**Community Name**	**CRS Class Rating**	**Premium Discount for SFHA**	**% Discount for Non- SFHA**	**Status**
120317	Walton County	6	20%	10	Cycle

(Source Data: FEMA)

Figures 12 and 13 is the county-wide report show the current and projected land use for the County. Based on the 2017 future land use for Walton County, only 7.07% of the land use in the county is urban and built up, and water/wetlands makes up 29.16% of the land use. The majority of land is upland forest, with 48.3%, as shown in **Error! Reference source not found.**.

Table 2. Land Use in Walton County (Prepared by FAU from future land use map) versus land use in the entire watershed

Level 1 Land Use-Land Cover Type	**Area (Acres)**	**Percentage of Total**
Agriculture	52958.94669	7.17%
Barren Land	9242.05986	1.25%
Rangeland	40326.66002	5.46%
Transportation, Communication, and Utilities	11815.69287	1.60%
Upland Forest	356796.0541	48.30%
Urban and Built-Up	52194.79061	7.07%
Water	61593.80508	8.34%
Wetlands	153759.9055	20.82%
Total	**738687.9147**	**100.00%**

(Source Data: (NWFWMD 2017)

Walton County has a history of flooding and has implemented various measures for flooding mitigation over the years (see section 1.12 for more details). The County has experienced flooding primarily due to heavy rainfall events and proximity to large water bodies such as the Gulf of Mexico, Choctawhatchee Bay, and numerous rivers and creeks. The topography of the region, with low-lying areas in the coastal areas and wetlands, also contributes to flood vulnerability. The proximity to the ocean (Gulf of Mexico) makes the county vulnerable to sea level rise. Over the years, Walton County has faced multiple flooding incidents, including:

- March 1997: Heavy rainfall led to significant flooding throughout the county, resulting in property damage and road closures.
- April 2009: Intense storms caused widespread flooding, damaging homes and infrastructure and resulting in the declaration of a state of emergency.
- April 2014: Heavy rainfall caused severe flooding, leading to the evacuation of some residents and the closure of roads.

Today, the goal of a stormwater management system in many communities is to keep the community as a place to live and do business while limiting risk from damage due to flooding. The short-term impacts from stormwater include flooding in low-lying areas and standing water in areas with limited soil storage capacity. Less common, but of increasing frequency, is the potential for extensive inundation of some areas, especially low-lying areas, during periods with high groundwater levels and groundwater impacted by sea level rise. As a result, there is a need to understand the economic impact of flooding events and to create cost-effective stormwater infrastructure and policy solutions to protect property. This means preserving as much property and economic activity as possible without disrupting current activity or expending funds on inappropriate projects with limited long-term or social value.

1.1 Surface Topography

Topography is a key parameter that influences many of the processes involved in flood risk assessment, and thus, up-to-date, high-resolution, high-accuracy elevation data are required. In order to meet the requirements for FEMA Risk Mapping, Assessment, and Planning (RiskMAP), 1-meter (2015 to present) and 1/9 arc-second (~ 3-meter) (2010 -2015) LiDAR DEMs were acquired. The 1 m × 1 m LiDAR tiles were kriged to create a topographic map of the study area (**Error! Reference source not found.**). This accuracy meets the 3DEP Quality Level 2 vertical root mean square error accuracy threshold of ±10 cm for FEMA (Arundel et al., 2015). The LiDAR used for this basin was 2016.

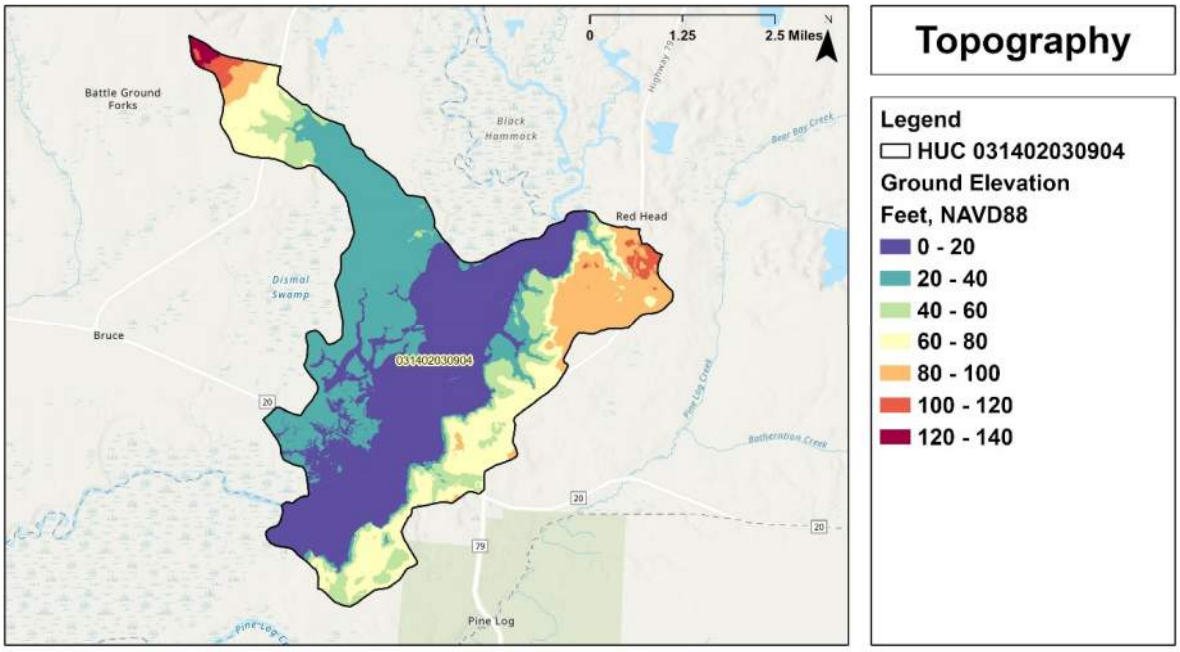

Figure 4. Topographic map of the HUC 031402030904 sub-watershed, processed by FAU. (Data Source: USGS)

1.1.1 Geomorphological Considerations

Walton County's coastal area is characterized by the presence of barrier islands, extensive sandy beaches, and coastal dune systems. These features are influenced by the dynamic processes of wave action, tidal currents, and wind-driven sediment transport. The shoreline is subject to natural changes, including erosion and accretion, which significantly shape the coastal geomorphology. Inland Walton County exhibits a mix of wetlands, forests, rolling hills, and rivers. These landforms are influenced by a combination of factors, including underlying geology, fluvial processes, and the region's hydrological regime.

Like many areas in Florida, Walton County is underlain by limestone formations. The specific composition and properties of these limestone formations in Walton County may vary. However, limestone is generally known for its porous nature, which allows for the absorption and storage of water. Underground aquifers within the limestone formations can hold significant volumes of freshwater, contributing to the region's water resources.

For context, the FIRM panel index of HUC 031402030904 sub-watershed is shown in **Error! Reference source not found.**.

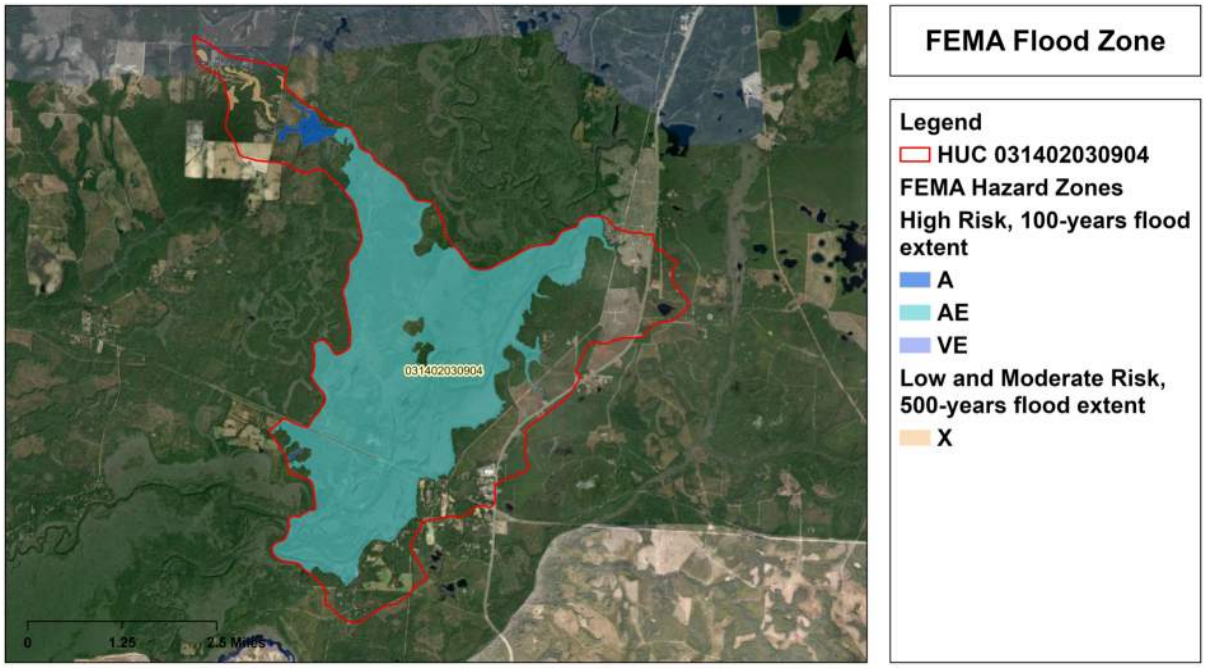

Figure 5. FEMA Flood Zone map (2020) for HUC 031402030904 sub-watershed, processed by FAU.
(Data Source: FEMA)

1.1.2 Waterway Features

In Walton County, Florida, the waterway features are primarily influenced by the presence of rivers, creeks, bayous, and the proximity to the Gulf of Mexico. To the south of Walton County lies the Gulf of Mexico. Sandy beaches, barrier islands, and the open waters of the Gulf itself characterize the coastline along the Gulf. The Gulf of Mexico influences the coastal processes, including wave action, tidal currents, and sediment transport along the shoreline. The combination between sea level rise and King tide would have detrimental consequences for the county costal area, including the sub-watershed 031402030904 as it will reach the area thought Choctawhatchee Bay.

Walton County is home to several rivers and creeks that meander through its landscape. These waterways provide drainage for the inland areas and contribute to the overall hydrological system. Examples of significant rivers in the county include the Choctawhatchee River and the Shoal River. In addition, Walton County features bayous and estuaries that connect inland water systems to the Gulf of Mexico.

Choctawhatchee Bay serves as a vital estuarine ecosystem, where freshwater from rivers and creeks mixes with the saltwater from the Gulf of Mexico, serving as a vital estuarine ecosystem. This unique brackish water environment supports a rich diversity of flora and fauna, including various fish species, shellfish, migratory birds, and wetland vegetation, contributing to the overall biodiversity of the region. It also plays a significant role in the local economy of Walton County as it supports commercial and recreational fishing industries, providing livelihoods for local fishermen and contributing to the seafood industry, while also offering a range of recreational opportunities for residents and visitors alike, such as boating, kayaking, paddle boarding, and sailing. **Error! Reference source not found.** shows the bathymetry offshore.

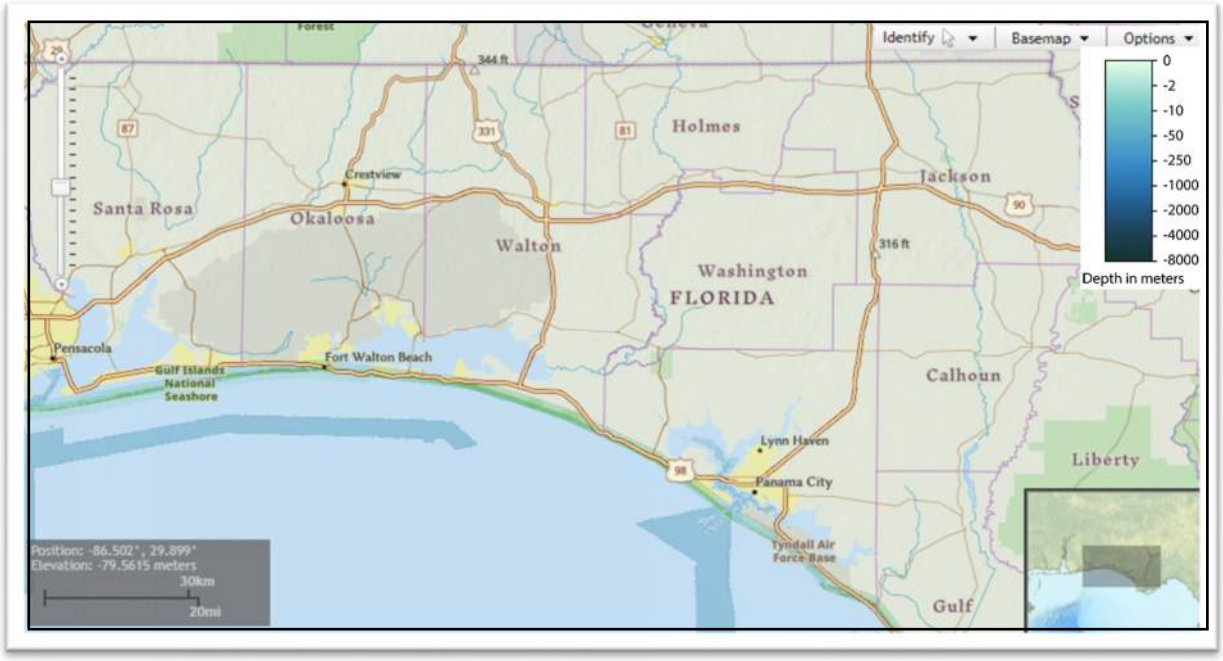

Figure 6. Bathymetry map of the shore of Walton County and surrounding counties of Florida Panhandle.
(Source: ncei.noaa.gov/maps/bathymetry/)

Numerous tributaries exist throughout both the freshwater and estuarine portions of the watershed and can influence the overall hydrology of the area depending on rainfall and regional hydrological conditions. **Error! Reference source not found.** shows the location of all four surface water stations along with ground water stations (wells) and the drainage network of Walton County.

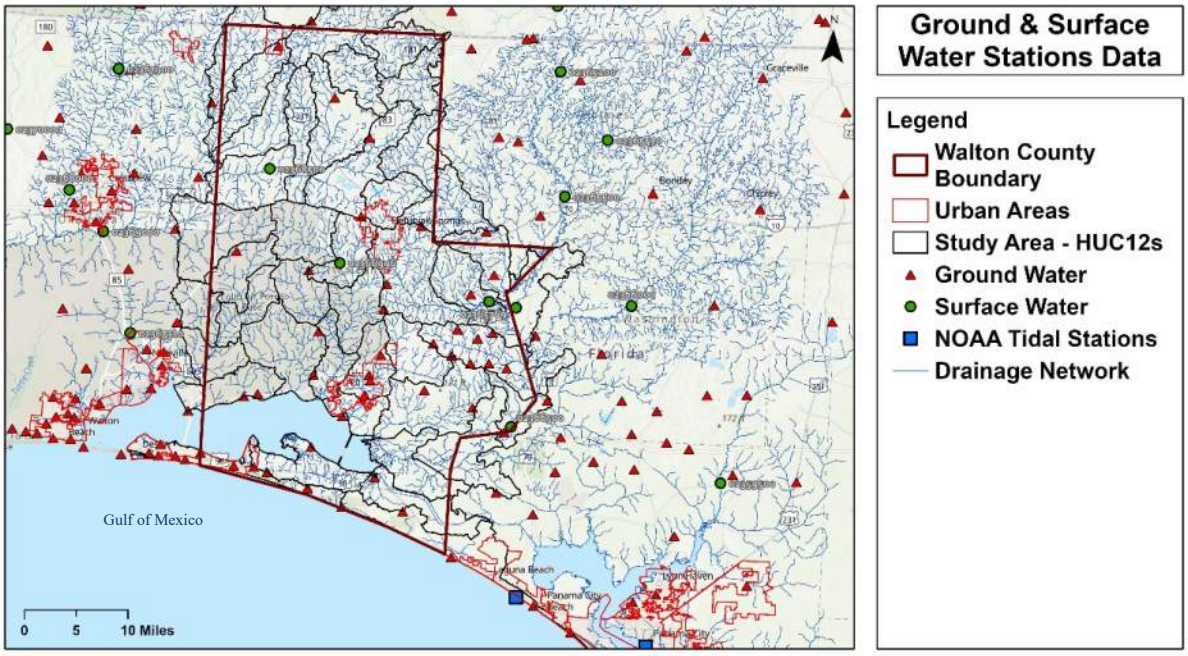

Figure 7. Ground & Surface Water Stations with drainage network for Walton County, processed by FAU.
(Data Source: USEPA – National Hydrographic Dataset (NHD) and NOAA's Tides)

1.1.3 Hydrologic Boundaries

The geographic area of the subject sub-watershed should be clearly defined to ensure that implementing the WMP will address all the major sources and causes of impairments and threats. Although there is no rigorous definition or delineation of this concept, one way to identify the geographic extent of the watershed master planning effort is to consult the United States Geological Survey (USGS) map of hydrologic units. A hydrologic unit is part of a watershed mapping classification system showing various areas of land that contribute surface water runoff to designated outlet points, such as lakes or stream segments. USGS designates drainage areas as sub-watersheds (including smaller drainages) numbered with 12-digit hydrologic unit codes (HUCs), nested within watersheds (10-digit HUCs). These are combined into larger drainage areas called subbasins (8 digits), basins (6 digits), and subregions (4 digits), which make up the large regional drainage basins (2 digits).

Region>>Subregion>>Basin>>Sub-basin>>Watershed>>Sub-watershed

The major water bodies in the HUC 031402030904 sub-watershed include:

- Choctawhatchee River
- Big Cypress Creek
- Graveyard Creek
- Red Head Branch

Given that stream flow data are critical for estimating flooding, **Error! Reference source not found.** shows the historical streamflow during June 2022 to July 2023 for USGS Choctawhatchee River NR Bruce FLA (site number 02366500) within the HUC 031402030904.

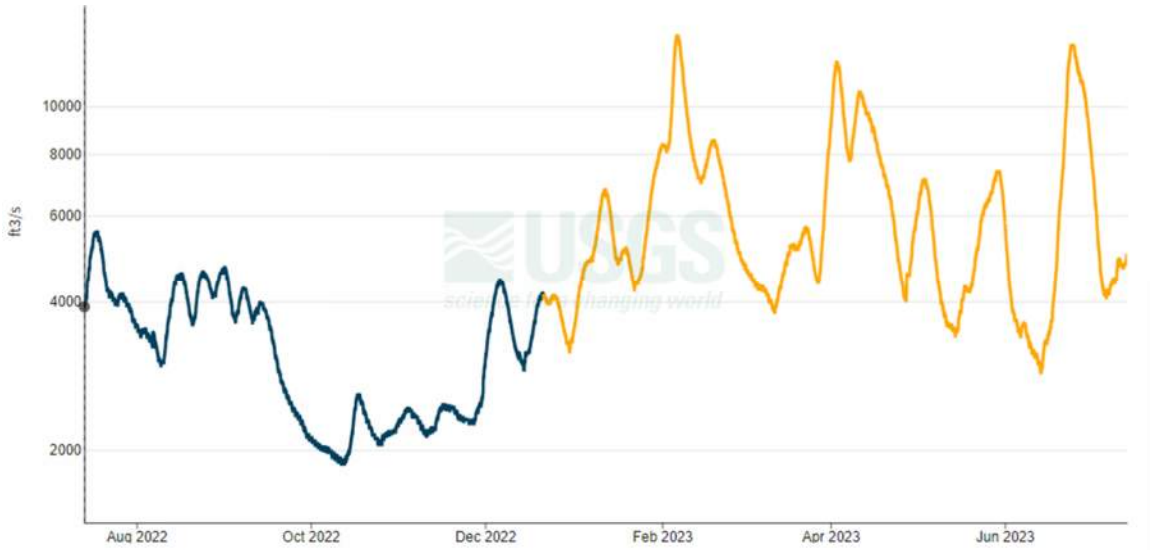

Figure 8. Average streamflow for Choctawhatchee River NR Bruce FLA (USGS 02366500 Surface-Water, June 2022 to July 2023).
(Source: USGS Water Data Services, available at https://waterdata.usgs.gov/monitoring-location/02366500/#parameterCode=00065&period=P365D)

1.2 Groundwater

In this region of Florida, there is a direct interaction between groundwater and surface water. In addition to low land elevations and topographic relief, the groundwater and surface water are controlled by the canals, rivers, and tides. Since there is a limited number of groundwater monitoring stations, the strong relationship between groundwater and surface water was leveraged to develop a 99^{th}- percentile surface of the water table elevation for mapping purposes. To establish a common date for modeling, the recorded groundwater table elevations were sorted in ascending order to determine the 98^{th} - 100^{th} percentile date of occurrence in Excel®, following the procedure detailed in Romah (2011). This procedure was automated for this effort using a python code to process the groundwater data more efficiently. Outliers and anomalous groundwater levels in the database are initially identified (e.g. catastrophic storm events) and replaced by region-specific

mean values based on observations available from the nearest well. Missing date-specific data are estimated using simple temporal interpolation based on observations available in time. If a station (or monitoring well) data contains large amounts of missing data, it is not used in the generation of the groundwater surface.

In Walton County, the average annual rainfall is abundant, reaching 65 inches at DeFuniak Springs. This rainfall predominantly infiltrates the sand-and-gravel aquifer and eventually seeps into streams or the underlying artesian Floridan aquifer. The county's two major aquifers are the sand-and-gravel aquifer and the Floridan aquifer. While the sand-and-gravel aquifer provides water for rural domestic use and plays a crucial role in water storage and streamflow maintenance, it also serves as a recharge source for the Floridan aquifer. Water from the sand-and-gravel aquifer contains varying levels of dissolved solids, pH, and iron content. The Floridan aquifer, being the primary water supply source, underlies the entire county and yields around 500 to 1,000 gallons per minute from wells, except along the Gulf Coast where the permeability is lower. Recharged by leakage from the sand-and-gravel aquifer, the Floridan aquifer's movement is predominantly southward away from the potentiometric high in northwestern Walton County. It discharges through springs, seeps along the Choctawhatchee River, and by wells. In southern Alabama, the Floridan aquifer is directly recharged by rainfall when it is exposed or close to the land surface. (Bureau of Ecology, 1974).

Once a common time period is determined across the majority of shallow groundwater wells, canal data can be gathered for that common date (and two days prior, in the event the canals were deliberately lowered). Data was obtained from the NWFWMD and processed by FAU at cwr3.fau.edu. Between stations, an ArcGIS tool permits a line to be drawn to replicate the canals and establish points in a gradient between stations. The same is true for the ocean, but it is a constant head boundary. The canals form boundary conditions for the screening tool on the edges of the basin and affect localized groundwater. The tide issue is resolved by using the common date for high tide.

Error! Reference source not found. shows the drainage network of HUC 031402030904 and points out the location of the ground water stations in the surroundings. A groundwater-surface layer for the HUC 031402030904 sub-watershed was created using several datasets including water level data from USGS and NWFWMD and groundwater elevation contour maps. The datasets were used to generate a raster surface of the groundwater elevation (**Error! Reference source not found.**).

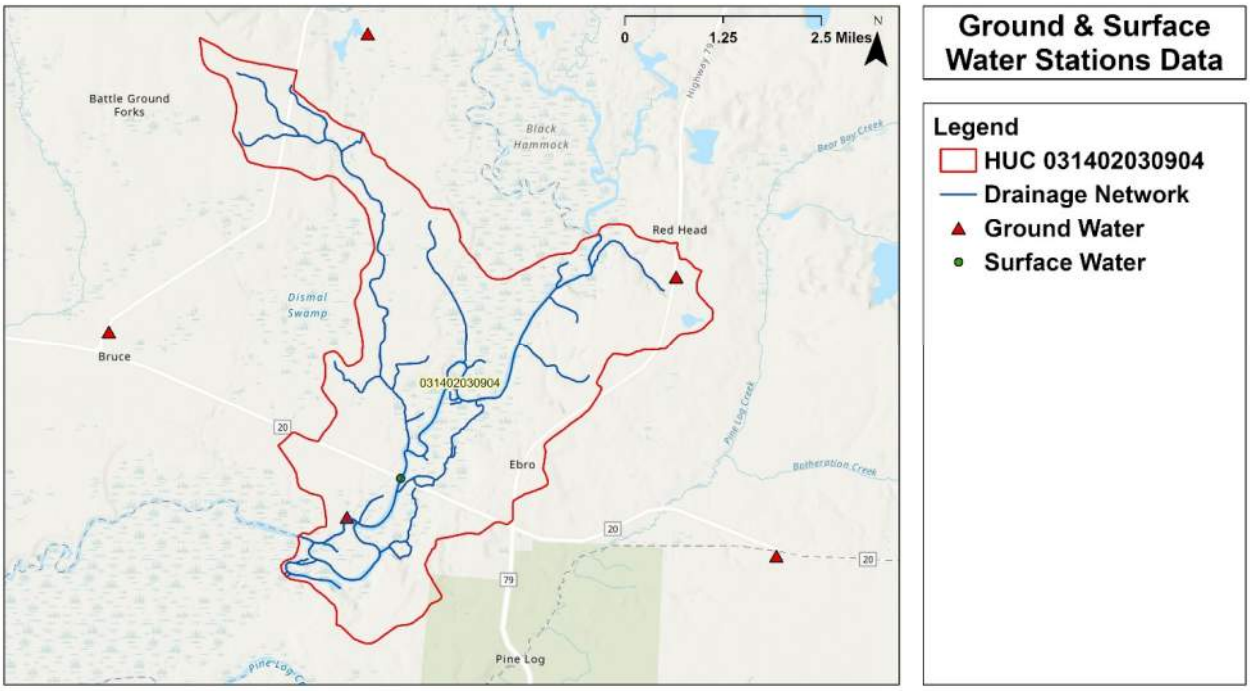

Figure 9. Ground and Surface Water Stations in the HUC 031402030904 sub-watershed, processed by FAU.
(Data Source: USEPA – National Hydrographic Dataset (NHD)

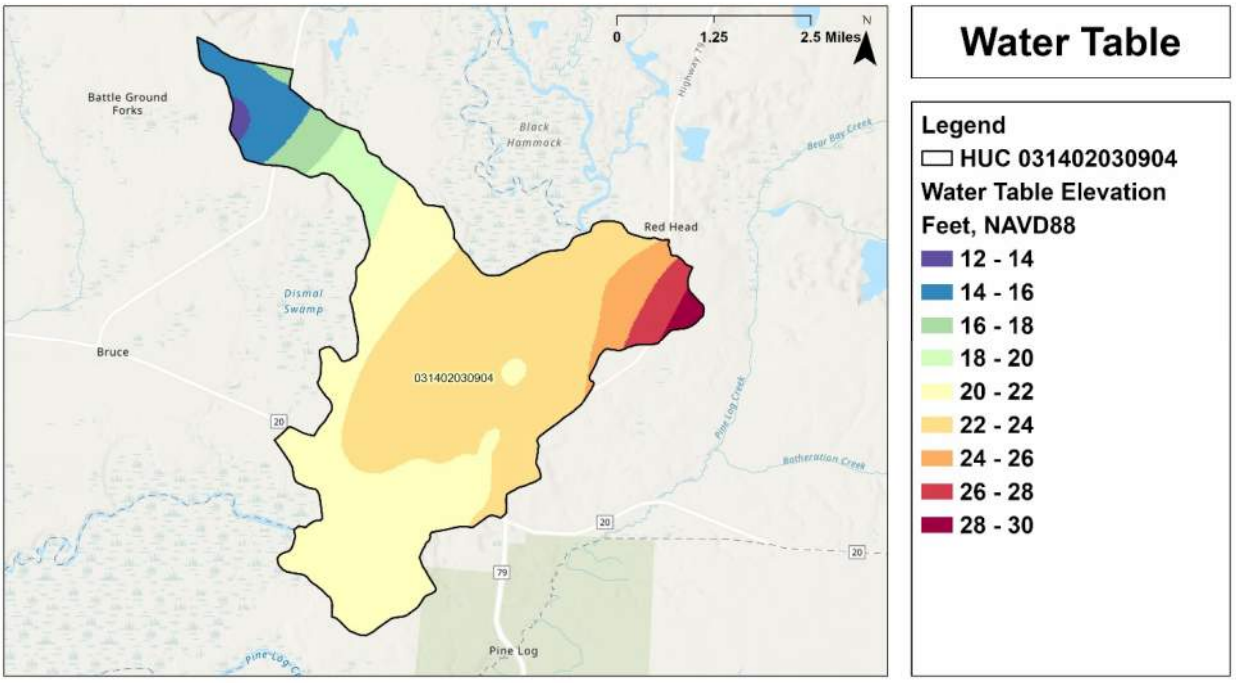

Figure 10. Elevation of the top of the surface groundwater layer for the HUC 031402030904 sub-watershed, created by multiple linear regression analysis – elevation NAVD88, processed by FAU.
(Data Source: USGS and NWFWMD)

1.3 Surface Water/Tides

Historically, surface water and tides have been an important factor in determining how much freshwater is delivered, how fast this water enters wetlands and estuaries, and the quality of that water. Evapotranspiration and rainfall do not coincide in the study area, which makes water supply planning difficult. **Error! Reference source not found.** shows the average precipitation over Walton County for every month of the year between 2011 and 2023- each rectangle is a month and each column is a year. The 12-month total precipitation decreased 7.5 inches from May 1900 to April 2023. From May 1900 to April 2023, the average 12-month total precipitation was 60.5 inches for the entire county.

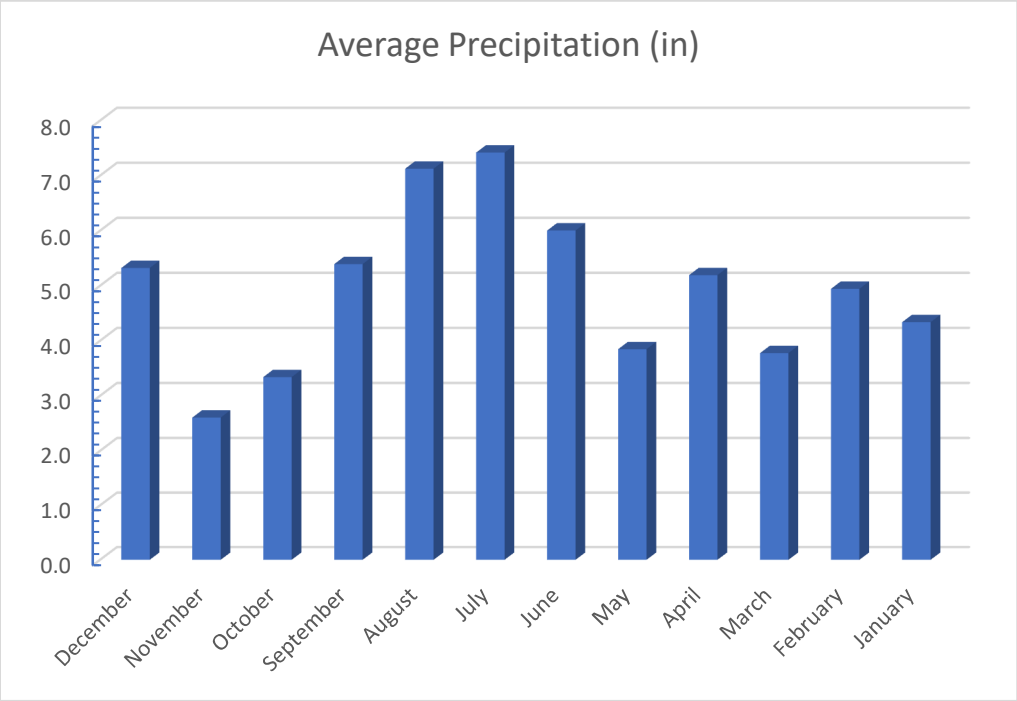

Figure 11. Monthly precipitation in Walton County, FL (2011-2023).
(Data Source: Florida Weather Data, available at https://data.usatoday.com/weather-data/walton-county/12131/1975-04-01/table/)

While the topography (Section 1.1) and native soil (Section 1.4) create an environment that is highly permeable and capable of infiltrating significant percolation into the soil, changes in land use and land cover have resulted in water falling on impervious areas, where the water collects in pools or runs off rapidly, in direct contrast to the natural condition. This runoff flowing over impermeable regions can lead to larger scale flooding.

Tidal data can be gathered from NOAA tidal gages and other gages monitored by local governments. The location of tide gages is important to ensure they accurately depict tides, as opposed to inland waters. To set a boundary for the coastal areas, the high tide on the common date from 12/03/2018 to 12/10/2018 was selected. **Error! Reference source not found.** shows the two closest tide stations to Walton County. Since there is no NOAA tide station in Walton County, the Panama City Beach station (8729210) was used.

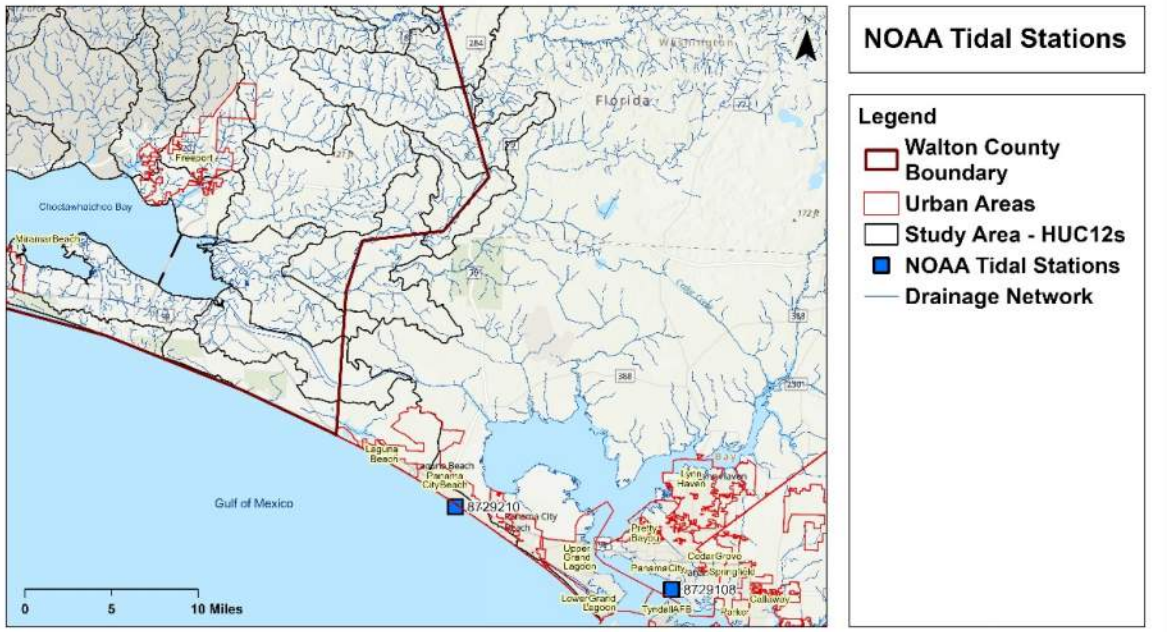

Figure 12. Locations of Florida tidal stations maintained by NOAA near to Walton County, processed by FAU.
(Data Source: USEPA – National Hydrographic Dataset (NHD) and NOAA's Tides)

1.4 Soils

Soil can store water if there is adequate distance between the topographic surface and the groundwater, and the soil types are capable of absorbing the water. Soil storage capacity is the volume of soil pores in the unsaturated zone that is available to store infiltrated stormwater (Gregory et al., 1998). Throughout Florida, it is common to have large volume storm events that fill the voids in the unsaturated zone as shown in **Error! Reference source not found.**.

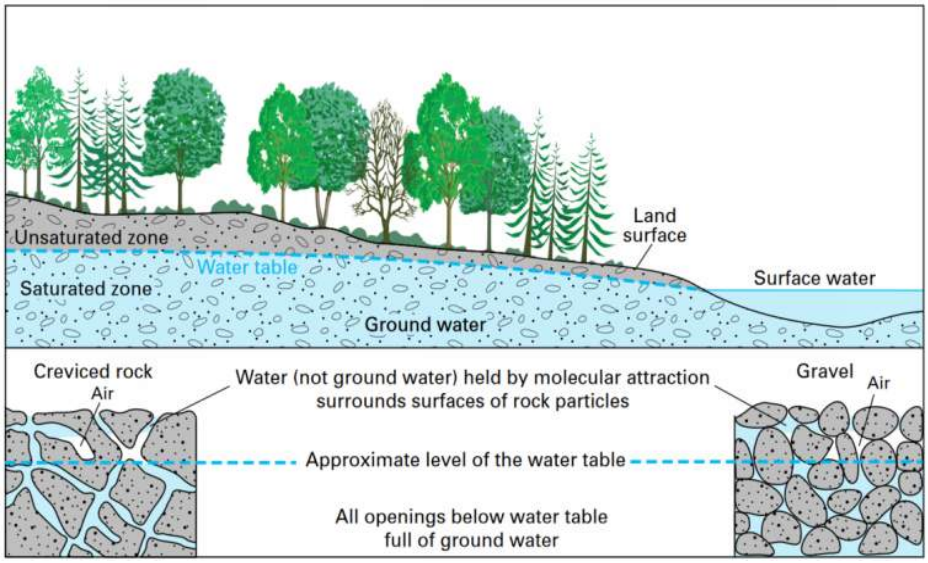

Figure 13. Zones where underground water exists.
(Source: USGS, 2020)

The unsaturated zone is the portion of the subsurface above the water table that contains soil/rock and air and water in its pores as shown in **Error! Reference source not found.**. This zone affects the rate at which the aquifer is recharged by controlling water movement from the surface of the land downward towards the aquifer. During rain events, the soil voids fill up quickly resulting in the water table rising to the surface, and the surplus rainfall becomes runoff.

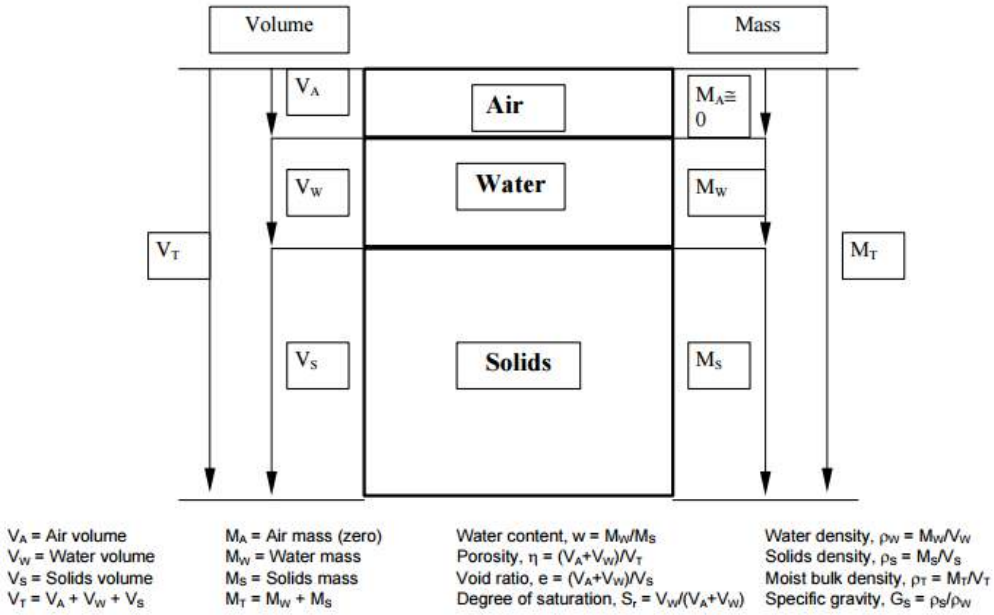

Figure 14. Saturated zone soil phase diagram and definitions.
(Source: Gregory et al., 1998.)

Soil data is available from the United States Department of Agriculture (USDA) or other agencies in the form of maps that can be incorporated as a GIS layer. The Gridded SSURGO (gSSURGO) dataset from USDA is chosen. This dataset is similar to the standard product from USDA Natural Resources Conservation Service (NRCS) Soil Survey Geographic (SSURGO) database, but is in the Environmental Systems Research Institute, Inc. (ESRI®) file geodatabase format. A file geodatabase allows for statewide or even Conterminous United States (CONUS) tiling of data. The gSSURGO dataset contains all of the original soil attribute tables in SSURGO. All spatial data are stored within the geodatabase instead of externally as separate shape files. Both SSURGO and gSSURGO are considered products of the National Cooperative Soil Survey (NCSS). **Error! Reference source not found.** shows the unsaturated zone found by the difference between the groundwater elevation layer and surface topography.

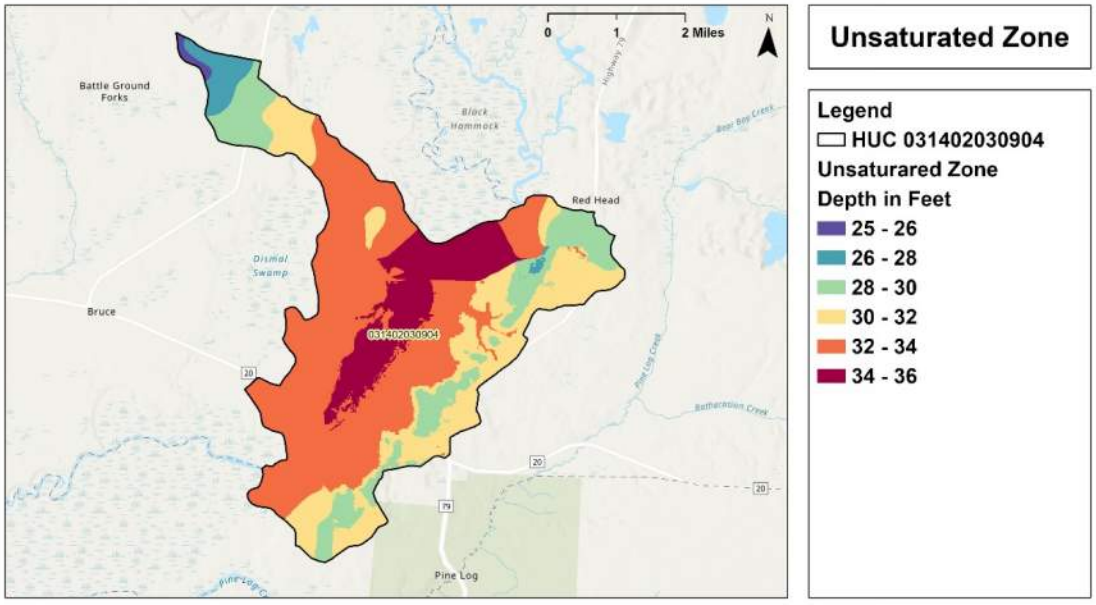

Figure 15. Unsaturated zone map for HUC 031402030904, processed by FAU.

The available water storage from USDA derived for the soil layer (0-150 cm or 0-5 ft) statewide is shown in **Error! Reference source not found.**, which covers most of Florida with a spatial resolution of 10 m. The unit is in cm. As a result of applying this layer to the study area (**Error! Reference source not found.**), the estimated soil storage capacity can be illustrated. A significant portion of the basin demonstrates a moderately favorable soil storage capacity, falling within the range of 28 to 36 feet of remaining capacity.

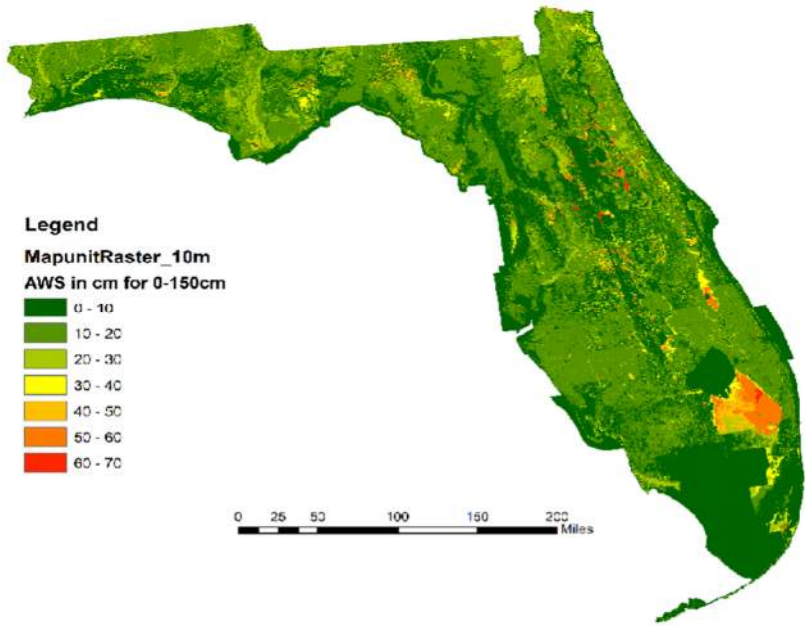

Figure 16. Available water storage derived from the gSSURGO soil database for all of Florida, as processed by FAU.
(Data Source: USDA - SSURGO)

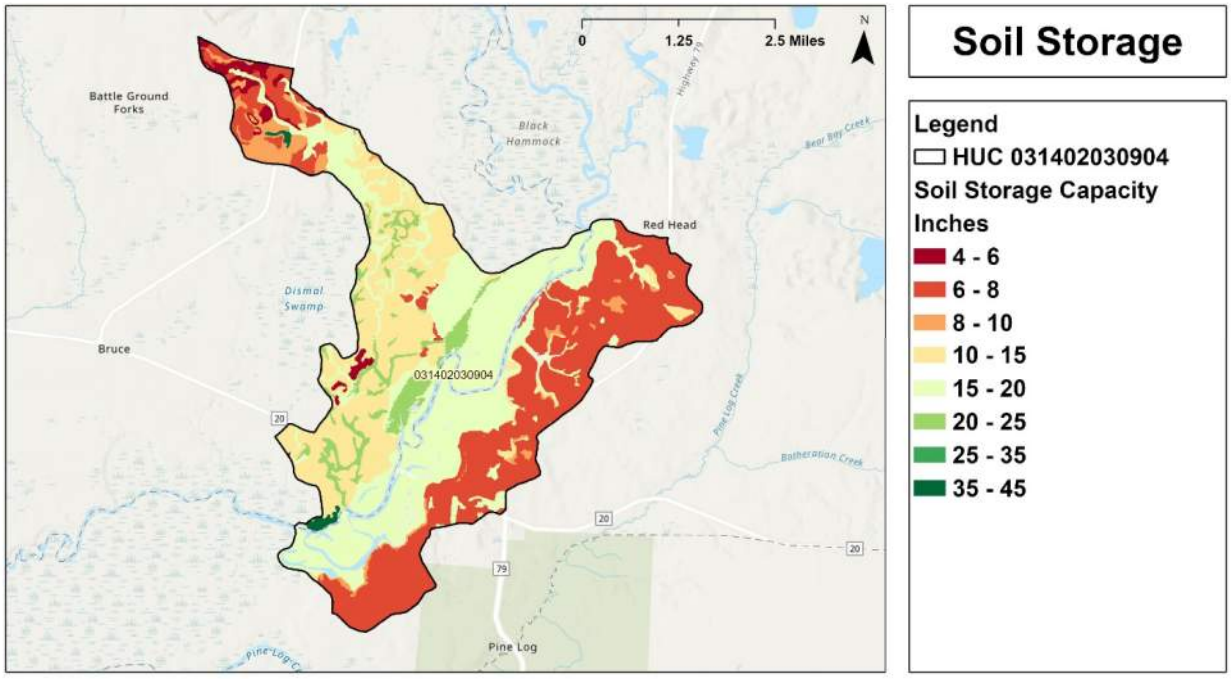

Figure 17. Water storage capacity of soil for the HUC 031402030904, processed by FAU.

Lastly, **Error! Reference source not found.** shows the water holding capacity for the basin, which refers to the capacity of a particular soil texture to retain water against the force of gravity.

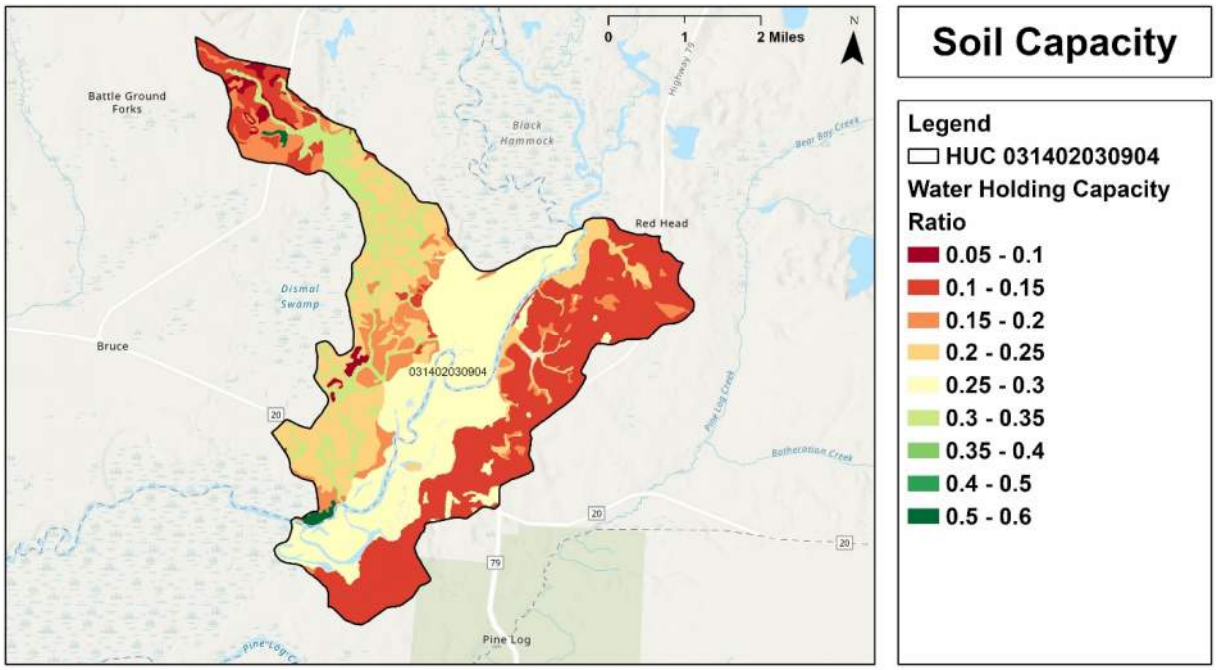

Figure 18. Water Holding Capacity (ratio) for the HUC 031402030904, processed by FAU.

1.5 Land Cover

The USGS produces the NLCD of nationwide data on land cover at a 30-m resolution with a 16-class legend based on a modified Anderson Level II classification system. NLCD is coordinated through the 10-member Multi-Resolution Land Characteristics Consortium (MRLC) to provide digital land cover information nationwide. For the conterminous United States, NLCD 2016 contains 28 different land cover products characterizing land cover and land cover change across 7 epochs from 2001-2016, urban imperviousness and urban imperviousness change across 4 epochs from 2001-2016, tree canopy and tree canopy change across 2 epochs from 2011-2016 and western U.S. shrub and grassland areas for 2016 (**Error! Reference source not found.**).

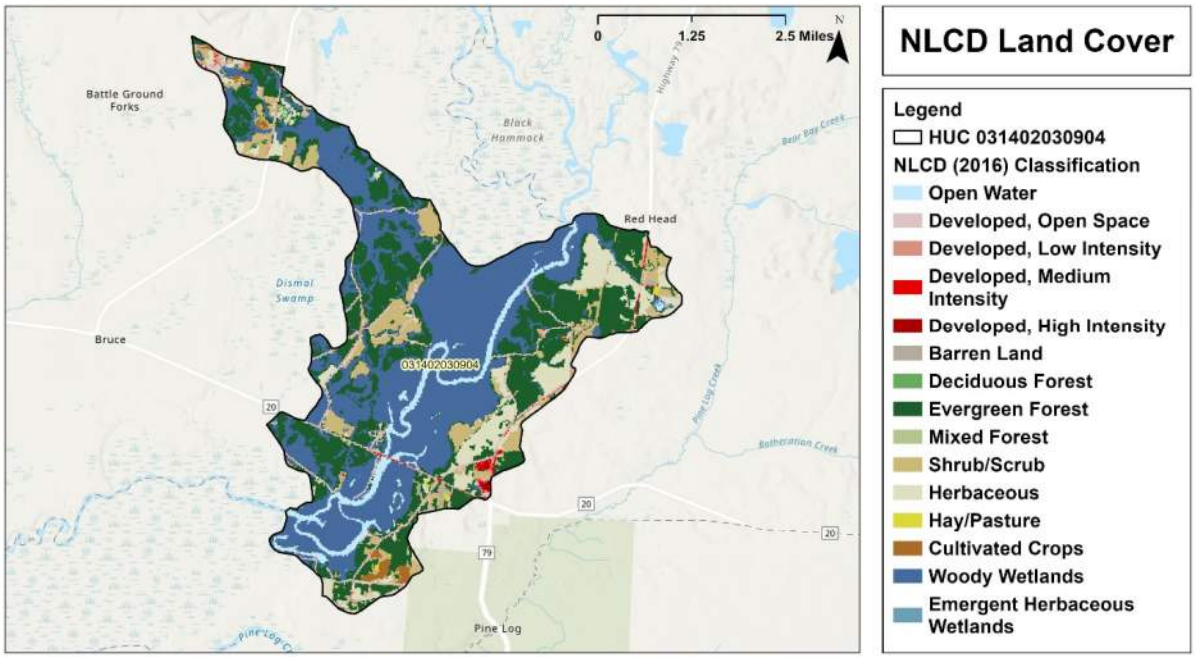

Figure 19. Land use in the HUC 031402030904 (from the NLCD 2016 database), processed by FAU.
(Source Data: NLCD, 2016)

The dataset is derived from the Florida Land Use Cover Classification System (FLUCCS), which is digitized by photo-interpretation on county-based aerial photography with varying resolution in the range of 4 in - 2 ft pixel. The NLCD 2016 has a 30-meter resolution derived from Landsat imagery. Hence, the NLCD maps appear much coarser and pixelated compared to the 2023 Florida Geographic Data Library (FGDL) (https://fgdl.org/fgdlmap/) maps. . A view of the latter is provided in **Error! Reference source not found.**. The future land use maps need to be used for the final land cover, as adjusted for future stormwater improvements set by regulatory standards.

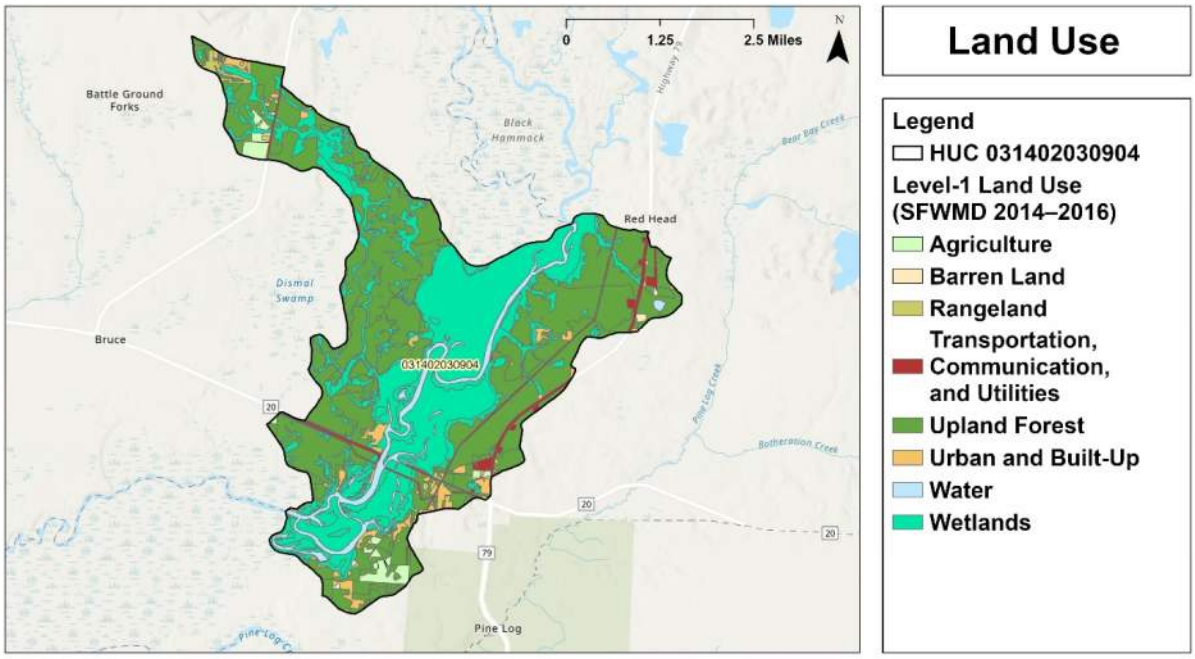

Figure 20. Land use in the HUC 031402030904 processed by FAU.
(Source Data: 2023 Florida Geographic Data Library (FGDL) database))

In the HUC 031402030904 sub-watershed, the predominant land cover is upland forest, accounting for 41.26% of the area. Wetlands comes in second at 30.70%, followed by Transportation, Communication, and Utilities at 12.68%, and water at 12.06%. Developed land constitutes a minor portion, with only 1.35% categorized as urban and built-up, as shown in **Error! Reference source not found.**. **Error! Reference source not found.** shows the roughness of the surface.

Table 3. Land use for HUC 031402030904 sub-watershed

Level 1 Land Use Land Cover Type	**Area (Acres)**	**Percentage of Total**
Agriculture	343.22	1.38%
Barren Land	15.14	0.06%
Rangeland	127.08	0.51%
Transportation, Communication, and Utilities	3142.31	12.68%
Upland Forest	10230.03	41.26%
Urban and Built-Up	335.11	1.35%
Water	2988.58	12.06%
Wetlands	7609.74	30.70%
Grand Total:	**24791.21**	**100.00%**

Table 4. Roughness and CN Values for Each Land Use Code

DOR Code	Use	Impervious %	Roughness
0	Vacant	0	0.4
1	Single Family	29	0.25
2	Mobile homes	21	0.05
4	Condos	60	0.05
7	Vacant –to be developed	0	0.4
8	Multifamily	60	0.05
TH 101	Townhomes	91	0.025
94	Road Right-of-Ways	50	0.08
	Open water	100	n/a
All others	Commercial, etc.	50	0.07

1.6 Precipitation

Rainfall used in the screening tool is based on the SFWMD 3-day 25-year storm, but can be modified for any rainfall event using the accumulated rainfall table obtained from NOAA Atlas 14 Point Precipitation Frequency Estimates (https://hdsc.nws.noaa.gov/hdsc/pfds/pfds_map_cont.html). **Error! Reference source not found.** shows the 3-day 25-year rainfall map based on the NOAA Atlas 14 dataset for the whole state. **Error! Reference source not found.** to **Error! Reference source not found.** rainfall 1-day 100-year, 1-day 10-year, and 1-day 5-year storm event scenarios, in inches.

(Source Data: NOAA Atlas 14 Database)

1.7 Open Space

Open space is defined as areas that are exempted from development. Generally, this means one or more of the following qualifiers exist:

1. Land that is valuable for recreation, forestry, fishing, or conservation of wildlife or natural resources
2. Land that is a prime natural feature of the state's landscape, such as a shoreline or ridgeline
3. Land that is habitat for native plant or animal species listed as threatened, endangered, or of special concern
4. Land that is a relatively undisturbed example of an uncommon native ecological community
5. Land that is important for enhancing and conserving the water quality of lakes, rivers, and coastal water
6. Land that is valuable for preserving local agricultural heritage
7. Proximity to urban areas or areas with open space deficiencies and underserved populations
8. Vulnerability of land to development
9. Stewardship needs and management constraints
10. Preservation of forest land and water bodies that naturally absorb significant amounts of carbon dioxide

Permanent protection of sensitive areas can provide critical water quality protection and can be achieved through partnerships with landowners, municipalities, land trusts and state agencies. There is limited land in the study area that has been protected via acquisition by federal, state or local agencies, has conservation easements or is designated as wetlands or areas of critical concern. Agricultural land and other land cover will come from the land cover map (in Section 1.5). Added to this will be the water bodies discussed in Section 1.9, which serve a related condition to open space.

1.8 Impervious Areas

Impervious areas do not permit the infiltration of rainfall to groundwater, and because the water cannot infiltrate, it runs off faster. Faster runoff means that flows to water bodies and storm sewers occur faster and with higher peaks. The result is a disruption of the natural and potentially the planned hydrology. Impervious areas include pavement, buildings, and other areas that reduce runoff capacity. In other words, developed areas have much higher imperviousness than open spaces that are natural or agricultural.

The NLCD provides nationwide data on land cover and land cover change at a 30-m resolution with a 16-class legend based on a modified Anderson Level II classification system. Systematically aligned over time, the database offers the ability to understand both current and historical land cover and land cover change to enable assessment of trends. Using the NLCD 2016 dataset, a layer was created by using only three categories out of the 13 to identify impervious areas such as primary roads in urban areas, secondary roads in urban areas, and tertiary roads in urban areas. The new layer was then converted to match the 3-meter spatial resolution from the DEM and the standard State Plane Coordinate system. **Error! Reference source not found.** shows the impervious areas derived from the NLCD 2016 as updated by the future land use map.

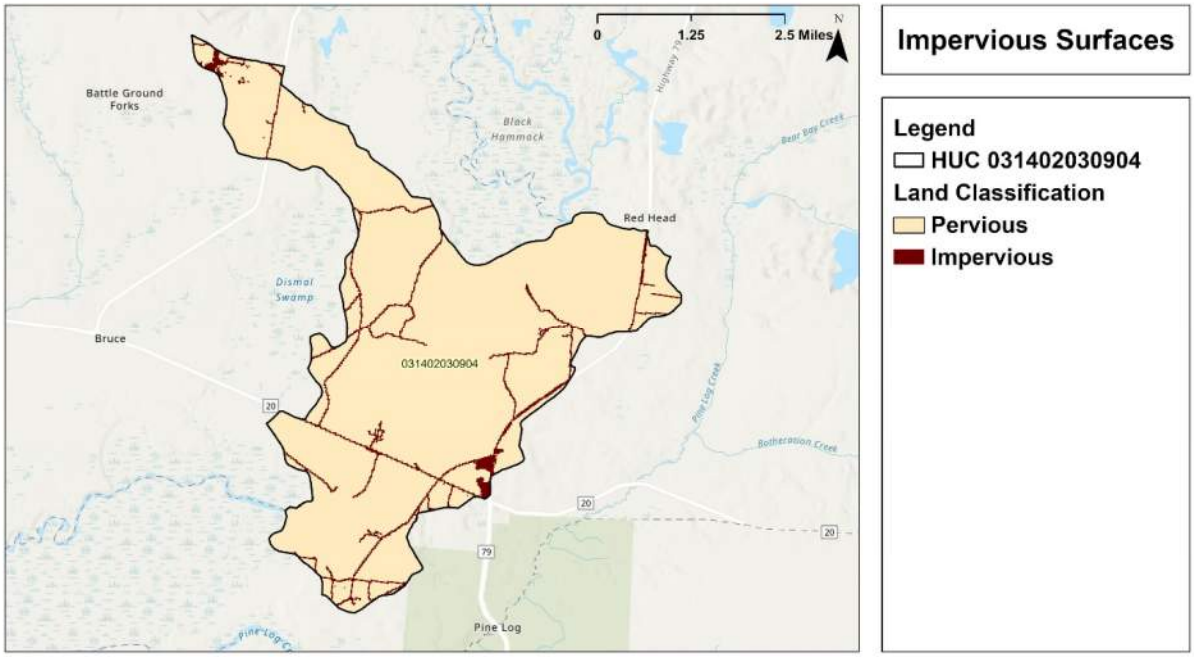

Figure 25. Impervious area map for the HUC 031402030904 sub-watershed, processed by FAU. (Source Data: NLCD, 2016)

1.9 Water bodies

Water bodies were defined in the statewide land use land cover dataset to set soil water holding capacity to zero in model simulations (**Error! Reference source not found.**). Note that tiny water bodies may be missing from the maps. Soils were discussed previously in Section 1.4.

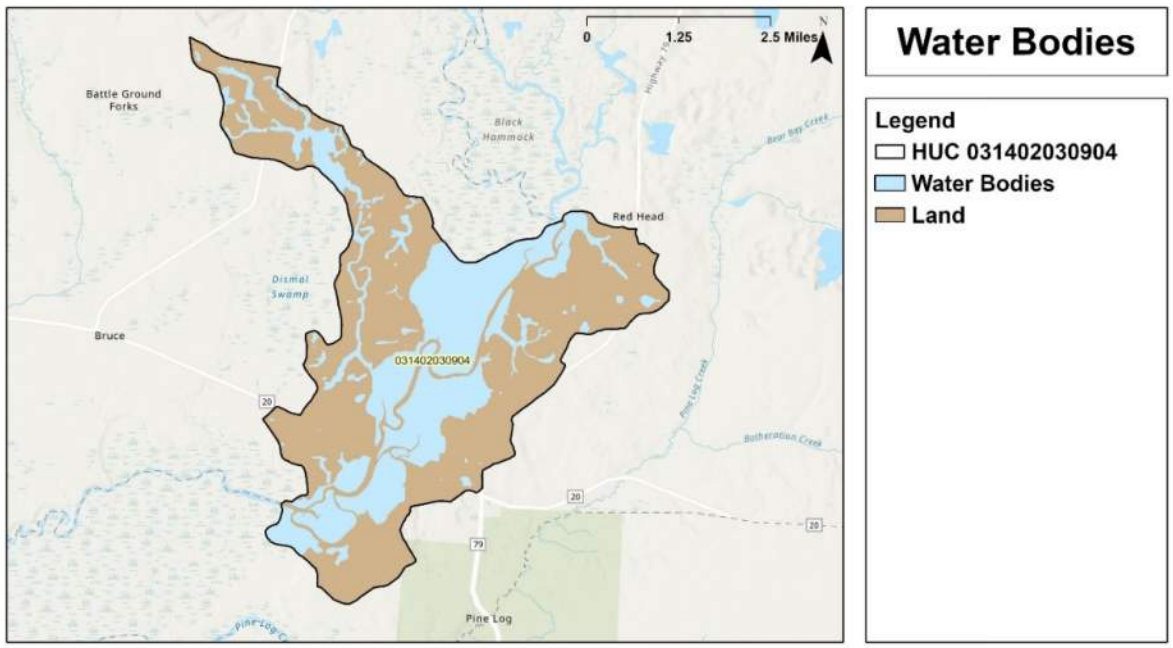

Figure 26. Water bodies map for the HUC 031402030904 sub-watershed, processed by FAU. (Source Data: USEPA – National Hydrographic Dataset (NHD))

1.10 Natural Resources

Understanding the study area's natural resources is critical to identifying potential sources of water quality degradation and areas to designate for conservation, protection, and restoration. One possible goal of watershed master planning is to protect terrestrial wildlife, aquatic habitat, and buffer zones. USGS maintains important sources of information on physical and geographical features as well as soil and mineral resources, surface and ground water resources, topographic maps, and water quality monitoring data. The USDA's Natural Resources Inventory (NRI) (www.nrcs.usda.gov/technical/NRI) is a survey of information on natural resources on non-federal land in the United States that captures data on land cover and land use, soil erosion, prime farmland soils, wetlands, habitat diversity, erosion, conservation practices, and related items. Since 2001, the NRI has been updated continually with annual releases of NRI data from all 50 states. The information provided can be used for addressing agricultural and environmental issues down to the county or cataloging unit level. Therefore, this data can be used to determine erosion and site-specific soil characteristics for certain land uses such as croplands, pasturelands, forestlands, etc., but the data is typically provided as inventories, not GIS layers.

1.11 Demographics

Demographics data is important for determining several key indicators for watershed master planning such as the ability to pay for improvements, social justice issues, land acquisition costs, property/land use, and communication strategies. The US Census has databases at the census tract level. Based on the census data for the study area, **Error! Reference source not found.** outlines population and racial composition demographics.

Table 5. Demographics and Housing Characteristics of Cities and Towns in Walton County.

Demographic Parameter	**Miramar Beach**	**Freeport**	**DeFuniak Springs, City**	**Paxton**	**Rosemary Beach**	**Santa Rosa Beach***	**Walton County**
Type	CDP**	City	City - County Seat	Town	Unincorporated community		County
Area in square miles	7.02	18.94	13.95	4.01	17,021	68,722	1,038.29

*It includes the communities of Point Washington to the East and a 15-mile stretch of the Emerald Coast from the east side of Miramar Beach to the west side of Seagrove Beach and the beach communities along 30A, including Grayton Beach and Seaside.

** Census Designated Place

1.12 Stormwater Infrastructure Inventory

Local community stormwater systems consist of drainage ditches, storm sewers, retention ponds and other facilities constructed to store runoff or carry it to a receiving stream, lake, ocean, or other waterbody. Other man-made features include yards and swales that collect runoff and direct it to the sewers and ditches. When most of these systems were built, they were typically designed to handle the amount of water expected during a 10-year storm. Larger storms overload them, and the resulting backed-up sewers and overloaded ditches produce shallow flooding. Another urban drainage problem occurs in the areas protected by levees. Being in floodplains, they are flat and do not drain naturally, especially when a levee blocks the flow to the river. To drain these areas, channels have been built and pumps installed to mechanically move the water past the levee. Often, these man-made systems do not have the capacity to handle heavy rains or intense storms.

Another challenge with stormwater infrastructure is related to recordkeeping. It is not uncommon for stormwater data to be incomplete in most jurisdictions and completely lacking in others. Quality of data differs from jurisdiction to jurisdiction; some are in GIS formats, while others are paper maps or as-builts that represent the infrastructure at a macroscale level. The condition of the assets may be lacking, and the maintenance history may not be available either. Stormwater assets may have been installed with no records, especially in rural areas, farm fields, and private property.

Walton County passed Ordinance No. 2008-06 that prohibits unauthorized discharges into storm drains or ditch systems. In addition, the Public Works Division is currently running a continuous public awareness campaign aimed at encouraging the adoption of best management practices (BMPs) for managing stormwater runoff. This initiative targets both the business community and the residents of Walton County.

To address the issue of flooding, Walton County has implemented several measures along the years, such as:

- Drainage Systems: The county has invested in the development and maintenance of drainage systems, including ditches, canals, and retention ponds, to manage stormwater runoff and reduce flood risk.
- Floodplain Management: Walton County has adopted floodplain management regulations and participates in the National Flood Insurance Program (NFIP) to encourage responsible development in flood-prone areas.
- Elevation Standards: New construction projects within flood zones are required to adhere to specific elevation standards to minimize potential flood damage.

- Emergency Response: The county has established emergency response plans to assist residents during flood events, including evacuation procedures and the provision of emergency shelters.

Key stormwater assets for the HUC and Walton County are indicated in **Error! Reference source not found.** and **Error! Reference source not found.**, respectively. Stormwater structures and management processes in the county consist of stormwater outfall, water wells, weir, pollutant control boxes, inlets catch basins, pipes culverts, ditch conveyance swales, structures, pipes and open conveyance.

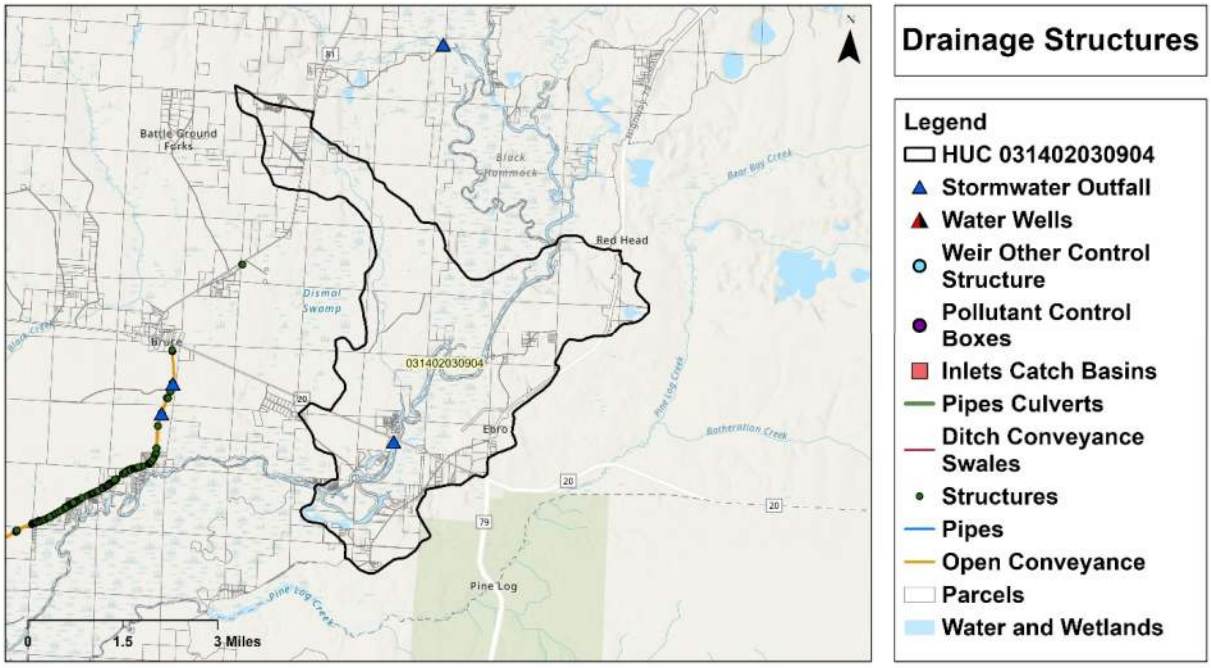

Figure 27. Stormwater Infrastructure for the HUC 031402030904. Processed by FAU.
(Source Data: Walton County Storm Asset Inventory and Stormwater Inventory)

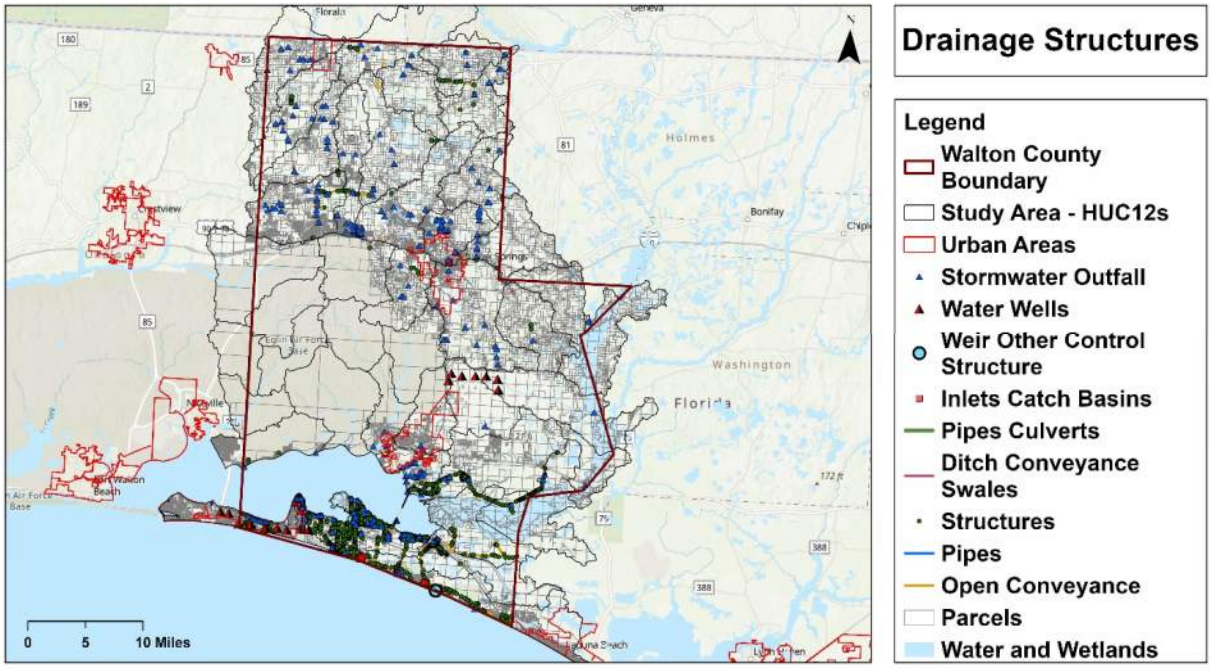

Figure 28.Stormwater Infrastructure for Walton County. Processed by FAU.
(Source Data: Walton County Storm Asset Inventory and Stormwater Inventory)

Although nature-based infrastructure might be installed, it is not certain. The stormwater system must maintain compliance with the stormwater regulations, which requires record-keeping, policy development, inspections and maintenance. The goals of such stormwater management may include:

- Best landscape practice;
- Control car washing contribution to pollution;
- Enforce the Stormwater Pollution Prevention Plan (SWPPP) by site evaluation, assessment, erosion and sediment controls, preventive maintenance, certification and inspection reporting for construction sites and city planning;
- Implement a hazardous material elimination system;
- Eliminate illicit dumping;
- Proactive and reactive catch basin inspections and maintenance;
- Street sweeping to control debris;
- Maintain swales to help prevent stormwater pollution flooding.

1.13 Data Gaps

FAU has developed comprehensive databases to address the information needed for the vulnerability assessment. These are included in **Error! Reference source not found.**. The data can be used to model the impacts of flood routing during the storm of interest. As a result, the modeling pieces (discussed in Chapter 2) will include the following:

- Flood response model results (Cascade 2001)
- Flood risk/hazard mapping
- Vulnerability assessments to identify areas of concern for future repetitive losses

There is only one data gap for the area – existing stormwater infrastructure records are incomplete. However, for the purposes of this plan, this data gap does not limit the findings as there are two scales: 1) the sub-watershed level and 2) community hotspots. A neighborhood level vulnerability assessment will require the local infrastructure inventory.

Table 6. List of datasets collected by FAU as of List of datasets collected by FAU for the project (12/20/2020)

Data Category	Dataset Name	Original Source	Spatial Coverage/ Resolution	Temporal Coverage/ Resolution	Link to the Dataset on our Server (physical location)	Dataset size and Format	Native or FAU Processed dataset

2.0 ASSESSMENT OF VULNERABLE AREAS

Defining flood risk due to compounding hydrographic influences is the central concern of this WMP. Modeling and assessment of vulnerability focused on the combination of a high-water table, heavy rains, and impervious conditions that can lead to localized nuisance flooding events. Through a previous survey with local officials, the number of days of continuous nuisance flooding that the public will tolerate before that flooding is considered destructive is about 4 days (E Science 2014).

For a large study area, small parts may actually be at risk. The point is to identify where further study might be needed. A screening tool accomplishes this goal applied to the sub-watershed scale to designate areas that are susceptible to periodic flooding events. Utilizing the information collected and analyzed in Chapters 1, analysis of flood vulnerability can be performed.

2.1 Historical and Existing Challenges

Walton County has faced various historical and existing challenges as well as natural hazards over the years. Some of these include:

- Hurricane and Tropical Storms: being situated along the Gulf Coast, Walton County is vulnerable to hurricanes and tropical storms, which can lead to damage to the built and natural environment, as well as poses risks to human and wild life.
- Coastal Erosion: The county's coastline is subject to erosion due to natural processes and human activities. Erosion can lead to the loss of beaches and threaten coastal structures and properties.
- Flooding: heavy rainfall, storm surges from hurricanes, and other factors can cause localized flooding, particularly in low-lying areas. Flood events can disrupt daily life, damage property, and impact transportation.
- Water Quality and Quantity: as in many coastal areas, managing water quality and maintaining an adequate water supply are ongoing challenges. Pollution from stormwater runoff and other sources can affect water quality, and groundwater resources need to be carefully managed to sustain the growing population.
- Wetland Loss: The county's wetlands face the threat of degradation and loss due to urban development and other human activities. Protecting these essential ecosystems is vital for maintaining biodiversity and mitigating flood risks.
- Urbanization and Development: Balancing the demand for development and growth with the preservation of natural habitats and resources is a persistent challenge. Unplanned

urbanization can lead to habitat destruction, increased runoff, and exacerbate flooding risks.

- Land Use and Zoning: Proper land use planning and zoning are essential to address issues related to population growth, infrastructure development, and natural hazard mitigation. Ensuring responsible development practices can help minimize risks.
- Invasive Species: Like many regions, Walton County faces the threat of invasive plant and animal species. These invasive species can disrupt local ecosystems, negatively impacting native flora and fauna.
- Sea-Level Rise: With rising sea levels due to climate change, coastal communities like Walton County's coastal areas are at greater risk of inundation and storm surges during extreme weather events.

The fast growth of the population and urban development in the coastal areas of the county exacerbates effort to protect open space for land percolation of water. While regulations are in place to reduce the influx of stormwater, the challenges will continue with development.

2.1.1 Existing Management Efforts in the Watershed

The county is under Northwest Florida Management District (NWFMWD) jurisdiction, which covers the Florida Panhandle region. The NWFMWD is responsible for managing and protecting water resources in its designated regions, which includes issues related to water supply, water quality, flood control, and natural resource conservation. Local governments have local stormwater utility infrastructure and planning/policy tools to reduce future flood potential. Most of the major projects to date have been focused on addressing water quality issues and flooding due to extreme rainfall.

2.1.2 Critical Target Areas Identification

By modeling the HUC 031402030904 sub-watershed flood response to a series of rainfall events and sea levels (plus king tides), and further classifying flood risk as the probability of inundation, it is possible to identify critical target areas. These areas are particularly vulnerable to flooding and are subject to further study through a scaled-down modeling approach. The screening tool is first applied at the greater watershed level to provide an initial risk assessment focused on the hydrologic response to a rainfall event given the unique characteristics and features of the sub-watershed or study area. The process is discussed later in Section 2.2 with results presented in Section 2.4.

2.1.3 Potential Preservation Areas

Walton County boasts several areas with high biodiversity value. These areas include the unique coastal dune lakes, which support diverse ecosystems and contribute to water quality along the coast. Wetlands are crucial habitats that provide refuge for a variety of plant and animal species while acting as natural water filters. State parks like Topsail Hill Preserve and Grayton Beach State Park are valuable conservation areas with diverse coastal ecosystems. Additionally, preserving the Choctawhatchee River Basin is essential for the biodiversity of the region.

2.2 Vulnerability Maps

2.2.1 Screening Tool

The screening tool utilizes topographic data from various sources (Section 1.1), water table elevations (Section 1.2) and surface water gauges (Section 1.3) downloaded from the NWFWMD DBHYDRO website, tidal information for coastal areas obtained from the NOAA Current & Tides website (Section 1.3), soil maps obtained from the USDA (Section 1.4), and another key dataset as described previously in Chapter 1. The design storms are discussed in Section 1.6. The reason this is critical is that to do any modeling (as required by the CRS program), a screening tool should be used to identify regions with a high risk of inundation based on multiple collected datasets and hydrological models. Figure 29 shows how the GIS layers interface in the tool and how they are combined for spatial analysis.

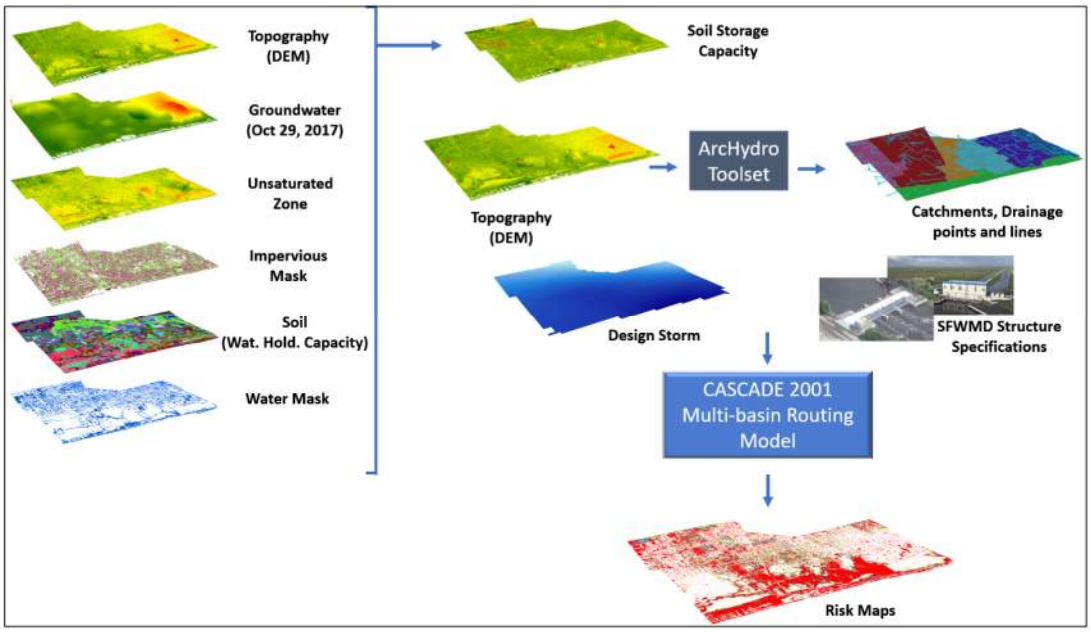

Figure 29. Screening tool methodology for creating flood risk maps.

The model chosen for this screening tool is Cascade 2001, which is a multi-basin hydrologic/hydraulic routing model developed by the SFWMD. The model permits the investigator to run different storm events to determine flooding scenarios. The boundaries are critical for basin studies and must be chosen carefully. The following data layers collected in the prior section are processed to develop the input files for Cascade 2001:

- Topography
- Soils
- Development intensity
- Groundwater elevations
- Surface water/Outlet locations

The software creates a glass box where water rises to a certain level and then decreases. Running the simulation requires defining the basin (HUC or sub-HUC) and input of the following data:

- Area
- Portion of area above a given elevation
- Initial groundwater stage
- Longest travel time for the runoff to reach the most distance point of discharge
- Ground storage as estimated from the USDA gridded National Soil Survey Geographic Database (gNATSGO)

  Ground storage ≈ (Water holding capacity) × (Surface elevation – GW elevation)
  = 2 × (AWS for a soil layer of 0-150 cm) / 150cm × (Surface elevation – GW elevation)

- Available water storage (AWS) for a soil layer of 0-150 cm
- Average amount of precipitation that can be stored in the soil layer

The output from the model is an elevation surface that can be used to develop a flood map for the study area (**Error! Reference source not found.**), which shows the spatial distribution of probabilities of flooding during the modeled 1-day 100-year storm event.

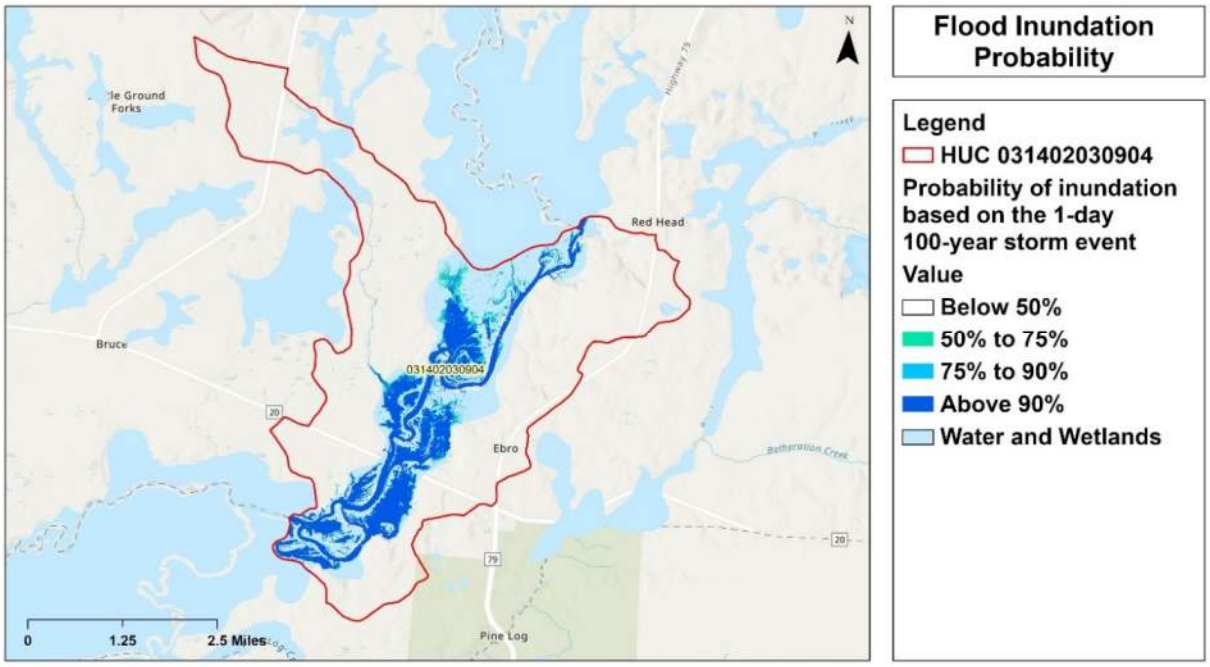

Figure 30. Probability of flood risk map during the modeled 1-day 100-year storm event for the HUC 031402030904, processed by FAU.

2.2.2 Identification of Vulnerable Areas

Given these assumptions and the Cascade 2001 outputs, the goal of this methodology is to produce a spatially-temporally quantified understanding of nuisance-destructive flood potential in the study area given observed values. Risk is a function of compounding geo-hydrological features, namely, surface water, groundwater, topography, build-out, and time of year. A GIS-based algorithm and spatial interpolation generated layers of the greatest observable hydrographic surfaces. These outputs were then compared with high resolution topographic LiDAR data to develop digital elevation models that reflect the observed risk landscape. These models can then be combined into Cascade 2001 to produce vector and volume information, in combination with soils, vegetation and impervious surfaces, allowing the observed model outputs to be extrapolated into a more predictive context.

To evaluate flood vulnerability at this scale, the analysis starts with a binary flooding surface (0 = below 50% chance of flooding; 1 = above 50% flooding) based on output from the screening tool for a specified design storm. Next, attributes of that raster based on "VALUE = 1" query are extracted using *Extract by Attributes* tool. Then the *Batch Project* tool was used to map critical facilities data to the common coordinate system (NAD83 UTM Zone 17N), unit = meters. Then a field was added using *Add Field* for [PriorityTier] = assigned Tier #1-4 value from the DOR codes

and [Area_sqmeter]. The critical facilities layers were then merged into a single layer to calculate the polygon geometry for [Area_sqmeter] using the *Merge* tool. Next, *Zonal Statistics as Table* is used to calculate the SUM of flooded values ("VALUE = 1") within each critical parcel. Output table has fields for SUM (i.e., total # of flooded pixels per critical parcel) and AREA in map units of square meters (since each pixel in the flooding surface has a cell size of 3-meters by 3-meters, each area is equal to the SUM value multiplied by 9 m^2). Using the *Join Field* tool, the SUM and AREA fields are joined to the merged critical facilities layer based on a key attribute, first renaming these fields for clarity (e.g., AREA_FLOODED_3d25y). Once all field data is included, the next step involves using *Export Table* to export the dataset as a CSV file. Note that non-flooded parcels have zero flooded area, so they receive a <Null> value from the zonal statistics tool. To replace null values with zeros, we use *Calculate Field* in the attribute table along with the following Python expression (replacing the respective field name): "0 if !AREA_FLOODED_3d25y! is None else !AREA_FLOODED_3d25y!". Next, the CSV file is saved as an Excel Workbook (.xlsx). The Range is converted to an Excel table, and the columns are rearranged in the desired order. Finally, the "percent-flooded" columns are calculated as follows:

- PCT_FLOODED_3d25y = ([@[AREA_FLOODED_3d25y]]/[@[TotalArea_sqmeter]])*100
- PCT_FLOODED_1d100y = ([@[AREA_FLOODED_1d100y]]/[@[TotalArea_sqmeter]])*100

After this calculation, the table is sorted to show the higher priority tiers and higher percent-flooded values first. To reduce the number of critical facilities shown in the final table, a filter was created to show only critical facilities with 10% or more flooded area in the parcel during both storm events. Records with duplicate parcel ID numbers were removed from the table. The results of this procedure are discussed in Section 2.5 of this document.

With respect to dams and levees, for purposes of the NFIP, FEMA only recognizes systems that meet, and continue to meet, minimum design, operation, and maintenance standards that are consistent with comprehensive floodplain management criteria. The Code of Federal Regulations, Title 44, Section 65.10 (44 CFR 65.10) describes the information needed for FEMA to determine if a levee system reduces the risk from the 1% annual chance flood. FEMA has accredited levees and Provisionally Accredited Levees (that have a specified timeframe to obtain the necessary data to confirm the levee's certification status). If a levee system no longer meets Section 65.10, FEMA will de-accredit the levee system and issue an effective FIRM showing the levee-impacted area as a SFHA. FEMA coordinates its programs with USACE, who may inspect, maintain, and repair levee systems. USACE has authority under Public Law 84-99 to supplement local efforts to repair flood control projects that are damaged by floods. Like FEMA, USACE provides a program to allow public sponsors or operators to address levee system maintenance deficiencies. Failure to do so within the required timeframe results in the levee system being placed in an inactive status in

the USACE Rehabilitation and Inspection Program. Levee systems in an inactive status are not eligible for rehabilitation assistance under Public Law 84-99. There are no levees/dams listed in the sub-watershed study area.

2.3 Future Challenges of Sea Level Rise and Climate Change

Global observations from satellites and long-term data collection have made it possible to document and analyze patterns in the Earth's climate. Scientific analysis of the impact of these changes has helped to improve the understanding of future flood hazard driving forces and long-term impacts on human activities and watershed master planning (http://www.research.noaa.gov/climate/t_observing.html). Examples of impacts are rising global average air and ocean temperatures, increased and earlier snow and ice melt, shorter subtropical rainy seasons, shifted seasons, sea level rise and greater variations in temperature and precipitation (IPCC, 2013; Freas et al., 2008; Marshall et al., 2004; Bloetscher et al., 2010). Marshall et al. (2004) specifically focused on the Florida peninsula to predict changes in rainfall and warmer temperatures but interspersed lower low temperatures due to the potential loss of wetlands.

Future changes in climate will add to the existing impacts, at a time when the population of the state is expected to nearly double by 2030. Additional research and high-resolution climate modeling for the Florida peninsula and local jurisdictions is needed to help guide long-term plans like WMPs. Rainfall appears to be decreasing and temperatures rising (see **Error! Reference source not found.**).

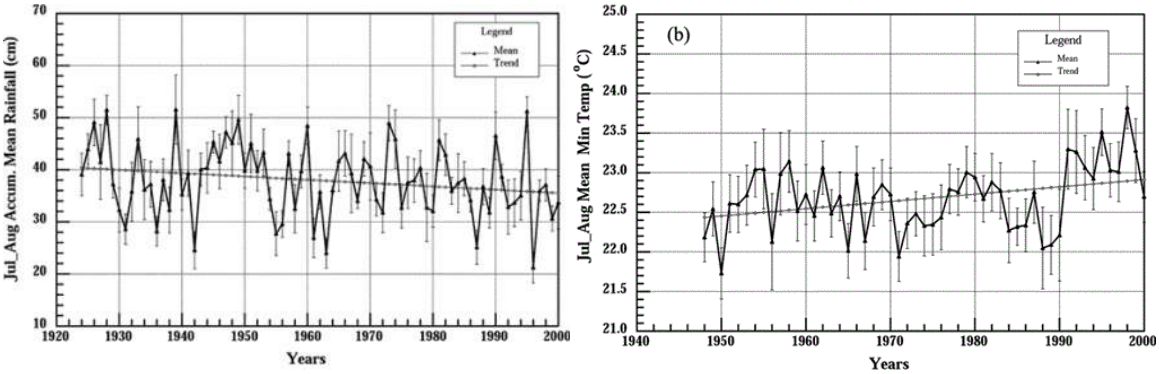

Figure 31. Change in average rainfall and change in average temp 1924 to 2000.
Note the reversed trend, which means groundwater input variability is lessened.
(Source: Marshall et al., 2004)

Climate change is likely to: 1) threaten the integrity and availability of fresh water supplies and 2) increase the risk of flooding, not only in the low-lying coastal areas, but also in the interior flood plains. Other issues include a) saltwater intrusion, which may be intensified by sea level rise, b) prolonged droughts that will contribute to water supply shortages and wildfires, and c) heavier

rains during the rainy season and higher hurricane storm surge, which may increase the risk due to flooding. More frequent and damaging floods are likely to become an ever-increasing problem as sea level continues to rise because of: a) increasing groundwater table elevations and surface water gage heights, b) reduced groundwater seepage through the aquifer to the ocean, c) increasingly compromised stormwater drainage systems, and d) more frequent inundation of barrier islands and coastal areas.

NOAA and IPCC (2013) predictions suggest that by 2100, global temperatures will be on the order of 2-3°C (3-5°F) higher and sea levels will rise by up to 3 feet. Accompanying these drivers are potential changes in storm frequency and intensity, desertification, population migration, ocean acidification and coastal flooding (IPCC, 2007), exacerbated by the land cover and land use changes, which are substantially impacted by the fluxes, timing and quality of precipitation (Adrians et al., 2003; Scanlon et al., 2005; Marshall et al., 2004; Salmun and Molod, 2006), and leading to changes in the timing of peak flows and volumes (Richey and Costa-Cabral, 2006).

The results of these climatic changes are likely to: 1) threaten the integrity and availability of fresh water supplies and 2) increase the risk of flooding, not only in the low-lying coastal areas, but also in the interior flood plains. Other issues include a) saltwater intrusion, which may be intensified by sea level rise, b) prolonged droughts that will contribute to water supply shortages and wildfires, and c) heavier rains during the rainy season and higher hurricane storm surge, which may increase the risk due to flooding. More frequent and damaging floods are likely to become an ever-increasing problem as sea level continues to rise because of: a) increasing groundwater table elevations and surface water gage heights, b) reduced groundwater seepage through the aquifer to the ocean, c) increasingly An outcome of these climatic patterns is that during the past 140 years, an increase in sea levels has been observed (Bloetscher, 2012), a worrying pattern since sea level rise is a permanent phenomenon, that can be catastrophic to low lying areas in the long-term. The question is how much and how soon? Various studies (Bindoff et al., 2007; Domingues et al., 2008; Edwards, 2007; Gregory, 2008; Vermeer and Rahmstorf, 2009; Jevrejeva, Moore and Grinsted, 2010; Bloetscher, 2010, 2011; IPCC, 2007; Heimlich et al., 2009) indicate large uncertainty in projections of sea level rise by 2100. Gregory et al. (2012) note that during the last two decades, the global rate of sea level rise has been larger than the 20th-century time-mean, and Church et al. (2011) suggested that the cause was increased rates of thermal expansion, glacier mass loss, and ice discharge from icesheets. Gregory et al. (2012) suggested that there may also be increasing contributions to global sea level rise from the effects of groundwater depletion, reservoir impoundment, and loss of storage capacity in surface waters due to siltation. Measurements of Florida's east coast (Maul, 2008) show an average rate of sea level rise of 2.27 ± 0.04 mm per year from 1915 to 1992 based on tide gauge readings. Analyzing the tidal gauge readings for Florida shows that:

1. Florida average sea level rise is 2.10 ± 0.49 mm/yr

2. All but one location is within the 95% confidence limit range (the exception is Panama City where there is evidence of submergence and other land-based issues)
3. None of the Florida sea level rise rates differ statistically
4. Average global sea level rise for 1920-2000 was 2.0 mm/yr – within 95% confidence limit for Florida locations

From 1929 to 1992, over eight inches of sea, with another 6 inches added since 1992, which is already having significant impacts on coastal communities where population growth has increased the need for improved flood management strategies (Bloetscher, 2008; Parkinson, 2010; Zhang et al., 2011, 2011a; NFIP, 2011; Schmidt et al., 2011; Warner et al., 2012).

As a result, the SFRCCC (2015) adopted USACE's methodology to derive scenarios of sea level change intermediate to high rates of sea level rise for years 2030 (3" to 7") and 2060 (9" to 24") as the consensus projection to guide future planning. The path keeps increasing – now 14 inches since 1929 (**Error! Reference source not found.**) caused by thermal expansion of the ocean and melting ice caps (Jevrejeva et al., 2010; Vermeer and Rahmstorf, 2009). Sea level rise is a major concern in Florida, including Walton County, since the majority of the state's population live on the coast, involving most major commercial, residential, and economic enterprises. **Error! Reference source not found.** demonstrate the estimated sea level change for Panama City, considering the predictions of NOAA 2017. For NOAA high scenario SLR change scenario, the estimated level change is higher than 8 ft., while for the intermediate and low scenarios are about 3.9 feet and 1.7 feet respectively.

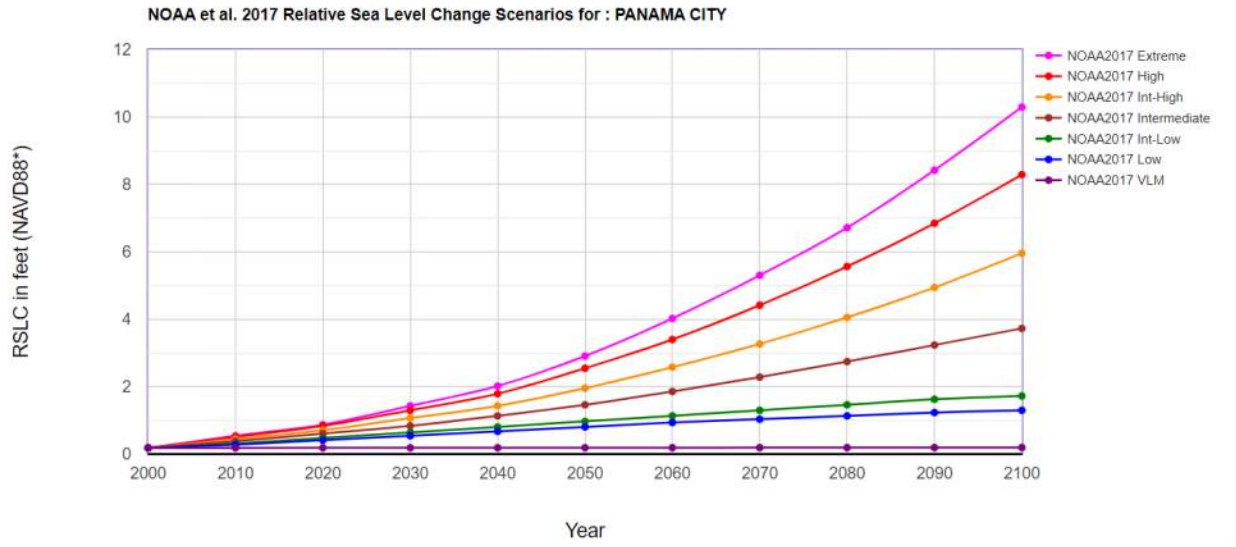

Figure 32. Relative Sea Level Change Scenarios for gauge 8729108, Panama City, FL. (Source: NOAA, 2017 available at https://cwbi-app.sec.usace.army.mil/rccslc/slcc_calc.html)

NOAA (2017) outlines five scenarios for sea level rise. The NFIP proposes the use of the intermediate high projection, which is 1.2 meters or 4 ft globally from current sea level elevations (**Error! Reference source not found.**).

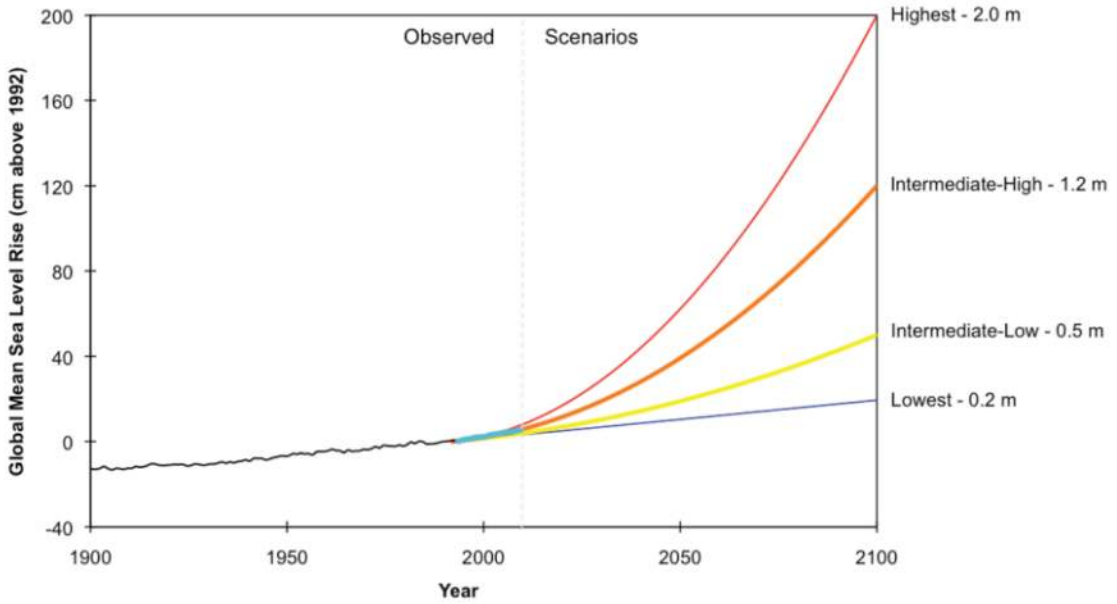

Figure 33. Graphic of global sea level rise projections from NOAA (2017).
(Source: NOAA, 2017 available at https://tidesandcurrents.noaa.gov/publications/techrpt83_Global_and_Regional_SLR_Scenarios_for_the_US_final.pdf)

As sea level rises, access to roads, bridges, rail, and transit could be at risk of flooding, causing the effects of sea level rise to spread indirectly throughout the entire transportation network, affecting the overall system performance. For example, the flooding of a critical road or facility access can cause a shifting of traffic flow causing congested conditions in other roadways that are not actually flooded. Since the roadway network would be unable to carry the traffic demand, the system would experience operational failure; as a result, causing travel times and delays. Moreover, the inundation of a critical access could cause transportation connectivity problems to essential infrastructure like ports or airports. Transportation infrastructure relies on the effectiveness of flood control and stormwater drainage systems for the transportation corridors. Road integrity relies on adequate drainage. The increased risk of severe flooding in Florida's low-lying terrain can adversely affect transportation infrastructure along the coastline; roads can be inundated, and roadway beds can be damaged. Sea level rise will cause increased water table levels (FDOT, 2012), as regional water tables cannot exist naturally below mean high tide (2 feet in Florida). Adding 3 feet of sea level rise on top of groundwater would compound the risk of flooding in low-lying areas. Road bases below 5 feet NVGD would become saturated under this scenario, likely causing premature base failure. As soil storage capacity is diminished due to rising

groundwater elevations associated with sea level rise, the potential for more frequently flooded roadways would likely damage pavements (FDOT, 2012). Hence sea level rise must be accounted for in WMPs in coastal areas. To allow flexibility in the analysis due to the range of increases within the different time periods, an approach that uses incremental increases of 1, 2, and 3 feet of sea level rise is suggested for modeling. The increments can work as threshold values in planning considerations in terms of allowing planners the ability to know ahead of time where the next set of vulnerable areas will be, to allow for a proactive response approach that can be matched to the observed future rates. Sea level rise is a major concern since nearly half the US population lives within 50 miles of the coast, involving most major commercial, residential, and economic enterprises. The effects of 5 ft sea level rise, King tide, and 1-day 100-year storm event are shown in **Error! Reference source not found.**.

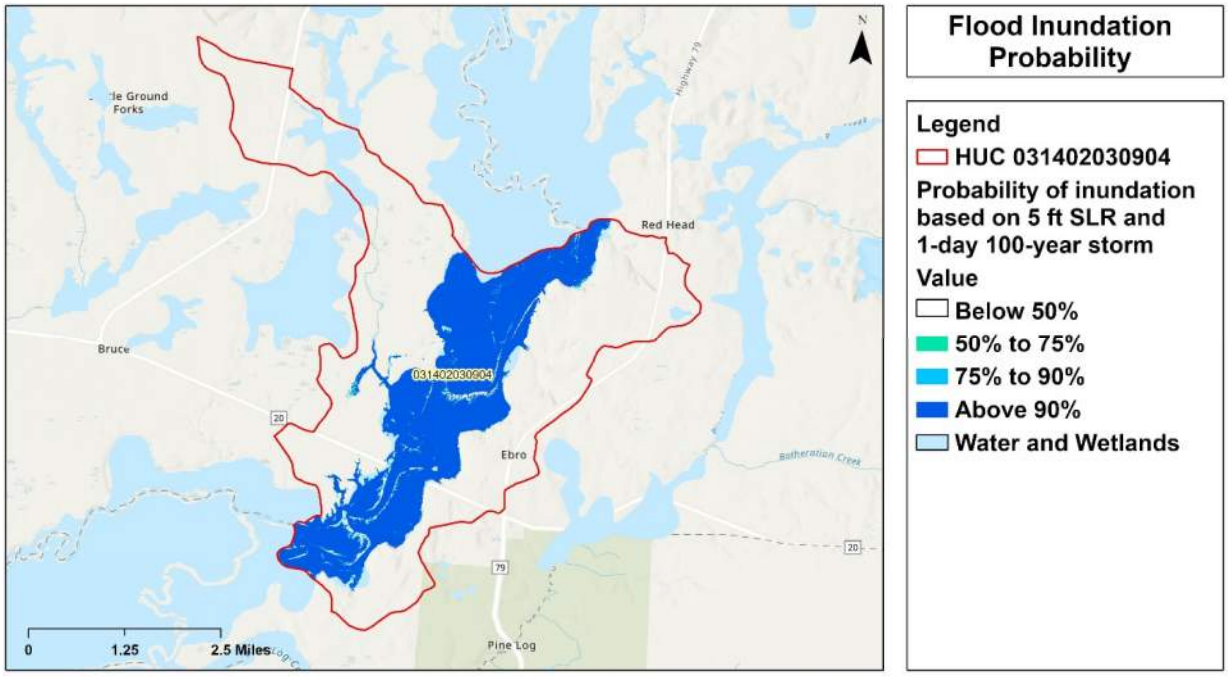

Figure 34. Flood Inundation Probability for a Sea level rise of 5 ft + 1-day 100-year storm event for HUC 031402030904 sub-watershed.
Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations. Dark blue is area under 5 ft NAVD

2.4 Modeling Results

Error! Reference source not found. to **Error! Reference source not found.** are a series of maps that depict risk of flooding in the basin based on the following scenarios:

1. **3-day 25-year storm event**. Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 35)
2. **1-day 100-year storm event**. Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 36)
3. **1-day 10-year storm event.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 37)
4. **1-day 5-year storm event.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 38)
5. **Sea level rise of 1 ft + 3-day 25-year storm** (only coastal area and GW affected – GW layer rises 1 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 39)
6. **Sea level rise of 1 ft + 1-day 100-year storm** (only coastal area and GW affected – GW layer rises 1 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations storm (Figure 40)
7. **Sea level rise of 1 ft + 1-day 10-year storm** (only coastal area and GW affected – GW layer rises 1 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 41)
8. **Sea level rise of 1 ft + 1-day 5-year storm** (only coastal area and GW affected – GW layer rises 1 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 42)
9. **Sea level rise of 2 ft + 3-day 25-year storm** (only coastal area and GW affected – GW layer rises 2 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 43)
10. **Sea level rise of 2 ft + 1-day 100-year storm** (only coastal area and GW affected – GW layer rises 2 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 44)
11. **Sea level rise of 2 ft + 1-day 10-year storm** (only coastal area and GW affected – GW layer rises 2 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 45)
12. **Sea level rise of 2 ft + 1-day 5-year storm** (only coastal area and GW affected – GW layer rises 2 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 46)
13. **Sea level rise of 3 ft + 3-day 25-year storm** (only coastal area and GW affected – GW layer rises 3 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 47)
14. **Sea level rise of 3 ft + 1-day 100-year storm** (only coastal area and GW affected – GW layer rises 3 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 48)

15. **Sea level rise of 3 ft + 1-day 10-year storm** (only coastal area and GW affected – GW layer rises 3 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 49)
16. **Sea level rise of 3 ft + 1-day 5-year storm** (only coastal area and GW affected – GW layer rises 3 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 50)
17. **Sea level rise of 4 ft + 3-day 25-year storm** (only coastal area and GW affected – GW layer rises 4 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 51)
18. **Sea level rise of 4 ft + 1-day 100-year storm** (only coastal area and GW affected – GW layer rises 4 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 52)
19. **Sea level rise of 4 ft + 1-day 10-year storm** (only coastal area and GW affected – GW layer rises 4 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 53)
20. **Sea level rise of 4 ft + 1-day 5-year storm** (only coastal area and GW affected – GW layer rises 4 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 54)
21. **Sea level rise of 5 ft + 3-day 25-year storm** (only coastal area and GW affected – GW layer rises 5 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 55)
22. **Sea level rise of 5 ft + 1-day 100-year storm** (only coastal area and GW affected – GW layer rises 5 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 56)
23. **Sea level rise of 5 ft + 1-day 10-year storm** (only coastal area and GW affected – GW layer rises 5 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 57)
24. **Sea level rise of 5 ft + 1-day 5-year storm** (only coastal area and GW affected – GW layer rises 5 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 58)

In all scenarios, a great amount of flooding is noted at the river entrance to the HUC, following the flow path along with the wetland areas until the next HUC. As this basin connects to the ocean though Choctawhatchee River, SLR scenarios plays an important hole, implying a considered growth as the projected scenario of rising tides rises.

The design storm simulation determined that approximately 14.26% of the HUC total area or 2.47 mi^2 has a probability of inundation above 50% for a 3-day 25-year design storm. For comparison, approximately 14.82% of the HUC's total area, or 2.56 mi^2 would be expected to be inundated during a 1-day 100-year design storm. Approximately 13.35% of the HUC's total area,

or 2.31 mi², would be expected to be inundated during a 1-day 10-year design storm. Finally, approximately 17.97% of the HUC's total area, or 3.11 mi², would be expected to be inundated during the 1-day 5-year storm. **Error! Reference source not found.** compares the four storm events.

Table 7. HUC 031402030904 expected inundated area by storm event.

Storm Event	Area with probability of inundation below 50% (Sq Mi)	Area with probability of inundation above 50% (Sq Mi)	Area with probability of inundation below 50% (%)	Area with probability of inundation above 50% (%)
3-day 25-year	14.82	2.47	85.73%	14.26%
1-day 100-year	14.72	2.56	85.18%	14.82%
1-day 10-year	14.98	2.31	86.65%	13.35%
1-day 5-year	14.18	3.11	82.02%	17.97%

2.5 Risk and Vulnerability

The screening tool modeling exercise from the prior section identified areas within the communities that are vulnerable to flooding. Higher priority concerns should be those properties or assets that are considered essential and need to be kept in service during a flooding event. All other improvements are local. To help with prioritization, the following is suggested:

- Tier 1 - Critical facility protection (water/sewer utilities, public safety, hospitals, schools, power, shelters)
- Tier 2 - Essential facilities (groceries, pharmacies, roadways)
- Tier 3 - Economic centers (protecting jobs)
- Tier 4 - At risk communities
- Tier 5 - Other urban/suburban property
- Tier 6 - Agriculture/public property/vacant/undeveloped

Error! Reference source not found. outlines the priority of land use based on DOR land use codes from the property appraiser's office and assigns an associated priority level to each parcel. Note that for residential property, identifying at-risk communities (income, age, disability, health) requires a further drilldown to the neighborhood level (i.e. wealthy neighborhoods with few older,

poor health individuals would have a lower priority than at risk communities, which generally have lower value housing and denser development). In the latter case, more people are impacted, and those people have less ability to mitigate risk. Based on these priorities, the relative risk priority DOR land use codes were evaluated based on a scale of 1 to 6, where 1 is higher priority (more vulnerable) and 6 is the least priority (least vulnerable).

Table 8. Priority of Land Use based on (DOR) land use codes. Processed by FAU.

96	Sewage Disposal	6

97	Outdoor Recreational Or Parkland, Or High-Water Recharge Subject To Classified Use Assessment	6
98	Centrally Assessed	6
99	Other Non-Agricultural Acreage	6
100	Parcel With no Values	6
101	Parcels With no Values (ROW - avenues, highways, arterials)	2
102	Parcels With no Values (Water)	6
103	Parcels With no Values (Rail)	2

Having assigned the risk priority from 1 to 6 in the DOR codes and the percentage of the parcel that floods during the applicable design storm, properties that are more critical to the function of the community can be identified. The methodology is to first convert the DOR code priority tier to its inverse scale by the following equation:

Consequence of risk factor = 7 – DOR Code Priority Tier

The flood risk factor from the screening tool is interpreted based on flooding probability. We take all parcels in tiers #1-4 that have a greater than 50% chance of flooding during a particular design storm and calculate the percent of the parcel that would flood during that event. The percentage is converted to a 6-point scale termed as the Flood Risk Factor, shown in **Error! Reference source not found.**.

Table 9. Flood Risk Factor Classification.

Percent of Parcel Flooded	Flood Risk Factor
90-100%	6
80-89%	5
70-79%	4
60-69%	3
50-59%	2
<50%	1

The priority is further developed by assigning 75% of the importance to the consequence of flooding and 25% importance to flood risk, or three times the importance to the consequence of flooding to come up with a composite score as follows:

Flood Risk Factor × 25% + Consequence of Risk Factor × 75% = Composite Score

Example: 1 × 25% + 6 × 75% = 4.75

Those higher priority properties that received the higher composite score are where the mitigation strategies and financial resources should focus first.

2.5.1 Results

Error! Reference source not found. to **Error! Reference source not found.** depict the HUC 031402030904 sub-watershed priority of land uses showing the critical facilities that should receive priority. The first map (**Error! Reference source not found.**) exclusively displays critical facility parcels within the HUC without any flooding. The second map (Figure 60) overlays critical facilities onto the 1-day 100-year storm event scenario, while the third map (**Error! Reference source not found.**) represents the same overlay within the context of 5 feet of sea level rise (SLR) combined with the 1-day 100-year storm event. **Error! Reference source not found.** is a mosaic showing critical facilities overlaid in the 5 feet SLR + 1-day 100-year storm event for the whole county.

Additionally, **Error! Reference source not found.** and **Error! Reference source not found.** illustrate the composite score for the HUC, which is the result of the calculations explained above, pinpointing parcels that should be prioritized. It considers only parcels classified as 1 to 4 tiers, and within the 50% probability of inundation area. **Error! Reference source not found.** represents the calculation for composite score based on 1-day 100-year storm event, while **Error! Reference source not found.** shows the calculation for composite score for the same storm event, but including a 5 feet of Sea Level Rise scenario. **Error! Reference source not found.** shows the same area zoomed out.

Please note that the composite score results display outcomes exclusively for parcels within the flooding path area. Consequently, for parcels outside this flooding path, the composite results will be null. The composite score combines the flooding path area with the land use priority results to identify the most vulnerable areas deserving of priority.

2.5.2 Solutions

Chapter 5 of the Watershed Master Plan for Walton County describes a list of possible gray and green stormwater strategies to combat flooding that can be implemented as solutions for the county. The same solutions can also be applied at the HUC level, including HUC 031402030904. A summary of these flood mitigation strategies is listed in **Error! Reference source not found.**. For more detailed information, please see Chapter 5-5.3 (Solutions).

Table 10. List of possible gray and green stormwater strategies to combat flooding

Strategy Class	Implementation Strategy	Applications	Benefits	Cost	Barriers to Implementation
Green	Rainwater harvesting	Local, small scale, easily implemented in developed areas	Protects property, treats runoff	Under $5,000	Limited volume disposed of, so many are needed, maintenance
Gray	Pervious paving	Parking lots, patios, driveways, anything except paved roads due to traffic loading	Reduces roadway and parking lot flooding	$10-20/sf, requires bumpers and sub-base to maintain paver integrity	Must be maintained via vacuuming or the perviousness fades after 2-3 years
Green	Detention	Common for new development, but difficult to retrofit; limited to open areas	Removes water from streets, reduces flooding	$200K/ac	Land availability, maintenance of pond, discharge location Uses up land that could otherwise be developed
Gray	Exfiltration Trench	Any low-lying area where stormwater collects and the water table is more than 3 ft below the surface; densely developed areas where retention is not available, roadways	Excess water drains to aquifer, some treatment provided	$250/ft	Significant damage to roadways for installation, maintenance needed, clogging issues reduce benefits
Gray	Central sewer installation	All areas where there are septic tanks. Mostly a water quality issue	Public health benefit of reducing discharges to lawns, canals, and groundwater from septic tanks	$15,000 per household	Cost, assessments against property owners, property rights issues

Strategy Class	Implementation Strategy	Applications	Benefits	Cost	Barriers to Implementation
Green	Flood prone property acquisition	Regional agency - could be any low-lying areas	Removes flood prone areas from risk	$2K-$100K/ac depending on whether it is already developed	Difficult to implement if occupied, issues with willing sellers, cost, lack of funds for acquisition
Gray	Pump stations	Any low-lying area where stormwater collects, and there is a place to pump the excess stormwater to such as a canal; common for developed areas	Removes water from streets, reduces flooding	Start at $1.5 to 5 million each, number unclear without more study	NPDES permits, maintenance cost, land acquisition, discharge quality
Gray	Armored sewer systems	Any area where gravity sanitary sewers are installed	Keeps stormwater out of sanitary sewer system and reduces potential for disease spread from sewage overflows	$500/manhole	Limited expense beyond capital cost
Gray	Sea walls	Barrier islands and downtown coastal areas	Protects property	$1200/ft	Private property rights, neighbors
Policy	Changes in land use	Applicable universally	Achieves flood risk mitigation by adjusting permitted land use	Low but may incur private property rights conflicts and litigation	Private property rights conflicts and litigation
Gray	Roadway base protection	Low-lying areas, coastal communities	Protects roads and access routes	$1 million per lane-mile	Cost, adjacent properties become uninsurable
Policy	Enhanced elevation of buildings	Developers would implement this for new construction	Reduced flood risk	Varies	Potential issues with building structure or latticework, and existing homes that are not elevated

2.5.3 Impacted Adjustment Areas

In the evaluation of flood risk management strategies within the framework of the National Flood Insurance Program Community Rating System (CRS), the concept of impact adjustment plays a pivotal role in determining the extent to which CRS-credited activities or elements influence the vulnerability of a community's Special Flood Hazard Area (SFHA) and the structures located within it. It's important to note that while the usual results of impact adjustment are related to the SFHA area, in this specific analysis, it was used 1-day 100-year storm event inundation area performed by FAU instead.

In this context, the following table presents a breakdown of the impact adjustment calculations for a 1-day 100-year storm event inundation. The values are expressed in acres and depict the areas of interest as well as the deductions considered in the evaluation process.

The outcomes of these calculations provide valuable insights into the impact adjustment scenarios:

With ALL State Lands:

This scenario reflects the remaining inundation area after accounting for deductions A, B, and C. It represents the effect of CRS-credited activities without considering the influence of state lands in managing flood risks.

With NO State Lands:

In this case, the remaining inundation area is determined by considering all deductions, including state lands (both open space and not open space– see **Error! Reference source not found.**).

These calculations highlight the dynamic nature of impact adjustment within the CRS framework. By accurately gauging the influence of individual elements, the system ensures that credit allocations align closely with a community's efforts in flood risk mitigation.

Table 11. Impacted Adjustment Areas for HUC 031402030904. Processed by FAU.

AREAS	ACRES
HUC-12 Sub-watershed: 031402030904	11061.00
All of the 1-day 100-year storm event inundation	**1638.95**
Subtract	
A. Bodies of Water in 1-day 100-year inundation > 10 acres	1182.57
B. Federal Land in 1-day 100-year inundation > 10 acres	0.00
C. Reservation/Tribal Land in 1-day 100-year inundation > 10 acres	0
D. State Land in 1-day 100-year inundation > 10 acres that is open space	85.04
E. State Land in 1-day 100-year inundation > 10 acres that is NOT open space	19.13
The remainder is either:	
With ALL State Lands: All of the 1-day 100-year inundation minus (A+B+C) or	456.38
With NO State Lands: All of the 1-day 100-year inundation minus (A+B+C+D+E)	352.21

2.5.4 Repetitive Loss Property Map

A Repetitive Loss (RL) property is a building that has had two or more loss or damage due to a specific hazard, such as floods, hurricanes, or other natural disasters, over $1,000 each, paid by the National Flood Insurance Program (NFIP) within any ten-year period since 1978. There are more than 122,000 RL properties in the nationwide (FEMA, 2005).

These data are essential for assessing the vulnerability of certain areas to recurrent losses and for developing strategies to mitigate the risks. However, due to privacy concerns, the data cannot be openly shared with the public. For this reason, the data were converted into a hot spot analysis map. These maps, instead of identifying the specific location of the repetitive loss properties, highlight clusters of repetitive loss claims and areas where the probability of repetitive losses is higher than would be expected by random chance. In other words, it helps pinpoint locations that have a higher concentration of properties prone to repetitive losses. **Error! Reference source not found.** indicates the results from hot spot analysis in point data, showing aggregated counts, and raster data, showing the estimated probability of repetitive loss.

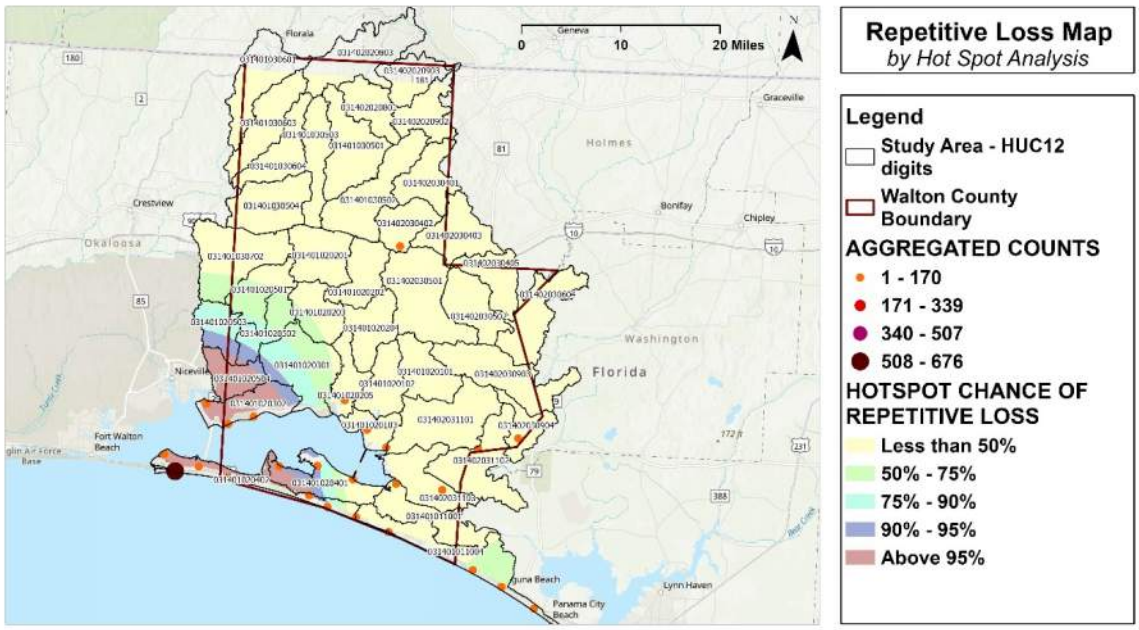

Figure 66. Repetitive Loss map for Walton County by Hot Spot Analysis. Processed by FAU. (Source Data: FEMA)

2.5.5 Priority Projects

The basin does not display a significant amount of developed land. While there are some parcels falling within tiers 2 to 5 of land use priority classifications within the basin, fortunately, only a few of them are within the flooding zone, despite the presence of substantial flooding in both 1-day 100-year storm events and 1-day 100-year + 5 feet sea level rise scenarios.

Consequently, when considering the composite score, it is notable that most of the results are null. There are as total 11 results for composite score within the basin. In the score range of 3-4, there are seven parcels, comprising three mobile homes and four roads (Us Hwy 20, Choctawhatchee River Rd, Cowford Rd, and Road Row). Lastly, there are four parcels with scores below 3, all of which are mobile homes. There is no parcel with a score 4-5 and 5-6 composite score, therefore the priorities within the basin are relatively low.

X.0 EXECUTIVE SUMMARY

The goal of the appendices to the watershed plan are to outline the issues associated with the individual HUC12s that contribute or impact the community's flood vulnerability and there for its flood protection efforts. Floodplain analysis includes developing a watershed model and identifying associated inundation polygons. It builds upon information generated from the watershed evaluation so that planning and management decisions can be formulated.

This appendix describes the issues and modeling associated with one of the HUC12s that affects Walton County. In developing the County-wide plan, this HUC 12 was analyzed so as to determine how it brings or removes floodwaters from the County. For the NFIP process the goal is to analyze all communities at the HUC12 level. From a community perspective the HUC12 is less useful to residents than a community-wide plan. Hence in all cases the HUC12 results were mosaicked into the community-wide plan. Details can be found in the HUC12 appendices, some of which were brought into the community plan.

To reduce redundancy, information of the plans, ordinances, policies and regulations were rolled up to the community-wide plan and will not be repeated in the appendices. Likewise, the community wide mapping was parced for HUC12 use.

1.0 WATERSHED CHARACTERIZATION

In this section, key aspects of the watershed are characterized. This is important for later being able to identify the most vulnerable areas and to mobilize resources to implement an action plan. Understanding the characteristics of the watershed involves gathering existing information and data sets from previous planning efforts. It is important to note that this step is iterative and ongoing as new data are generated and projects are implemented and monitored.

To assess the historical and current conditions of the study area, the following existing data sets that characterize the physical and natural features of the watershed were obtained for each HUC-12 sub-watershed in the study area:

- Topographic data (LiDAR)
- Relevant waterway locations
- Groundwater levels
- Soils data
- Land uses including vacant land, wetlands, impervious, etc.
- Precipitation records
- Catchment delineations for flood routing

In addition, the FEMA flood maps must be obtained, and the storm of interest must be identified for screening purposes (1-day 2-year, 5-year, and 100-year events as well as the 3-day 25-year storm event to achieve class 4 in the CRS Manual). In developed areas, many sources of data are already available – the key is putting the key datasets in a format that can queried for screening to identify the priority areas of the watershed. Table 6 is a summary of datasets available at cwr3.fau.edu that were used to construct this plan.

This watershed master plan is a drilldown of the larger Walton County TMDL region, which involves 42 HUC 12-digit sub-watersheds (**Error! Reference source not found.**). **Error! Reference source not found.** shows Walton County Drainage Network and the location of urban areas (cities and towns). In **Error! Reference source not found.**, the HUC-12 (031402031101) is highlighted among all the HUCs to help identifying its location. (Figure 3).

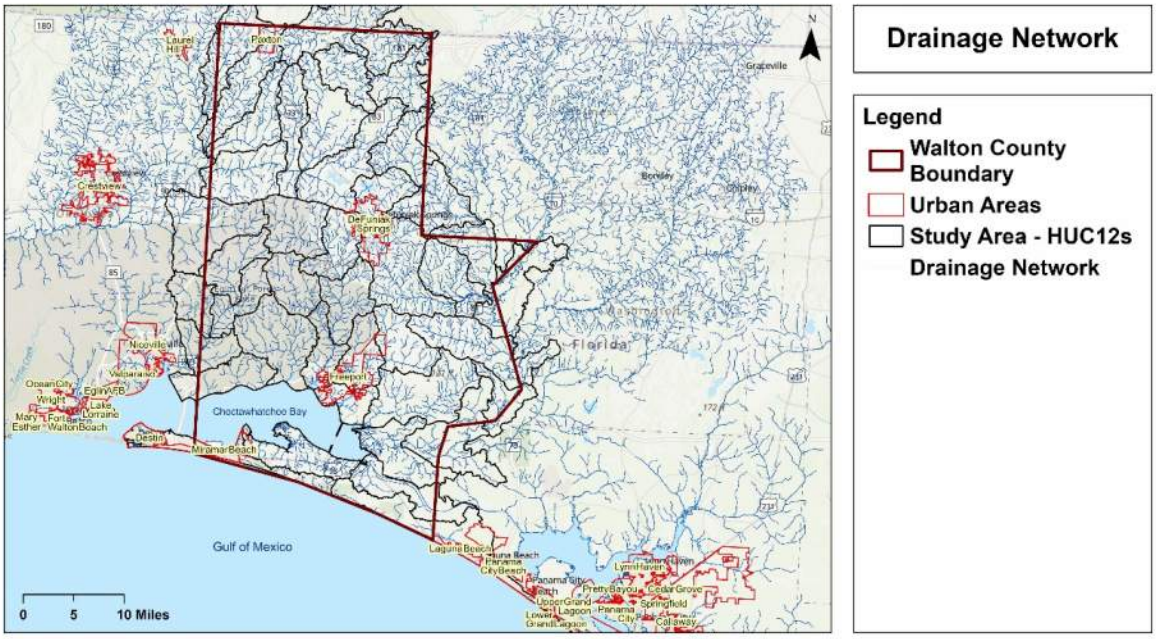

Figure 2. Walton County Drainage Network and urban areas (cities and towns), processed by FAU.

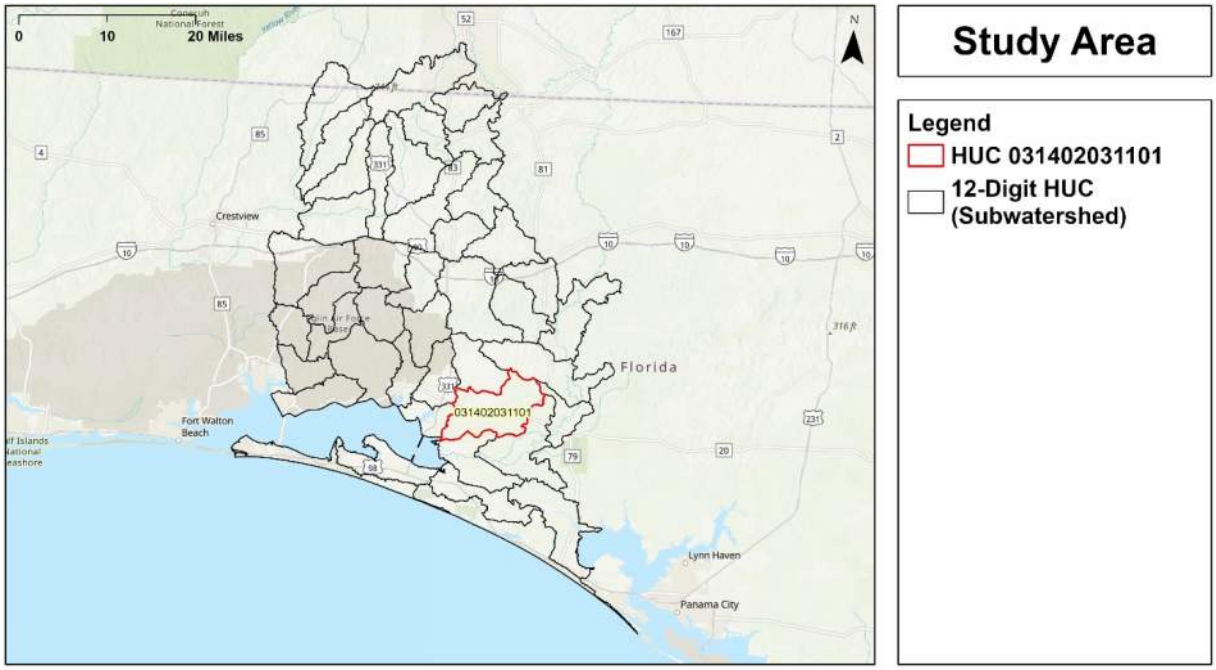

Figure 3. HUC 031402031101 sub-watershed location.

Located in the northwestern region of Florida, Walton County has 1,037.7 square miles of land and it is the 12th largest county in Florida by area, while also sits the highest point in the state,

with a height of 345 feet in its northern end. With a population of 75,305 residents according to the 2020 census and an estimate population in July of 2022 of 83,304, the county has experienced consistent growth within the past several years, driven by factors such as tourism, retirement migration, and regional population dynamics. The county was the residence for 55,043 people according to Census 2010, which leads to a percent change of 36.8% in 10 years, between 2010 and 2020, and a percentage change of 10.6% in two years, between 2020 and 2022 (United States Census Bureau).

The surge in population, particularly in the southern part of Walton County, has resulted in a corresponding expansion of infrastructure to cater to the growing needs. Essential facilities such as potable water systems, wastewater treatment plants, electrical utilities, roads, and schools have been developed to support this increasing population. However, the infrastructure expansion has brought about a significant change in the natural environment. Prior to the existing development, tropical cyclone impacts would be mitigated by natural barriers such as vegetated sand dunes, wetlands, and deserted beaches, which would absorb some of the destructive forces. Now, with the proliferation of costly infrastructure and residential dwellings in coastal areas, these storms pose a higher risk of potential damage. The very areas where development is occurring are becoming more vulnerable to the impact of severe storms, highlighting the importance of considering and implementing adequate measures to address potential storm damage in these coastal regions (Walton County Local Mitigation Strategy Plan, 2015).

Demographically, Walton County presents a heterogeneous age distribution, encompassing a blend of younger and elderly cohorts. The median age of approximately 44 years reflects the presence of both younger families and retirees seeking a serene and picturesque environment. Ethnically, the county' population is predominantly White with smaller yet notable populations of Hispanic/Latino, African American, and other racial/ ethnic groups.

Economically, the tourism sector stands as a dominant force in Walton County, constituting 23.4 percent of the workforce, according to Walton County Economic Development Alliance in 2011, due to its renowned beach destinations, such as Santa Rosa Beach, Miramar Beach, and the New Urbanist Communities of Seaside and Rosemary Beach. Following closely behind is the trade, transportation & utilities sector, accounting for 20.3 percent of employment, while construction stands at 10.0 percent in third place. Education, health care services, and public administration also play significant roles within the top five employment sectors, reflecting the diversified economic landscape of the county (Walton County Local Mitigation Strategy Plan, 2015).

The natural environment in Walton County contributes to its distinctive appeal to visitors and tourists. The county's coastal environment along the Gulf of Mexico showcases picturesque vistas, including white sand beaches, undulating dunes, and coastal dune lakes. These lakes, a rarity worldwide, provide unique ecological habitats. Walton County is also committed to environmental conservation, with designated protected areas comprising state parks, forests, and wildlife

management zones. These preserved landscapes offer abundant opportunities for recreational activities, including hiking, fishing, and birdwatching.

The presence of wetlands and waterways further enhances the natural attributes of Walton County. Various rivers and creeks alongside Choctawhatchee Bay permeate the landscape, fostering diverse ecosystems and serving as crucial habitats for a wide range of wildlife species. This rich natural heritage encourages exploration and nurtures an appreciation for the environment.

DeFuniak Springs serves as the county seat and boasts a diverse economy. Anchored by sectors such as healthcare, education, retail, government services, and a thriving small business community, DeFuniak Springs offers a range of employment opportunities. Surrounded by the natural beauty of forests, lakes, and wetlands, the city enjoys the presence of Lake DeFuniak, a noteworthy natural resource. With a population of approximately 5,100 residents, DeFuniak Springs is a vibrant city featuring a mix of economic activities. The land area of DeFuniak Springs is approximately 12.6 square miles (32.7 square kilometers).

Freeport boasts a diverse demographic profile, and a developing economy. The city is situated along the shores of Choctawhatchee Bay, which provides opportunities for recreational opportunities and supports local ecosystems. Surrounded by lush forests and intersected by waterways, Freeport enjoys a rich environmental setting. In terms of economics, Freeport's economy is in a phase of growth and diversification, with sectors including healthcare, education, retail, and small businesses. The city is also strategically positioned for future economic expansion due to its proximity to major transportation corridors. Demographically, Freeport is a close-knit community with a population of approximately 2,600 residents, comprising a mix of permanent residents, retirees, and individuals seeking a suburban or rural lifestyle. The city reflects a diverse demographic composition, showcasing a variety of cultures, and backgrounds. Freeport occupies a land area of about 13.6 square miles (35.3 square kilometers)

Further along the coast, Miramar Beach stands as a coastal gem known for its tourism and hospitality industry. Luxury resorts, vacation rentals, gourmet restaurants, high-end retail shops, and entertainment venues thrive within this bustling city. Miramar Beach's main attraction lies in its stunning white sand beaches along the Gulf of Mexico, providing endless opportunities for beach activities and water sports. Its boundaries extend into neighboring Okaloosa County, attracting a blend of permanent residents, vacation homeowners, and rental property occupants. Miramar Beach, including its neighboring areas, covers an estimated land area of around 4.7 square miles (12.2 square kilometers).

Continuing along the Gulf Coast, we encounter Santa Rosa Beach. This coastal community is renowned for its vibrant tourism industry, offering a plethora of accommodations ranging from upscale resorts to charming vacation rentals. Its demography reflects a mix of permanent residents, seasonal visitors, and individuals seeking a coastal lifestyle, resulting in a diverse and dynamic community. Santa Rosa Beach spans a larger area compared to other cities in Walton County, with an estimated land area of approximately 31.2 square miles (80.8 square kilometers).

A summary of the existing CRS classifications for the communities in the study area is listed in **Error! Reference source not found.**. No cities in Walton County are listed in the FEMA Community Rating System Eligible Communities.

Table 1: Community Rating System for Walton County. Effective April 1, 2023.

Community #	**Community Name**	**CRS Class Rating**	**Premium Discount for SFHA**	**% Discount for Non- SFHA**	**Status**
120317	Walton County	6	20%	10	Cycle

(Source Data: FEMA)

Figures 12 and 13 is the county-wide report show the current and projected land use for the County. Based on the 2017 future land use for Walton County, only 7.07% of the land use in the county is urban and built up, and water/wetlands makes up 29.16% of the land use. The majority of land is upland forest, with 48.3%, as shown in **Error! Reference source not found.**.

Table 2. Land Use in Walton County (Prepared by FAU from future land use map) versus land use in the entire watershed

Level 1 Land Use-Land Cover Type	**Area (Acres)**	**Percentage of Total**
Agriculture	52958.94669	7.17%
Barren Land	9242.05986	1.25%
Rangeland	40326.66002	5.46%
Transportation, Communication, and Utilities	11815.69287	1.60%
Upland Forest	356796.0541	48.30%
Urban and Built-Up	52194.79061	7.07%
Water	61593.80508	8.34%
Wetlands	153759.9055	20.82%
Total	**738687.9147**	**100.00%**

(Source Data: (NWFWMD 2017)

Walton County has a history of flooding and has implemented various measures for flooding mitigation over the years (see section 1.12 for more details). The County has experienced flooding primarily due to heavy rainfall events and proximity to large water bodies such as the Gulf of Mexico, Choctawhatchee Bay, and numerous rivers and creeks. The topography of the region, with low-lying areas in the coastal areas and wetlands, also contributes to flood vulnerability. The proximity to the ocean (Gulf of Mexico) makes the county vulnerable to sea level rise. Over the years, Walton County has faced multiple flooding incidents, including:

- March 1997: Heavy rainfall led to significant flooding throughout the county, resulting in property damage and road closures.
- April 2009: Intense storms caused widespread flooding, damaging homes and infrastructure and resulting in the declaration of a state of emergency.
- April 2014: Heavy rainfall caused severe flooding, leading to the evacuation of some residents and the closure of roads.

Today, the goal of a stormwater management system in many communities is to keep the community as a place to live and do business while limiting risk from damage due to flooding. The short-term impacts from stormwater include flooding in low-lying areas and standing water in areas with limited soil storage capacity. Less common, but of increasing frequency, is the potential for extensive inundation of some areas, especially low-lying areas, during periods with high groundwater levels and groundwater impacted by sea level rise. As a result, there is a need to understand the economic impact of flooding events and to create cost-effective stormwater infrastructure and policy solutions to protect property. This means preserving as much property and economic activity as possible without disrupting current activity or expending funds on inappropriate projects with limited long-term or social value.

1.1 Surface Topography

Topography is a key parameter that influences many of the processes involved in flood risk assessment, and thus, up-to-date, high-resolution, high-accuracy elevation data are required. In order to meet the requirements for FEMA Risk Mapping, Assessment, and Planning (RiskMAP), 1-meter (2015 to present) and 1/9 arc-second (~ 3-meter) (2010 -2015) LiDAR DEMs were acquired. The 1 m × 1 m LiDAR tiles were kriged to create a topographic map of the study area (**Error! Reference source not found.**). This accuracy meets the 3DEP Quality Level 2 vertical root mean square error accuracy threshold of ±10 cm for FEMA (Arundel et al., 2015). The LiDAR used for this basin was 2016.

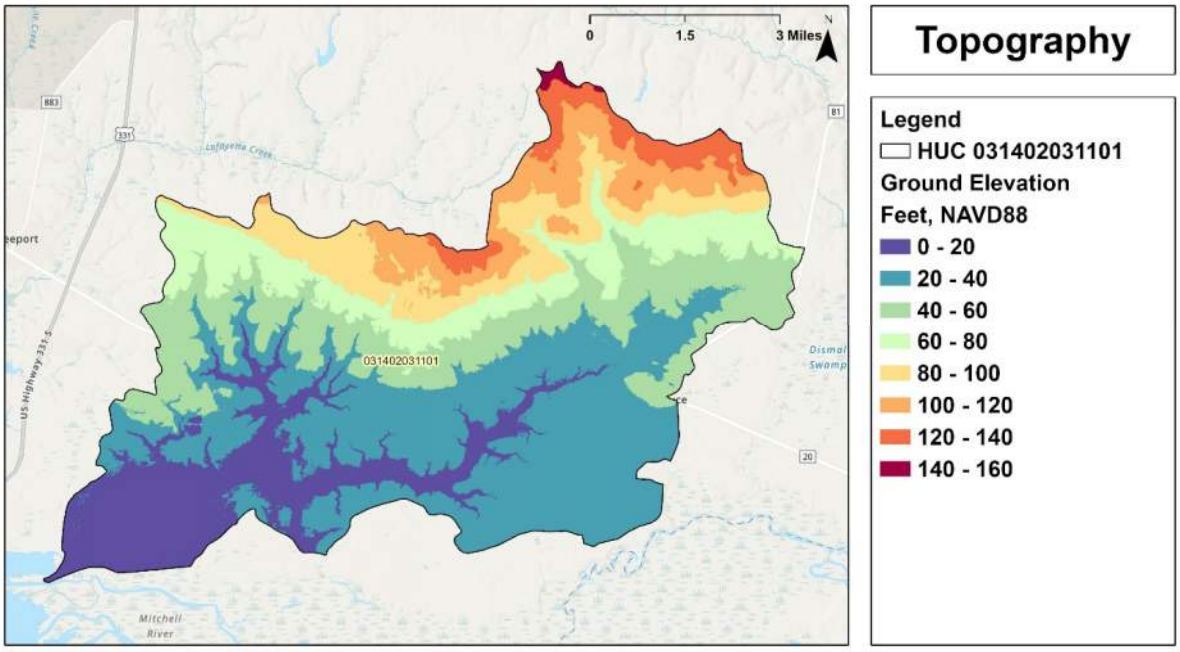

Figure 4. Topographic map of the HUC 031402031101 sub-watershed, processed by FAU. (Data Source: USGS)

1.1.1 Geomorphological Considerations

Walton County's coastal area is characterized by the presence of barrier islands, extensive sandy beaches, and coastal dune systems. These features are influenced by the dynamic processes of wave action, tidal currents, and wind-driven sediment transport. The shoreline is subject to natural changes, including erosion and accretion, which significantly shape the coastal geomorphology. Inland Walton County exhibits a mix of wetlands, forests, rolling hills, and rivers. These landforms are influenced by a combination of factors, including underlying geology, fluvial processes, and the region's hydrological regime.

Like many areas in Florida, Walton County is underlain by limestone formations. The specific composition and properties of these limestone formations in Walton County may vary. However, limestone is generally known for its porous nature, which allows for the absorption and storage of water. Underground aquifers within the limestone formations can hold significant volumes of freshwater, contributing to the region's water resources.

For context, the FIRM panel index of HUC 031402031101 sub-watershed is shown in **Error! Reference source not found.**.

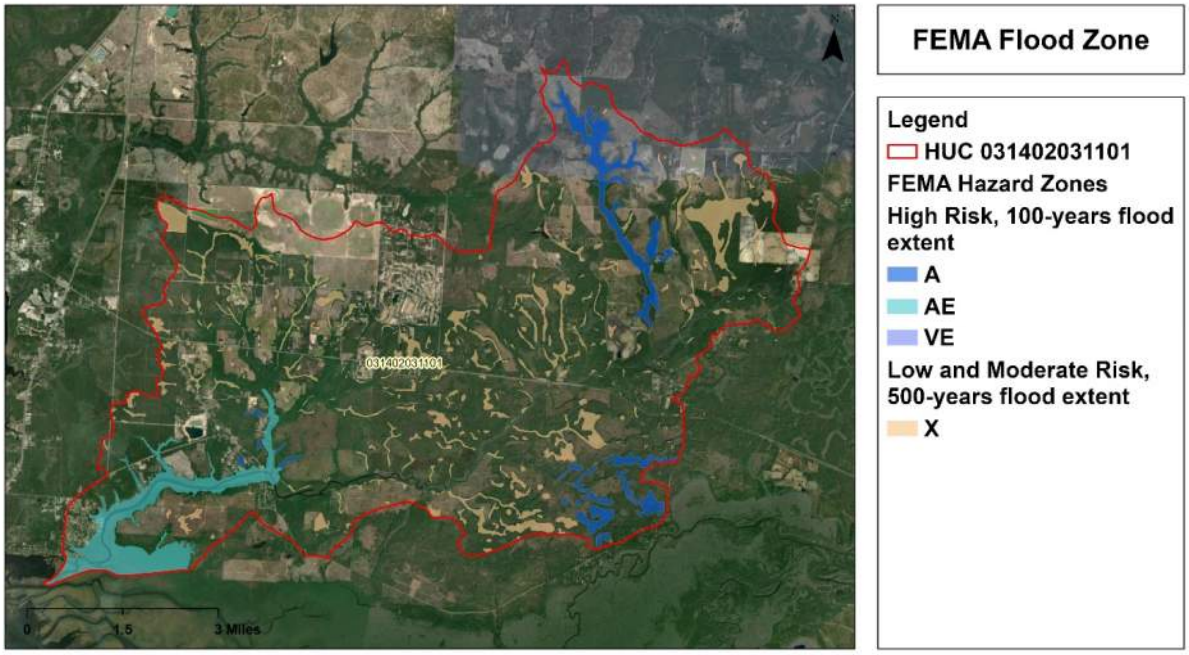

Figure 5. FEMA Flood Zone map (2020) for HUC 031402031101 sub-watershed, processed by FAU.
(Data Source: FEMA)

1.1.2 Waterway Features

In Walton County, Florida, the waterway features are primarily influenced by the presence of rivers, creeks, bayous, and the proximity to the Gulf of Mexico. To the south of Walton County lies the Gulf of Mexico. Sandy beaches, barrier islands, and the open waters of the Gulf itself characterize the coastline along the Gulf. The Gulf of Mexico influences the coastal processes, including wave action, tidal currents, and sediment transport along the shoreline. The combination between sea level rise and King tide would have detrimental consequences for the county costal area, including the sub-watershed 031402031101 as it will reach the area thought Choctawhatchee Bay.

Walton County is home to several rivers and creeks that meander through its landscape. These waterways provide drainage for the inland areas and contribute to the overall hydrological system. Examples of significant rivers in the county include the Choctawhatchee River and the Shoal River. In addition, Walton County features bayous and estuaries that connect inland water systems to the Gulf of Mexico.

Choctawhatchee Bay serves as a vital estuarine ecosystem, where freshwater from rivers and creeks mixes with the saltwater from the Gulf of Mexico, serving as a vital estuarine ecosystem.

This unique brackish water environment supports a rich diversity of flora and fauna, including various fish species, shellfish, migratory birds, and wetland vegetation, contributing to the overall biodiversity of the region. It also plays a significant role in the local economy of Walton County as it supports commercial and recreational fishing industries, providing livelihoods for local fishermen and contributing to the seafood industry, while also offering a range of recreational opportunities for residents and visitors alike, such as boating, kayaking, paddle boarding, and sailing. **Error! Reference source not found.** shows the bathymetry offshore.

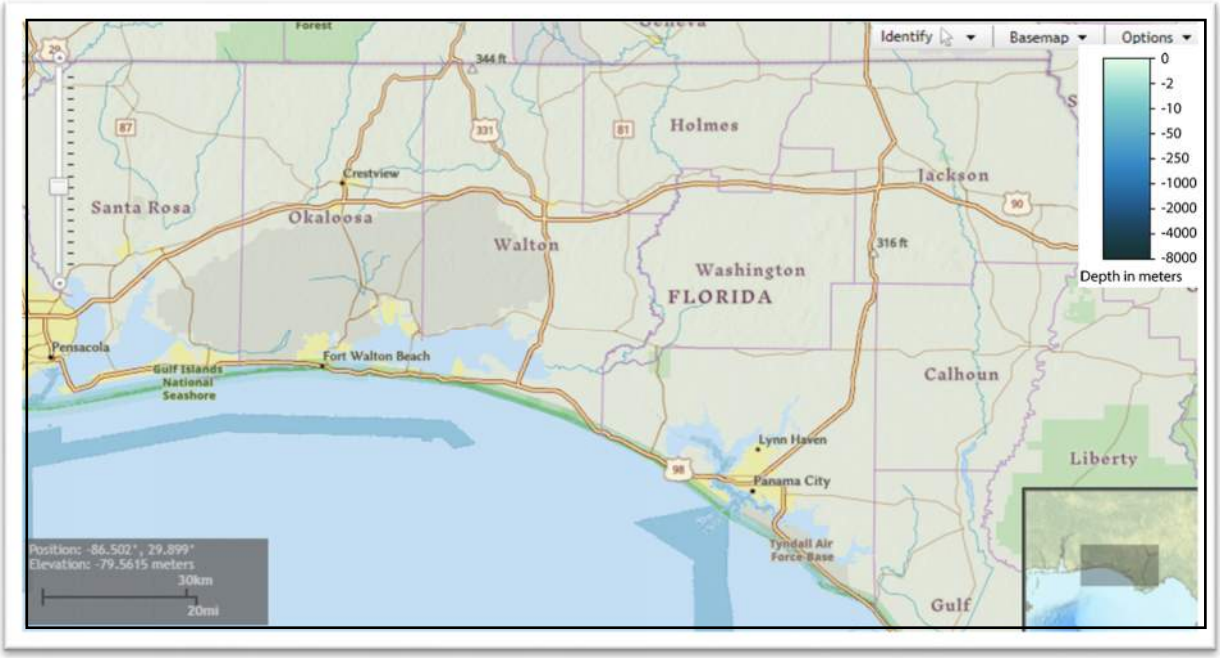

Figure 6. Bathymetry map of the shore of Walton County and surrounding counties of Florida Panhandle.
(Source: ncei.noaa.gov/maps/bathymetry/)

Numerous tributaries exist throughout both the freshwater and estuarine portions of the watershed and can influence the overall hydrology of the area depending on rainfall and regional hydrological conditions. **Error! Reference source not found.** shows the location of all four surface water stations along with ground water stations (wells) and the drainage network of Walton County.

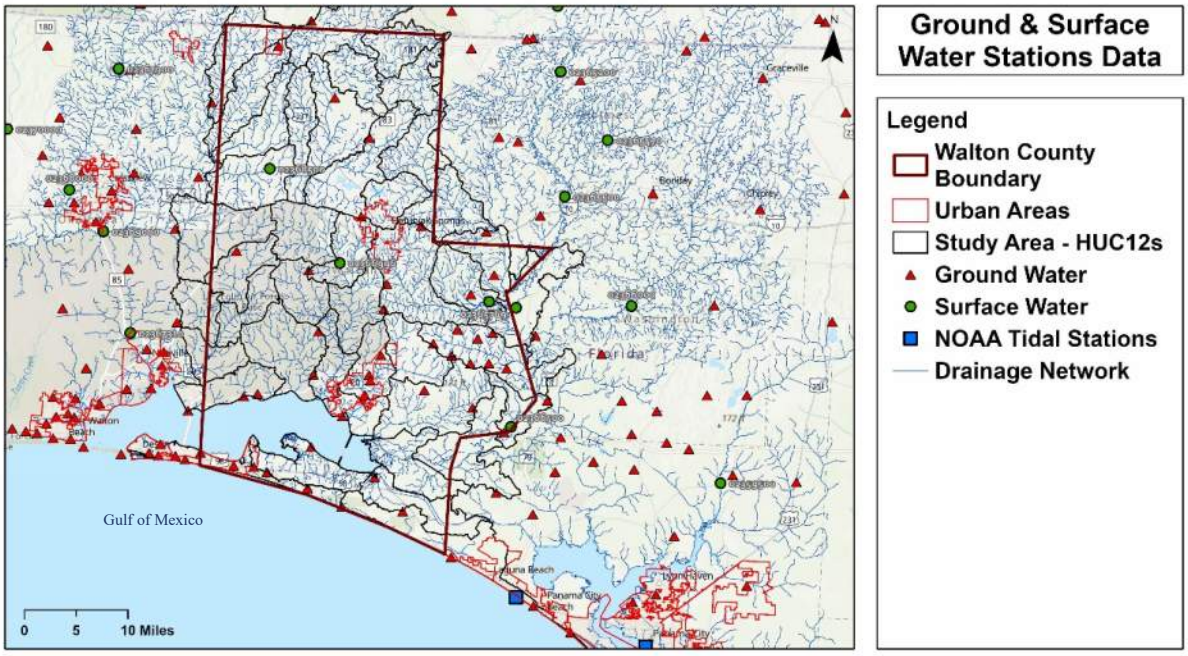

Figure 7. Ground & Surface Water Stations with drainage network for Walton County, processed by FAU.
(Data Source: USEPA – National Hydrographic Dataset (NHD) and NOAA's Tides)

1.1.3 Hydrologic Boundaries

The geographic area of the subject sub-watershed should be clearly defined to ensure that implementing the WMP will address all the major sources and causes of impairments and threats. Although there is no rigorous definition or delineation of this concept, one way to identify the geographic extent of the watershed master planning effort is to consult the United States Geological Survey (USGS) map of hydrologic units. A hydrologic unit is part of a watershed mapping classification system showing various areas of land that contribute surface water runoff to designated outlet points, such as lakes or stream segments. USGS designates drainage areas as sub-watersheds (including smaller drainages) numbered with 12-digit hydrologic unit codes (HUCs), nested within watersheds (10-digit HUCs). These are combined into larger drainage areas called subbasins (8 digits), basins (6 digits), and subregions (4 digits), which make up the large regional drainage basins (2 digits).

Region>>Subregion>>Basin>>Sub-basin>>Watershed>>Sub-watershed

The major water bodies in the HUC 031402031101 sub-watershed include:

- Black Creek
- Camp Creek
- Turnpike Branch
- Walker Branch
- Pate Branch
- Joyce Branch
- Silcox Branch
- McIver Branch
- Little Black Creek

Given that stream flow data are critical for estimating flooding, **Error! Reference source not found.** shows the historical streamflow during June 2022 to July 2023 for USGS 02366500. However, as there are only four surface water station within Walton County, it was necessary to use the nearest station to the sub-watershed 031402031101, which is USGS 02366500 Choctawhatchee River NR Bruce FLA.

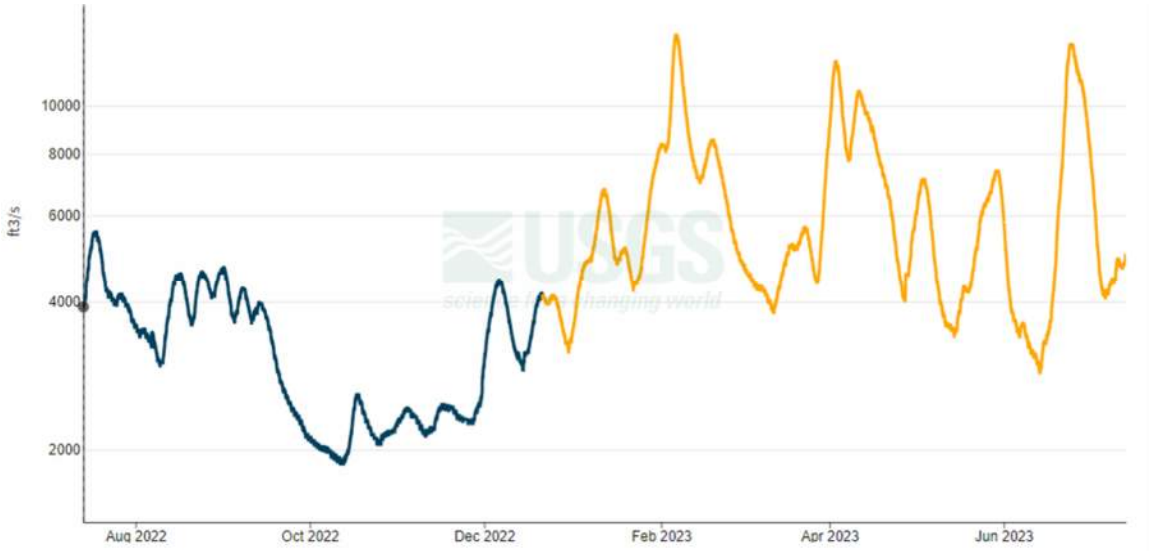

Figure 8. Average streamflow for Choctawhatchee River NR Bruce FLA (USGS 02366500 Surface-Water, June 2022 to July 2023).
(Source: USGS Water Data Services, available at https://waterdata.usgs.gov/monitoring-location/02366500/#parameterCode=00065&period=P365D)

1.2 Groundwater

In this region of Florida, there is a direct interaction between groundwater and surface water. In addition to low land elevations and topographic relief, the groundwater and surface water are

controlled by the canals, rivers, and tides. Since there is a limited number of groundwater monitoring stations, the strong relationship between groundwater and surface water was leveraged to develop a 99th- percentile surface of the water table elevation for mapping purposes. To establish a common date for modeling, the recorded groundwater table elevations were sorted in ascending order to determine the 98th - 100th percentile date of occurrence in Excel®, following the procedure detailed in Romah (2011). This procedure was automated for this effort using a python code to process the groundwater data more efficiently. Outliers and anomalous groundwater levels in the database are initially identified (e.g. catastrophic storm events) and replaced by region-specific mean values based on observations available from the nearest well. Missing date-specific data are estimated using simple temporal interpolation based on observations available in time. If a station (or monitoring well) data contains large amounts of missing data, it is not used in the generation of the groundwater surface.

In Walton County, the average annual rainfall is abundant, reaching 65 inches at DeFuniak Springs. This rainfall predominantly infiltrates the sand-and-gravel aquifer and eventually seeps into streams or the underlying artesian Floridan aquifer. The county's two major aquifers are the sand-and-gravel aquifer and the Floridan aquifer. While the sand-and-gravel aquifer provides water for rural domestic use and plays a crucial role in water storage and streamflow maintenance, it also serves as a recharge source for the Floridan aquifer. Water from the sand-and-gravel aquifer contains varying levels of dissolved solids, pH, and iron content. The Floridan aquifer, being the primary water supply source, underlies the entire county and yields around 500 to 1,000 gallons per minute from wells, except along the Gulf Coast where the permeability is lower. Recharged by leakage from the sand-and-gravel aquifer, the Floridan aquifer's movement is predominantly southward away from the potentiometric high in northwestern Walton County. It discharges through springs, seeps along the Choctawhatchee River, and by wells. In southern Alabama, the Floridan aquifer is directly recharged by rainfall when it is exposed or close to the land surface. (Bureau of Ecology, 1974).

Once a common time period is determined across the majority of shallow groundwater wells, canal data can be gathered for that common date (and two days prior, in the event the canals were deliberately lowered). Data was obtained from the NWFWMD and processed by FAU at cwr3.fau.edu. Between stations, an ArcGIS tool permits a line to be drawn to replicate the canals and establish points in a gradient between stations. The same is true for the ocean, but it is a constant head boundary. The canals form boundary conditions for the screening tool on the edges of the basin and affect localized groundwater. The tide issue is resolved by using the common date for high tide.

Error! Reference source not found. shows the drainage network of HUC 031402031101 and points out the location of the ground water stations in the surroundings. A groundwater-surface layer for the HUC 031402031101 sub-watershed was created using several datasets including water level data from USGS and NWFWMD and groundwater elevation contour maps. The

datasets were used to generate a raster surface of the groundwater elevation (**Error! Reference source not found.**).

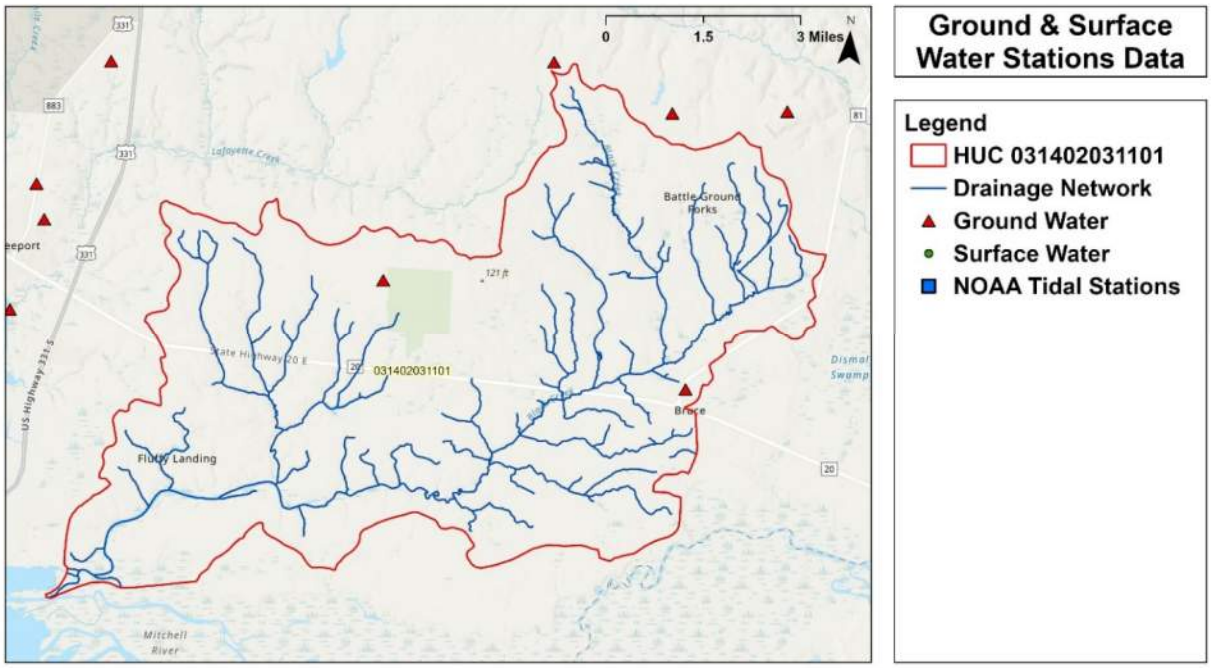

Figure 9. Ground and Surface Water Stations in the HUC 031402031101 sub-watershed, processed by FAU.
(Data Source: USEPA – National Hydrographic Dataset (NHD)

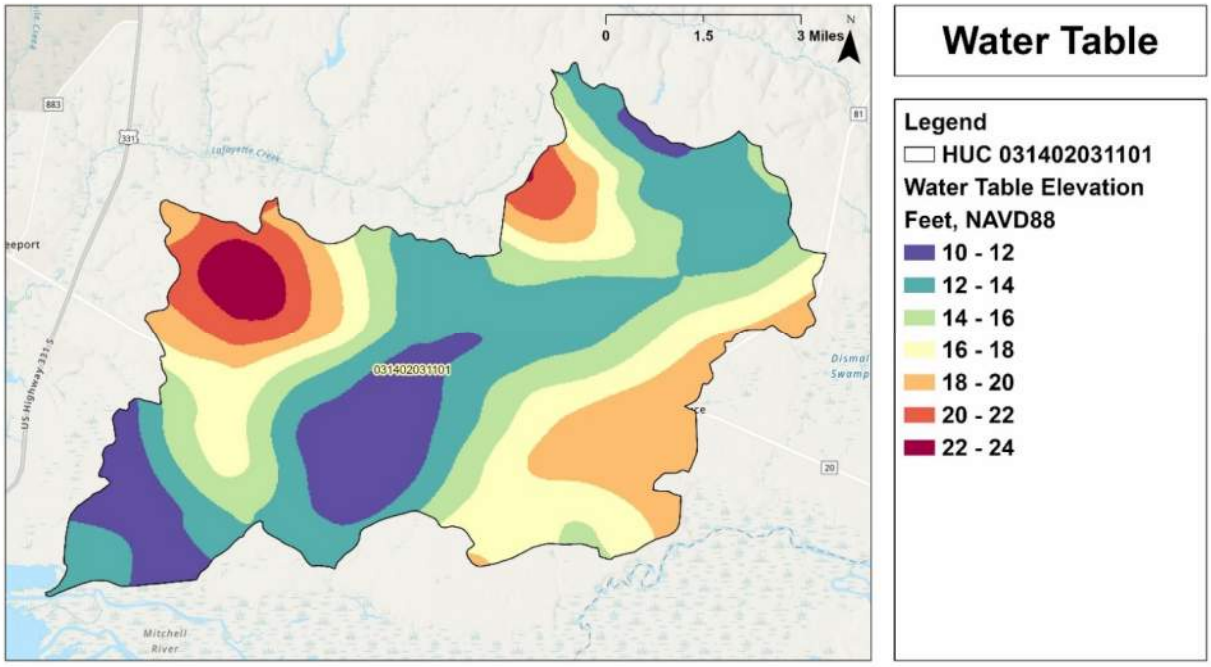

Figure 10. Elevation of the top of the surface groundwater layer for the HUC 031402031101 sub-watershed, created by multiple linear regression analysis – elevation NAVD88, processed by FAU. (Data Source: USGS and NWFWMD)

1.3 Surface Water/Tides

Historically, surface water and tides have been an important factor in determining how much freshwater is delivered, how fast this water enters wetlands and estuaries, and the quality of that water. Evapotranspiration and rainfall do not coincide in the study area, which makes water supply planning difficult. **Error! Reference source not found.** shows the average precipitation over Walton County for every month of the year between 2011 and 2023 - each rectangle is a month and each column is a year. The 12-month total precipitation decreased 7.5 inches from May 1900 to April 2023. From May 1900 to April 2023, the average 12-month total precipitation was 60.5 inches for the entire county.

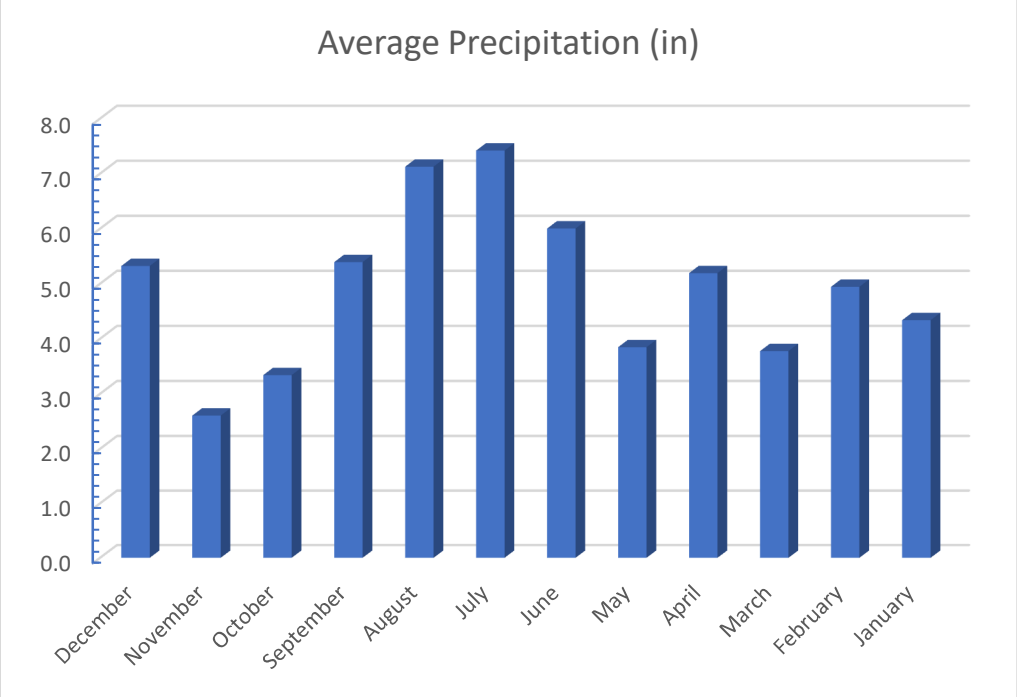

Figure 11. Monthly precipitation in Walton County, FL (2011-2023).
(Data Source: Florida Weather Data, available at https://data.usatoday.com/weather-data/walton-county/12131/1975-04-01/table/)

While the topography (Section 1.1) and native soil (Section 1.4) create an environment that is highly permeable and capable of infiltrating significant percolation into the soil, changes in land use and land cover have resulted in water falling on impervious areas, where the water collects in pools or runs off rapidly, in direct contrast to the natural condition. This runoff flowing over impermeable regions can lead to larger scale flooding.

Tidal data can be gathered from NOAA tidal gages and other gages monitored by local governments. The location of tide gages is important to ensure they accurately depict tides, as opposed to inland waters. To set a boundary for the coastal areas, the high tide on the common date from 12/03/2018 to 12/10/2018 was selected. **Error! Reference source not found.** shows the two closest tide stations to Walton County. Since there is none NOAA tide station in Walton County, the Panama City Beach station (8729210) was used.

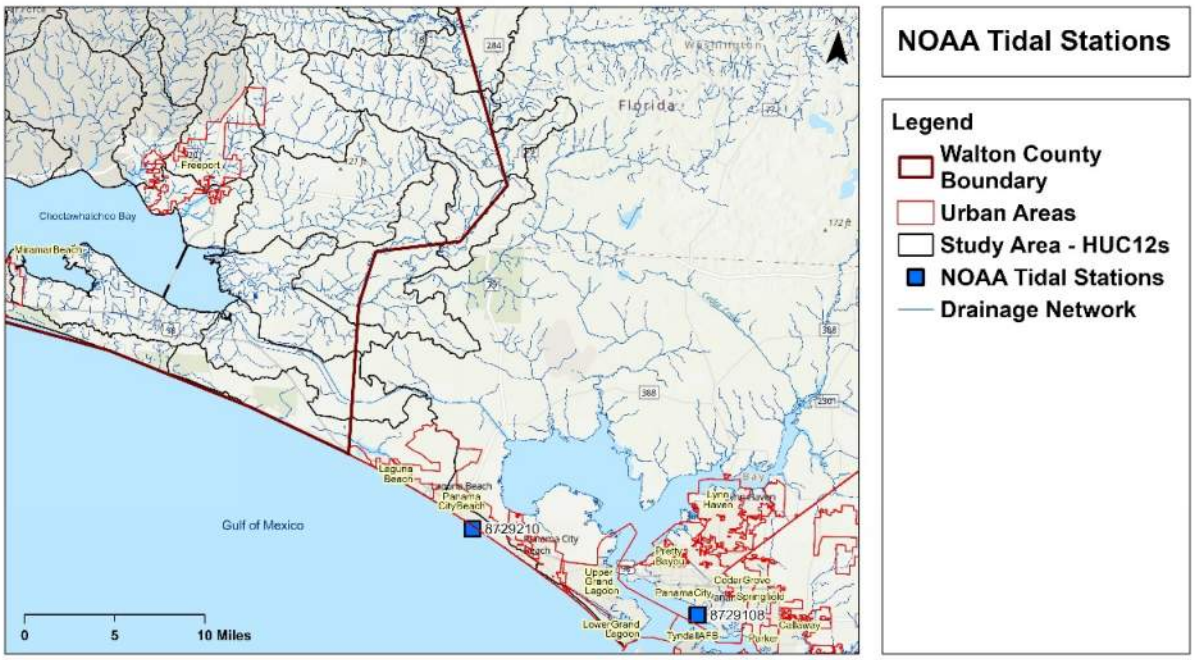

Figure 12. Locations of Florida tidal stations maintained by NOAA near to Walton County, processed by FAU.
(Data Source: USEPA – National Hydrographic Dataset (NHD) and NOAA's Tides)

1.4 Soils

Soil can store water if there is adequate distance between the topographic surface and the groundwater, and the soil types are capable of absorbing the water. Soil storage capacity is the volume of soil pores in the unsaturated zone that is available to store infiltrated stormwater (Gregory et al., 1998). Throughout Florida, it is common to have large volume storm events that fill the voids in the unsaturated zone as shown in Figure 13.

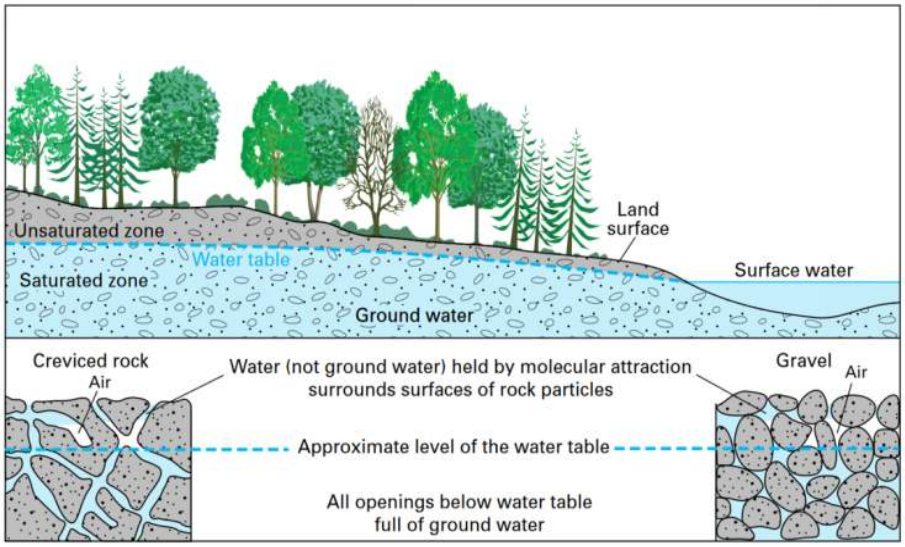

Figure 13. Zones where underground water exists.
(Source: USGS, 2020)

The unsaturated zone is the portion of the subsurface above the water table that contains soil/rock and air and water in its pores as shown in Figure 14. This zone affects the rate at which the aquifer is recharged by controlling water movement from the surface of the land downward towards the aquifer. During rain events, the soil voids fill up quickly resulting in the water table rising to the surface, and the surplus rainfall becomes runoff.

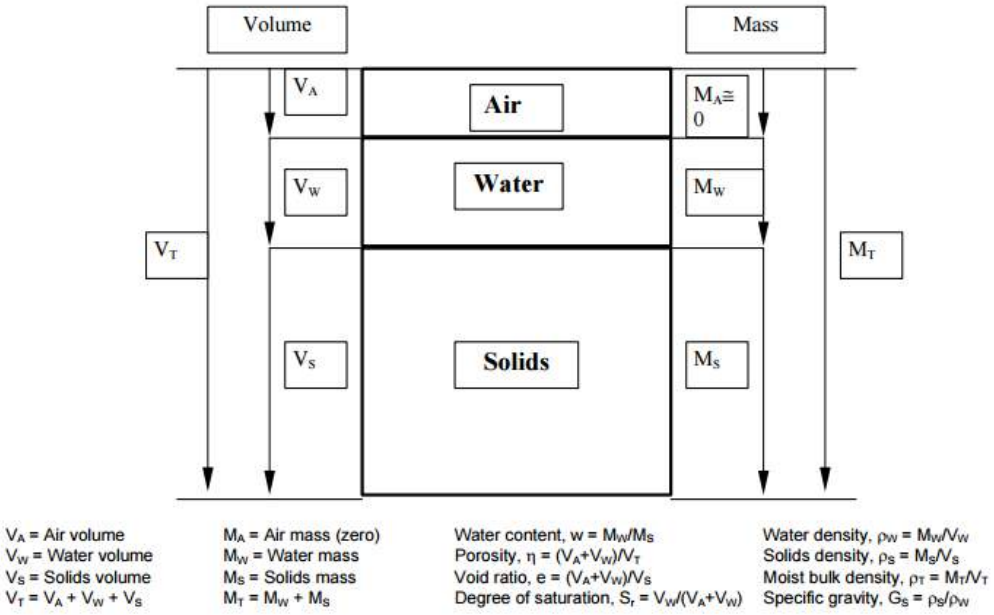

Figure 14. Saturated zone soil phase diagram and definitions.
(Source: Gregory et al., 1998.)

Soil data is available from the United States Department of Agriculture (USDA) or other agencies in the form of maps that can be incorporated as a GIS layer. The Gridded SSURGO (gSSURGO) dataset from USDA is chosen. This dataset is similar to the standard product from USDA Natural Resources Conservation Service (NRCS) Soil Survey Geographic (SSURGO) database, but is in the Environmental Systems Research Institute, Inc. (ESRI®) file geodatabase format. A file geodatabase allows for statewide or even Conterminous United States (CONUS) tiling of data. The gSSURGO dataset contains all of the original soil attribute tables in SSURGO. All spatial data are stored within the geodatabase instead of externally as separate shape files. Both SSURGO and gSSURGO are considered products of the National Cooperative Soil Survey (NCSS). **Error! Reference source not found.** shows the unsaturated zone found by the difference between the groundwater elevation layer and surface topography.

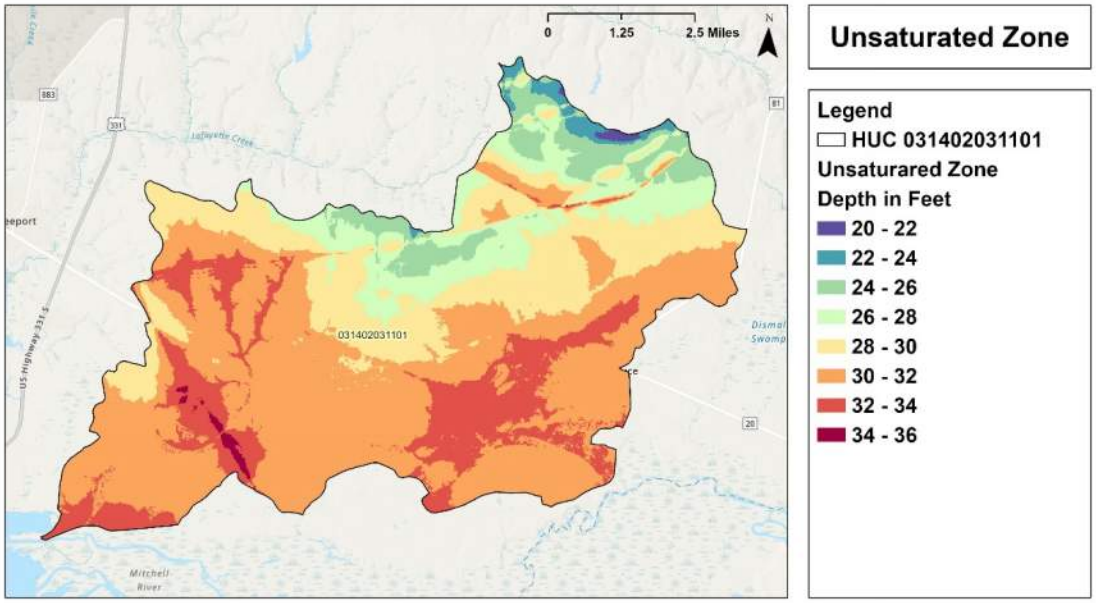

Figure 15. Unsaturated zone map for HUC 031402031101, processed by FAU.

The available water storage from USDA derived for the soil layer (0-150 cm or 0-5 ft) statewide is shown in **Error! Reference source not found.**, which covers most of Florida with a spatial resolution of 10 m. The unit is in cm. As a result of applying this layer to the study area (**Error! Reference source not found.**), the estimated soil storage capacity can be illustrated. A significant portion of the basin demonstrates a moderately favorable soil storage capacity, falling within the range of 24 to 34 feet of remaining capacity.

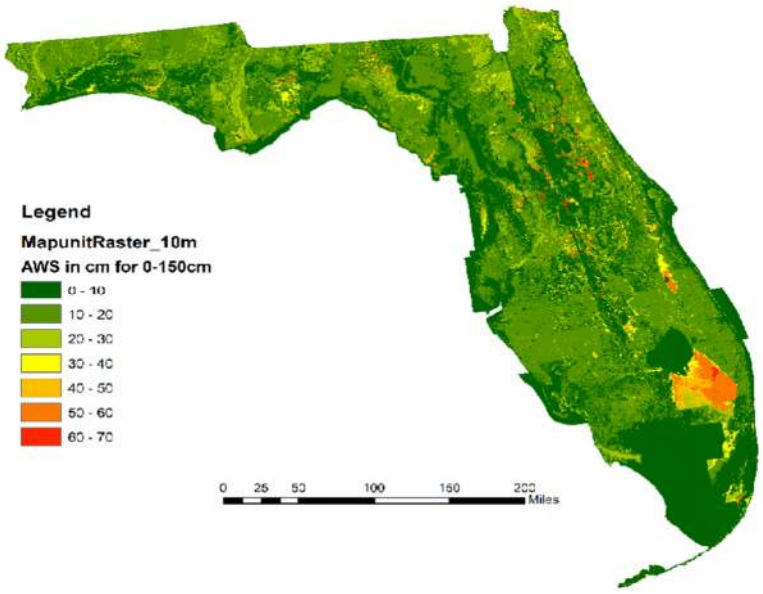

Figure 16. Available water storage derived from the gSSURGO soil database for all of Florida, as processed by FAU.
(Data Source: USDA - SSURGO)

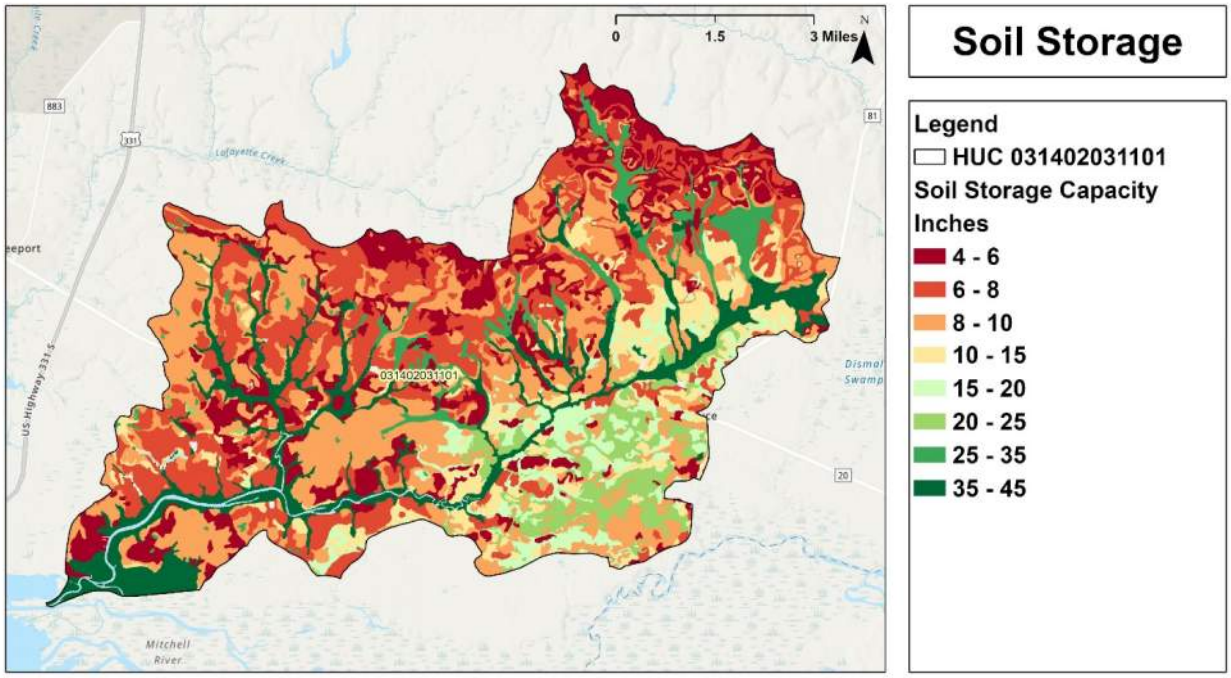

Figure 17. Water storage capacity of soil for the HUC 031402031101, processed by FAU.

Lastly, **Error! Reference source not found.** shows the water holding capacity for the basin, which refers to the capacity of a particular soil texture to retain water against the force of gravity.

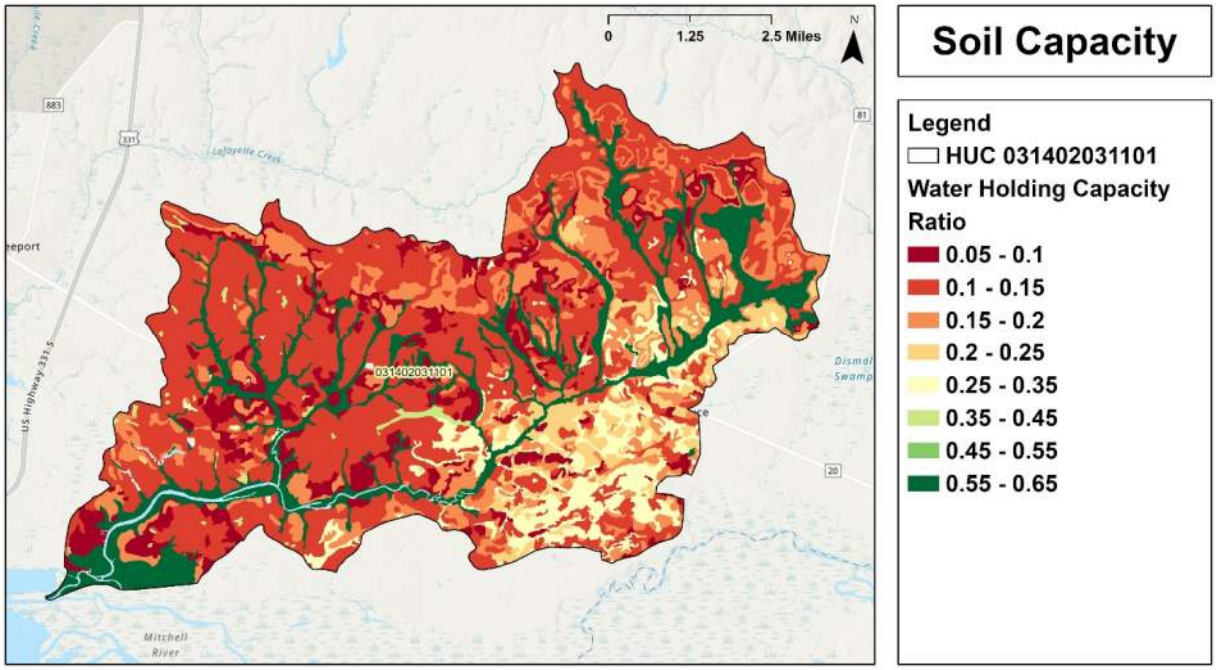

Figure 18. Water Holding Capacity (ratio) for the HUC 031402031101, processed by FAU.

1.5 Land Cover

The USGS produces the NLCD of nationwide data on land cover at a 30-m resolution with a 16-class legend based on a modified Anderson Level II classification system. NLCD is coordinated through the 10-member Multi-Resolution Land Characteristics Consortium (MRLC) to provide digital land cover information nationwide. For the conterminous United States, NLCD 2016 contains 28 different land cover products characterizing land cover and land cover change across 7 epochs from 2001-2016, urban imperviousness and urban imperviousness change across 4 epochs from 2001-2016, tree canopy and tree canopy change across 2 epochs from 2011-2016 and western U.S. shrub and grassland areas for 2016 (**Error! Reference source not found.**).

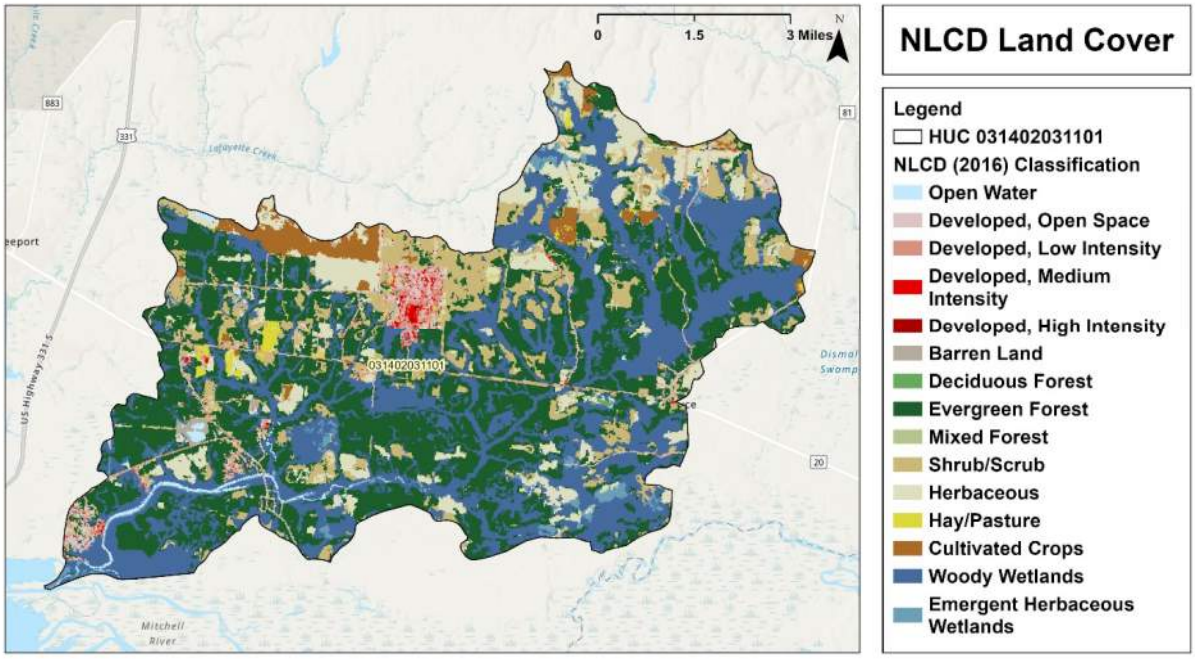

Figure 19. Land use in the HUC 031402031101 (from the NLCD 2016 database), processed by FAU.
(Source Data: NLCD, 2016)

The dataset is derived from the Florida Land Use Cover Classification System (FLUCCS), which is digitized by photo-interpretation on county-based aerial photography with varying resolution in the range of 4 in - 2 ft pixel. The NLCD2016 has a 30-meter resolution derived from Landsat imagery. Hence, the NLCD maps appear much coarser and pixelated compared to the 2023 Florida Geographic Data Library (FGDL) (https://fgdl.org/fgdlmap/) maps. A view of the latter is provided in **Error! Reference source not found.**. The future land use maps need to be used for the final land cover, as adjusted for future stormwater improvements set by regulatory standards.

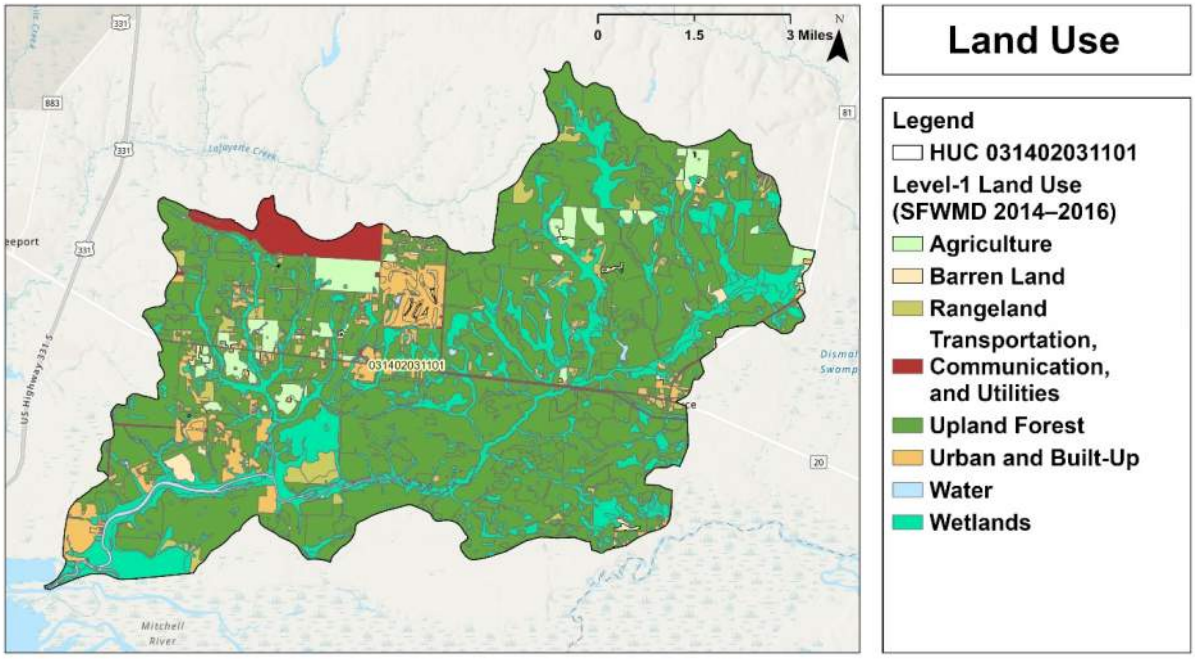

Figure 20. Land use in the HUC 031402031101 as processed by FAU.
(Source Data: 2023 Florida Geographic Data Library (FGDL) database))

In the HUC 031402031101 sub-watershed, the predominant land cover is upland forest, accounting for 53.51% of the area. Wetlands comes in second at 23.50%, followed by Transportation, Communication, and Utilities at 8.26%. Developed land constitutes a minor portion, with only 3.80% categorized as urban and built-up, as indicated in **Error! Reference source not found.**. **Error! Reference source not found.** shows the roughness of the surface.

Table 3. Land use for HUC 031402031101 sub-watershed

Level 1 Land Use Land Cover Type	**Area (Acres)**	**Percentage of Total**
Agriculture	1388.84	2.50%
Barren Land	190.16	0.34%
Rangeland	1472.21	2.65%
Transportation, Communication, and Utilities	4598.41	8.26%
Upland Forest	29773.44	53.51%
Urban and Built-Up	2114.08	3.80%
Water	3031.52	5.45%
Wetlands	13073.72	23.50%
Grand Total:	**55642.39**	**100.00%**

(Source Data: 2023 Florida Geographic Data Library (FGDL) database))

Table 4. Roughness and CN Values for Each Land Use Code

DOR Code	Use	Impervious %	Roughness
0	Vacant	0	0.4
1	Single Family	29	0.25
2	Mobile homes	21	0.05
4	Condos	60	0.05
7	Vacant –to be developed	0	0.4
8	Multifamily	60	0.05
TH 101	Townhomes	91	0.025
94	Road Right-of-Ways	50	0.08
	Open water	100	n/a
All others	Commercial, etc.	50	0.07

1.6 Precipitation

Rainfall used in the screening tool is based on the SFWMD 3-day 25-year storm, but can be modified for any rainfall event using the accumulated rainfall table obtained from NOAA Atlas 14 Point Precipitation Frequency Estimates (https://hdsc.nws.noaa.gov/hdsc/pfds/pfds_map_cont.html). **Error! Reference source not found.** shows the 3-day 25-year rainfall map based on the NOAA Atlas 14 dataset for the whole state. **Error! Reference source not found.** to **Error! Reference source not found.** rainfall 1-day 100-year, 1-day 10-year, and 1-day 5-year storm event scenarios, in inches.

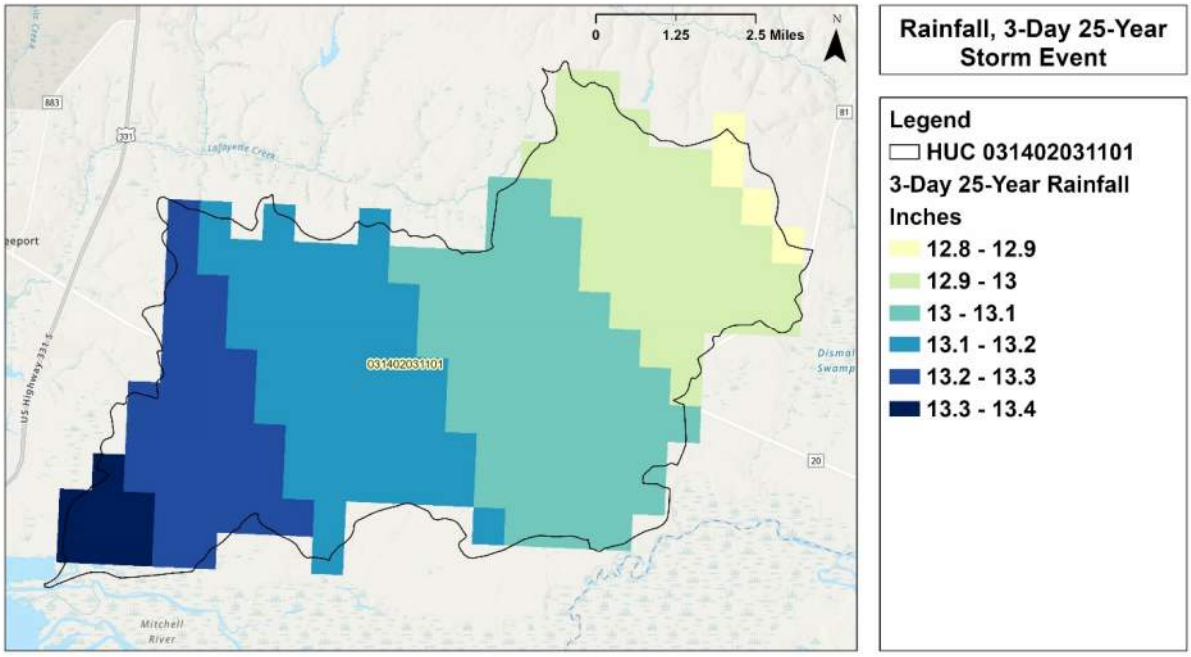

Figure 21. Rainfall distribution map across HUC 031402031101 sub-watershed, for 3-day 25-year storm event, processed by FAU.

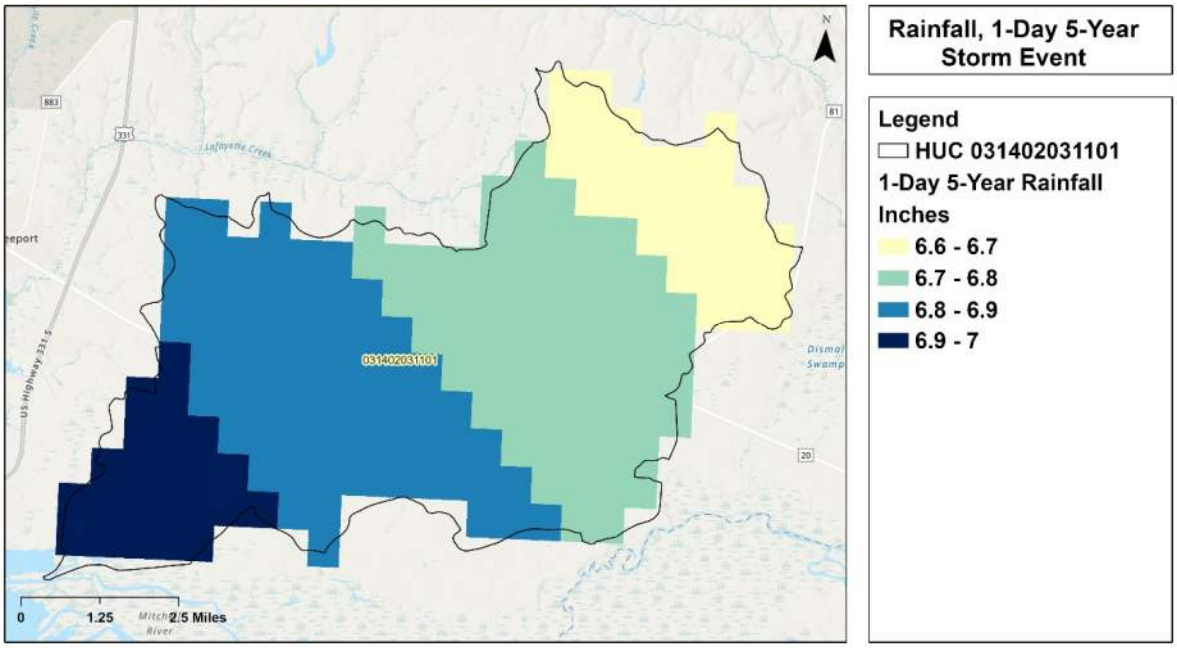

Figure 24. Rainfall distribution map across HUC 031402031101 sub-watershed, for 1-day 5-year storm event, processed by FAU.
(Source Data: NOAA Atlas 14 Database)

1.7 Open Space

Open space is defined as areas that are exempted from development. Generally, this means one or more of the following qualifiers exist:

1. Land that is valuable for recreation, forestry, fishing, or conservation of wildlife or natural resources
2. Land that is a prime natural feature of the state's landscape, such as a shoreline or ridgeline
3. Land that is habitat for native plant or animal species listed as threatened, endangered, or of special concern
4. Land that is a relatively undisturbed example of an uncommon native ecological community
5. Land that is important for enhancing and conserving the water quality of lakes, rivers, and coastal water
6. Land that is valuable for preserving local agricultural heritage
7. Proximity to urban areas or areas with open space deficiencies and underserved populations
8. Vulnerability of land to development
9. Stewardship needs and management constraints
10. Preservation of forest land and water bodies that naturally absorb significant amounts of carbon dioxide

Permanent protection of sensitive areas can provide critical water quality protection and can be achieved through partnerships with landowners, municipalities, land trusts and state agencies. There is limited land in the study area that has been protected via acquisition by federal, state or local agencies, has conservation easements or is designated as wetlands or areas of critical concern. Agricultural land and other land cover will come from the land cover map (in Section 1.5). Added to this will be the water bodies discussed in Section 1.9, which serve a related condition to open space.

1.8 Impervious Areas

Impervious areas do not permit the infiltration of rainfall to groundwater, and because the water cannot infiltrate, it runs off faster. Faster runoff means that flows to water bodies and storm sewers occur faster and with higher peaks. The result is a disruption of the natural and potentially the planned hydrology. Impervious areas include pavement, buildings, and other areas that reduce runoff capacity. In other words, developed areas have much higher imperviousness than open spaces that are natural or agricultural.

The NLCD provides nationwide data on land cover and land cover change at a 30-m resolution with a 16-class legend based on a modified Anderson Level II classification system. Systematically aligned over time, the database offers the ability to understand both current and historical land cover and land cover change to enable assessment of trends. Using the NLCD 2016 dataset, a layer was created by using only three categories out of the 13 to identify impervious areas such as primary roads in urban areas, secondary roads in urban areas, and tertiary roads in urban areas. The new layer was then converted to match the 3-meter spatial resolution from the DEM and the standard State Plane Coordinate system. **Error! Reference source not found.** shows the impervious areas derived from the NLCD 2016 as updated by the future land use map.

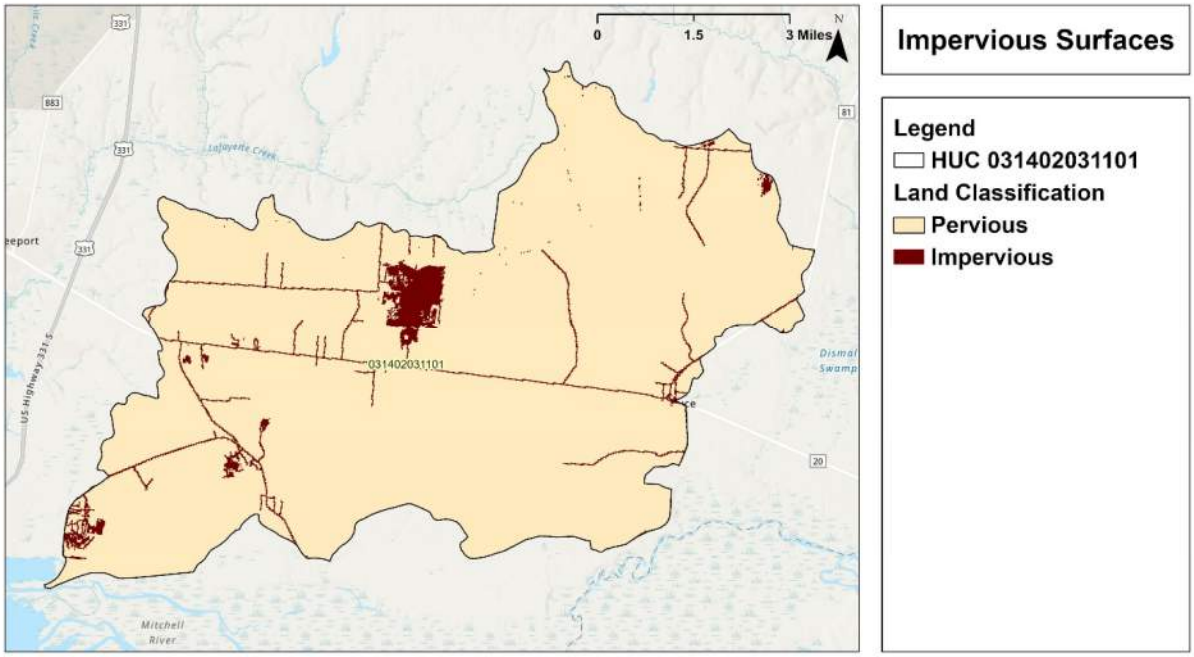

Figure 25. Impervious area map for the HUC 031402031101 sub-watershed, processed by FAU. (Source Data: NLCD, 2016)

1.9 Water bodies

Water bodies were defined in the statewide land use land cover dataset to set soil water holding capacity to zero in model simulations (**Error! Reference source not found.**). Note that tiny water bodies may be missing from the maps. Soils were discussed previously in Section 1.4.

1.10. Natural Resources

Understanding the study area's natural resources is critical to identifying potential sources of water quality degradation and areas to designate for conservation, protection, and restoration. One possible goal of watershed master planning is to protect terrestrial wildlife, aquatic habitat, and buffer zones. USGS maintains important sources of information on physical and geographical features as well as soil and mineral resources, surface and ground water resources, topographic maps, and water quality monitoring data. The USDA's Natural Resources Inventory (NRI) (www.nrcs.usda.gov/technical/NRI) is a survey of information on natural resources on non-federal land in the United States that captures data on land cover and land use, soil erosion, prime farmland soils, wetlands, habitat diversity, erosion, conservation practices, and related items. Since 2001, the NRI has been updated continually with annual releases of NRI data from all 50 states. The information provided can be used for addressing agricultural and environmental issues down to the county or cataloging unit level. Therefore, this data can be used to determine erosion and site-specific soil characteristics for certain land uses such as croplands, pasturelands, forestlands, etc., but the data is typically provided as inventories, not GIS layers.

1.11 Demographics

Demographics data is important for determining several key indicators for watershed master planning such as the ability to pay for improvements, social justice issues, land acquisition costs, property/land use, and communication strategies. The US Census has databases at the census tract level. Based on the census data for the study area, **Error! Reference source not found.** outlines population and racial composition demographics.

Table 5. Demographics and Housing Characteristics of Cities and Towns in Walton County.

Demographic Parameter	**Miramar Beach**	**Freeport**	**DeFuniak Springs, City**	**Paxton**	**Rosemary Beach**	**Santa Rosa Beach***	**Walton County**

1.12 Stormwater Infrastructure Inventory

Local community stormwater systems consist of drainage ditches, storm sewers, retention ponds and other facilities constructed to store runoff or carry it to a receiving stream, lake, ocean, or other waterbody. Other man-made features include yards and swales that collect runoff and direct it to the sewers and ditches. When most of these systems were built, they were typically designed to handle the amount of water expected during a 10-year storm. Larger storms overload them, and the resulting backed-up sewers and overloaded ditches produce shallow flooding. Another urban drainage problem occurs in the areas protected by levees. Being in floodplains, they are flat and do not drain naturally, especially when a levee blocks the flow to the river. To drain these areas, channels have been built and pumps installed to mechanically move the water past the levee. Often, these man-made systems do not have the capacity to handle heavy rains or intense storms.

Another challenge with stormwater infrastructure is related to recordkeeping. It is not uncommon for stormwater data to be incomplete in most jurisdictions and completely lacking in others. Quality of data differs from jurisdiction to jurisdiction; some are in GIS formats, while others are paper maps or as-builts that represent the infrastructure at a macroscale level. The condition of the assets may be lacking, and the maintenance history may not be available either. Stormwater assets may have been installed with no records, especially in rural areas, farm fields, and private property.

Walton County passed Ordinance No. 2008-06 that prohibits unauthorized discharges into storm drains or ditch systems. In addition, the Public Works Division is currently running a continuous public awareness campaign aimed at encouraging the adoption of best management practices (BMPs) for managing stormwater runoff. This initiative targets both the business community and the residents of Walton County.

To address the issue of flooding, Walton County has implemented several measures along the years, such as:

- Drainage Systems: The county has invested in the development and maintenance of drainage systems, including ditches, canals, and retention ponds, to manage stormwater runoff and reduce flood risk.
- Floodplain Management: Walton County has adopted floodplain management regulations and participates in the National Flood Insurance Program (NFIP) to encourage responsible development in flood-prone areas.
- Elevation Standards: New construction projects within flood zones are required to adhere to specific elevation standards to minimize potential flood damage.
- Emergency Response: The county has established emergency response plans to assist residents during flood events, including evacuation procedures and the provision of emergency shelters.

Key stormwater assets for the HUC and Walton County are indicated in **Error! Reference source not found.** and **Error! Reference source not found.**, respectively. Stormwater structures and management processes in the county consist of stormwater outfall, water wells, weir, pollutant control boxes, inlets catch basins, pipes culverts, ditch conveyance swales, structures, pipes and open conveyance.

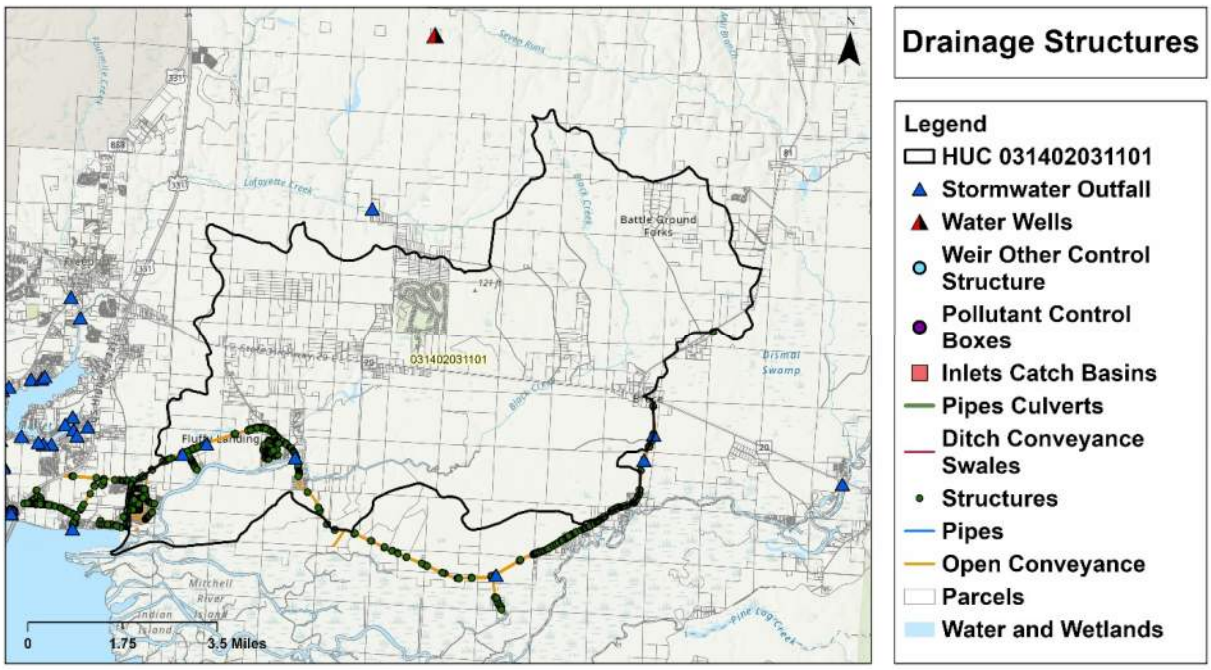

Figure 27. Stormwater Infrastructure for the HUC 031402031101. Processed by FAU.
(Source Data: Walton County Storm Asset Inventory and Stormwater Inventory)

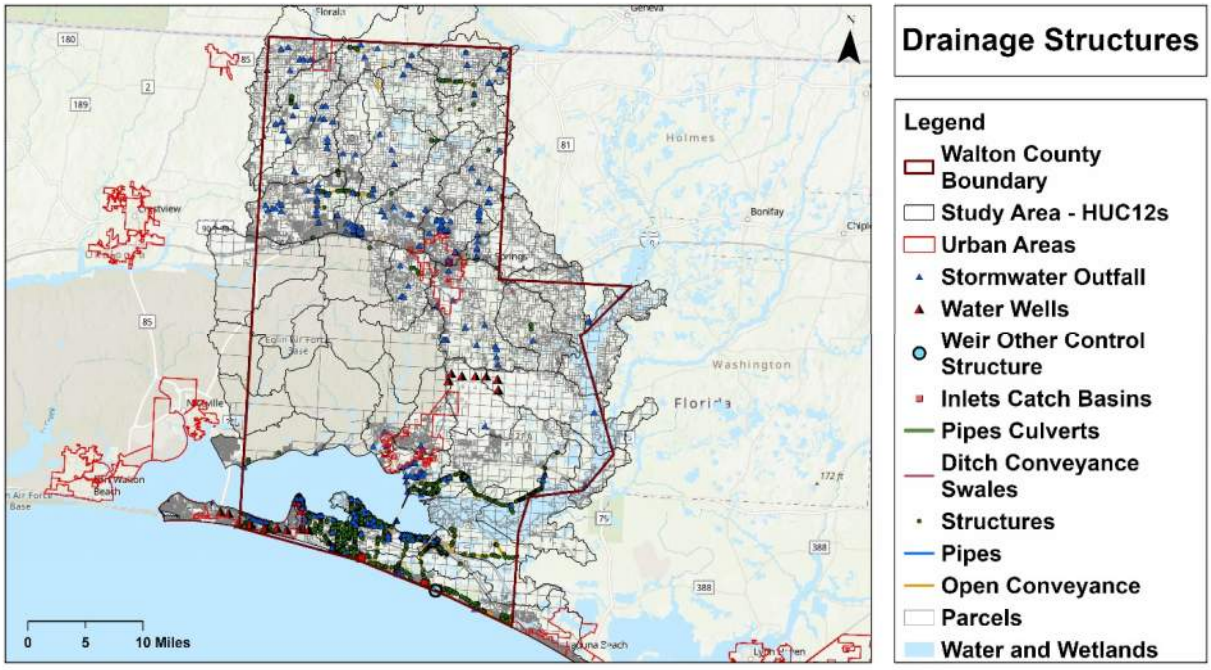

Figure 28.Stormwater Infrastructure for Walton County. Processed by FAU.
(Source Data: Walton County Storm Asset Inventory and Stormwater Inventory)

Although nature-based infrastructure might be installed, it is not certain. The stormwater system must maintain compliance with the stormwater regulations, which requires record-keeping, policy development, inspections and maintenance. The goals of such stormwater management may include:

- Best landscape practice;
- Control car washing contribution to pollution;
- Enforce the Stormwater Pollution Prevention Plan (SWPPP) by site evaluation, assessment, erosion and sediment controls, preventive maintenance, certification and inspection reporting for construction sites and city planning;
- Implement a hazardous material elimination system;
- Eliminate illicit dumping;
- Proactive and reactive catch basin inspections and maintenance;
- Street sweeping to control debris;
- Maintain swales to help prevent stormwater pollution flooding.

1.13 Data Gaps

FAU has developed comprehensive databases to address the information needed for the vulnerability assessment. These are included in Table 5. The data can be used to model the impacts

of flood routing during the storm of interest. As a result, the modeling pieces (discussed in Chapter 2) will include the following:

- Flood response model results (Cascade 2001)
- Flood risk/hazard mapping
- Vulnerability assessments to identify areas of concern for future repetitive losses

There is only one data gap for the area – existing stormwater infrastructure records are incomplete. However, for the purposes of this plan, this data gap does not limit the findings as there are two scales: 1) the sub-watershed level and 2) community hotspots. A neighborhood level vulnerability assessment will require the local infrastructure inventory.

Table 6. List of datasets collected by FAU as of List of datasets collected by FAU for the project (12/20/2020)

2.0 ASSESSMENT OF VULNERABLE AREAS

Defining flood risk due to compounding hydrographic influences is the central concern of this WMP. Modeling and assessment of vulnerability focused on the combination of a high-water table, heavy rains, and impervious conditions that can lead to localized nuisance flooding events. Through a previous survey with local officials, the number of days of continuous nuisance flooding that the public will tolerate before that flooding is considered destructive is about 4 days (E Science 2014).

For a large study area, small parts may actually be at risk. The point is to identify where further study might be needed. A screening tool accomplishes this goal applied to the sub-watershed scale to designate areas that are susceptible to periodic flooding events. Utilizing the information collected and analyzed in Chapters 1, analysis of flood vulnerability can be performed.

2.1 Historical and Existing Challenges

Walton County has faced various historical and existing challenges as well as natural hazards over the years. Some of these include:

- Hurricane and Tropical Storms: being situated along the Gulf Coast, Walton County is vulnerable to hurricanes and tropical storms, which can lead to damage to the built and natural environment, as well as poses risks to human and wild life.
- Coastal Erosion: The county's coastline is subject to erosion due to natural processes and human activities. Erosion can lead to the loss of beaches and threaten coastal structures and properties.
- Flooding: heavy rainfall, storm surges from hurricanes, and other factors can cause localized flooding, particularly in low-lying areas. Flood events can disrupt daily life, damage property, and impact transportation.
- Water Quality and Quantity: as in many coastal areas, managing water quality and maintaining an adequate water supply are ongoing challenges. Pollution from stormwater runoff and other sources can affect water quality, and groundwater resources need to be carefully managed to sustain the growing population.
- Wetland Loss: The county's wetlands face the threat of degradation and loss due to urban development and other human activities. Protecting these essential ecosystems is vital for maintaining biodiversity and mitigating flood risks.
- Urbanization and Development: Balancing the demand for development and growth with the preservation of natural habitats and resources is a persistent challenge. Unplanned

urbanization can lead to habitat destruction, increased runoff, and exacerbate flooding risks.

- Land Use and Zoning: Proper land use planning and zoning are essential to address issues related to population growth, infrastructure development, and natural hazard mitigation. Ensuring responsible development practices can help minimize risks.
- Invasive Species: Like many regions, Walton County faces the threat of invasive plant and animal species. These invasive species can disrupt local ecosystems, negatively impacting native flora and fauna.
- Sea-Level Rise: With rising sea levels due to climate change, coastal communities like Walton County's coastal areas are at greater risk of inundation and storm surges during extreme weather events.

The fast growth of the population and urban development in the coastal areas of the county exacerbates effort to protect open space for land percolation of water. While regulations are in place to reduce the influx of stormwater, the challenges will continue with development.

2.1.1 Existing Management Efforts in the Watershed

The county is under Northwest Florida Management District (NWFMWD) jurisdiction, which covers the Florida Panhandle region. The NWFMWD is responsible for managing and protecting water resources in its designated regions, which includes issues related to water supply, water quality, flood control, and natural resource conservation. Local governments have local stormwater utility infrastructure and planning/policy tools to reduce future flood potential. Most of the major projects to date have been focused on addressing the water quality issues and flooding due to extreme rainfall.

2.1.2 Critical Target Areas Identification

By modeling the HUC 031402031101 sub-watershed flood response to a series of rainfall events and sea levels (plus king tides), and further classifying flood risk as the probability of inundation, it is possible to identify critical target areas. These areas are particularly vulnerable to flooding and are subject to further study through a scaled-down modeling approach. The screening tool is first applied at the greater watershed level to provide an initial risk assessment focused on the hydrologic response to a rainfall event given the unique characteristics and features of the sub-watershed or study area. The process is discussed later in Section 2.2 with results presented in Section 2.4.

2.1.3 Potential Preservation Areas

Walton County boasts several areas with high biodiversity value. These areas include the unique coastal dune lakes, which support diverse ecosystems and contribute to water quality along the coast. Wetlands are crucial habitats that provide refuge for a variety of plant and animal species while acting as natural water filters. State parks like Topsail Hill Preserve and Grayton Beach State Park are valuable conservation areas with diverse coastal ecosystems. Additionally, preserving the Choctawhatchee River Basin is essential for the biodiversity of the region.

2.2 Vulnerability Maps

2.2.1 Screening Tool

The screening tool utilizes topographic data from various sources (Section 1.1), water table elevations (Section 1.2) and surface water gauges (Section 1.3) downloaded from the NWFWMD website, tidal information for coastal areas obtained from the NOAA Current & Tides website (Section 1.3), soil maps obtained from the USDA (Section 1.4), and another key dataset as described previously in Chapter 1. The design storms are discussed in Section 1.6. The reason this is critical is that to do any modeling (as required by the CRS program), a screening tool should be used to identify regions with a high risk of inundation based on multiple collected datasets and hydrological models. **Error! Reference source not found.** shows how the GIS layers interface in the tool and how they are combined for spatial analysis.

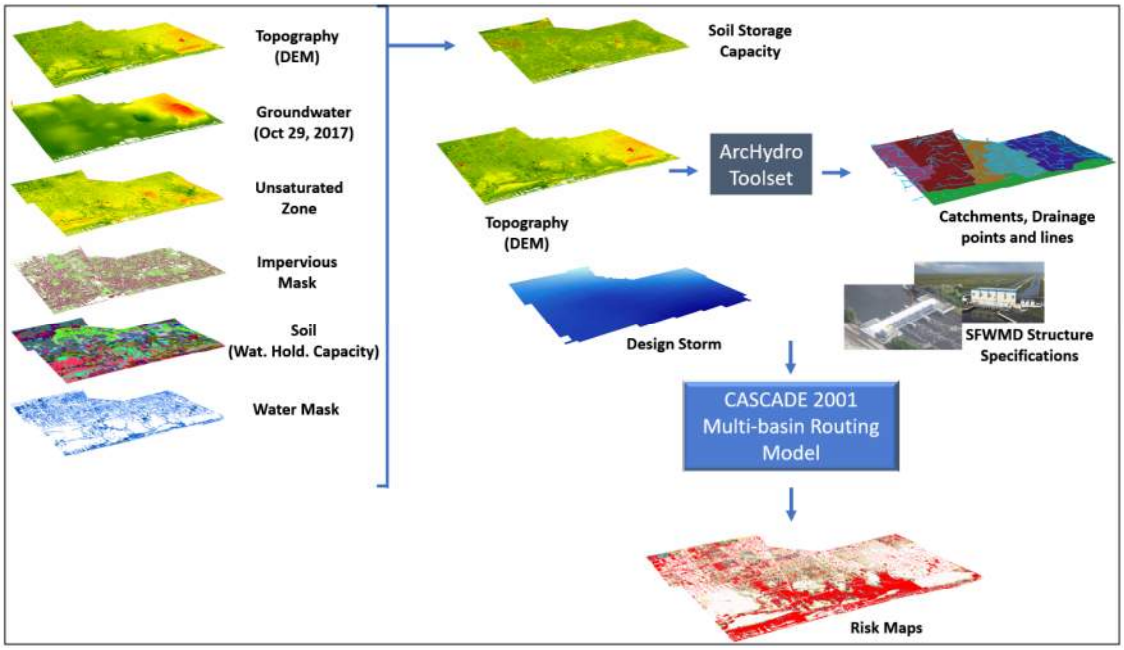

Figure 29. Screening tool methodology for creating flood risk maps

The model chosen for this screening tool is Cascade 2001, which is a multi-basin hydrologic/hydraulic routing model developed by the SFWMD. The model permits the investigator to run different storm events to determine flooding scenarios. The boundaries are critical for basin studies and must be chosen carefully. The following data layers collected in the prior section are processed to develop the input files for Cascade 2001:

- Topography
- Soils
- Development intensity
- Groundwater elevations
- Surface water/Outlet locations

The software creates a glass box where water rises to a certain level and then decreases. Running the simulation requires defining the basin (HUC or sub-HUC) and input of the following data:

- Area
- Portion of area above a given elevation
- Initial groundwater stage
- Longest travel time for the runoff to reach the most distance point of discharge
- Ground storage as estimated from the USDA gridded National Soil Survey Geographic Database (gNATSGO)

  Ground storage ≈ (Water holding capacity) × (Surface elevation – GW elevation)

= 2 × (AWS for a soil layer of 0-150 cm) / 150cm × (Surface elevation – GW elevation)

- Available water storage (AWS) for a soil layer of 0-150 cm
- Average amount of precipitation that can be stored in the soil layer

The output from the model is an elevation surface that can be used to develop a flood map for the study area (Figure 30), which shows the spatial distribution of probabilities of flooding during the modeled 1-day 100-year storm event.

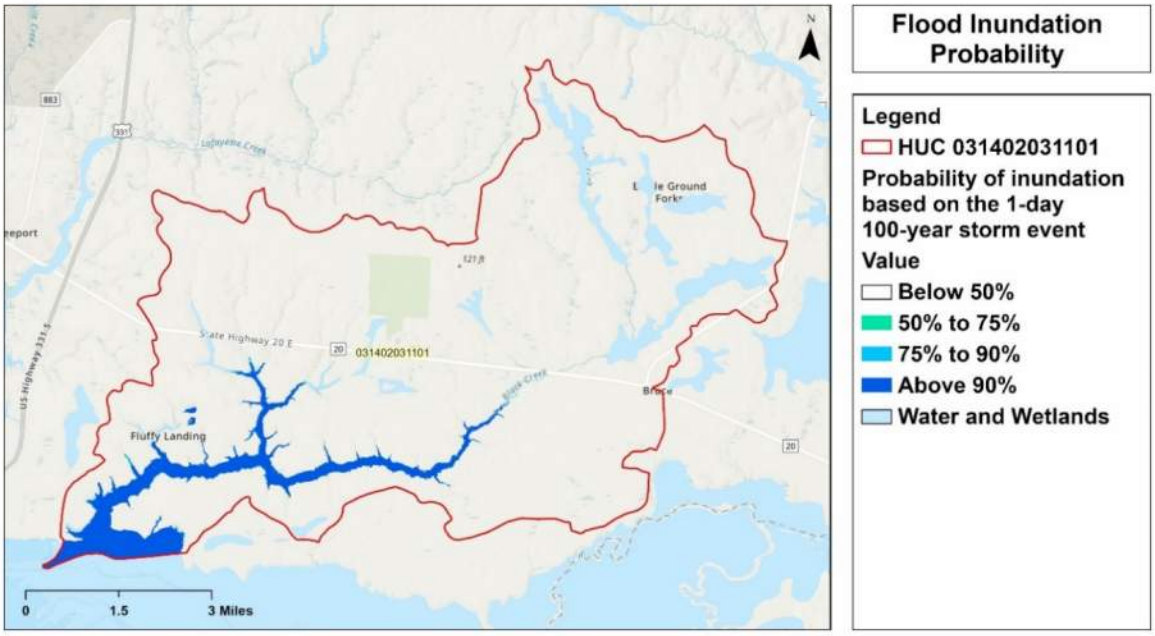

Figure 30. Probability of flood risk map during the modeled 1-day 100-year storm event for the HUC 031402031101, processed by FAU.

2.2.2 Identification of Vulnerable Areas

Given these assumptions and the Cascade 2001 outputs, the goal of this methodology is to produce a spatially-temporally quantified understanding of nuisance-destructive flood potential in the study area given observed values. Risk is a function of compounding geo-hydrological features, namely, surface water, groundwater, topography, build-out, and time of year. A GIS-based algorithm and spatial interpolation generated layers of the greatest observable hydrographic surfaces. These outputs were then compared with high resolution topographic LiDAR data to develop digital elevation models that reflect the observed risk landscape. These models can then be combined into Cascade 2001 to produce vector and volume information, in combination with soils, vegetation

and impervious surfaces, allowing the observed model outputs to be extrapolated into a more predictive context.

To evaluate flood vulnerability at this scale, the analysis starts with a binary flooding surface (0 = below 50% chance of flooding; 1 = above 50% flooding) based on output from the screening tool for a specified design storm. Next, attributes of that raster based on "VALUE = 1" query are extracted using *Extract by Attributes* tool. Then the *Batch Project* tool was used to map critical facilities data to the common coordinate system (NAD83 UTM Zone 17N), unit = meters. Then a field was added using *Add Field* for [PriorityTier] = assigned Tier #1-4 value from the DOR codes and [Area_sqmeter]. The critical facilities layers were then merged into a single layer to calculate the polygon geometry for [Area_sqmeter] using the *Merge* tool. Next, *Zonal Statistics as Table* is used to calculate the SUM of flooded values ("VALUE = 1") within each critical parcel. Output table has fields for SUM (i.e., total # of flooded pixels per critical parcel) and AREA in map units of square meters (since each pixel in the flooding surface has a cell size of 3-meters by 3-meters, each area is equal to the SUM value multiplied by 9 m^2). Using the *Join Field* tool, the SUM and AREA fields are joined to the merged critical facilities layer based on a key attribute, first renaming these fields for clarity (e.g., AREA_FLOODED_3d25y). Once all field data is included, the next step involves using *Export Table* to export the dataset as a CSV file. Note that non-flooded parcels have zero flooded area, so they receive a <Null> value from the zonal statistics tool. To replace null values with zeros, we use *Calculate Field* in the attribute table along with the following Python expression (replacing the respective field name): "0 if !AREA_FLOODED_3d25y! is None else !AREA_FLOODED_3d25y!". Next, the CSV file is saved as an Excel Workbook (.xlsx). The Range is converted to an Excel table, and the columns are rearranged in the desired order. Finally, the "percent-flooded" columns are calculated as follows:

- PCT_FLOODED_3d25y = ([@[AREA_FLOODED_3d25y]]/[@[TotalArea_sqmeter]])*100
- PCT_FLOODED_1d100y = ([@[AREA_FLOODED_1d100y]]/[@[TotalArea_sqmeter]])*100

After this calculation, the table is sorted to show the higher priority tiers and higher percent-flooded values first. To reduce the number of critical facilities shown in the final table, a filter was created to show only critical facilities with 10% or more flooded area in the parcel during both storm events. Records with duplicate parcel ID numbers were removed from the table. The results of this procedure are discussed in Section 2.5 of this document.

With respect to dams and levees, for purposes of the NFIP, FEMA only recognizes systems that meet, and continue to meet, minimum design, operation, and maintenance standards that are consistent with comprehensive floodplain management criteria. The Code of Federal Regulations,

Title 44, Section 65.10 (44 CFR 65.10) describes the information needed for FEMA to determine if a levee system reduces the risk from the 1% annual chance flood. FEMA has accredited levees and Provisionally Accredited Levees (that have a specified timeframe to obtain the necessary data to confirm the levee's certification status). If a levee system no longer meets Section 65.10, FEMA will de-accredit the levee system and issue an effective FIRM showing the levee-impacted area as a SFHA. FEMA coordinates its programs with USACE, who may inspect, maintain, and repair levee systems. USACE has authority under Public Law 84-99 to supplement local efforts to repair flood control projects that are damaged by floods. Like FEMA, USACE provides a program to allow public sponsors or operators to address levee system maintenance deficiencies. Failure to do so within the required timeframe results in the levee system being placed in an inactive status in the USACE Rehabilitation and Inspection Program. Levee systems in an inactive status are not eligible for rehabilitation assistance under Public Law 84-99. There are no levees/dams listed in the sub-watershed study area.

2.3 Future Challenges of Sea Level Rise and Climate Change

Global observations from satellites and long-term data collection have made it possible to document and analyze patterns in the Earth's climate. Scientific analysis of the impact of these changes has helped to improve the understanding of future flood hazard driving forces and long-term impacts on human activities and watershed master planning (http://www.research.noaa.gov/climate/t_observing.html). Examples of impacts are rising global average air and ocean temperatures, increased and earlier snow and ice melt, shorter subtropical rainy seasons, shifted seasons, sea level rise and greater variations in temperature and precipitation (IPCC, 2013; Freas et al., 2008; Marshall et al., 2004; Bloetscher et al., 2010). Marshall et al. (2004) specifically focused on the Florida peninsula to predict changes in rainfall and warmer temperatures but interspersed lower low temperatures due to the potential loss of wetlands.

Future changes in climate will add to the existing impacts, at a time when the population of the state is expected to nearly double by 2030. Additional research and high-resolution climate modeling for the Florida peninsula and local jurisdictions is needed to help guide long-term plans like WMPs. Rainfall appears to be decreasing and temperatures rising (see **Error! Reference source not found.**).

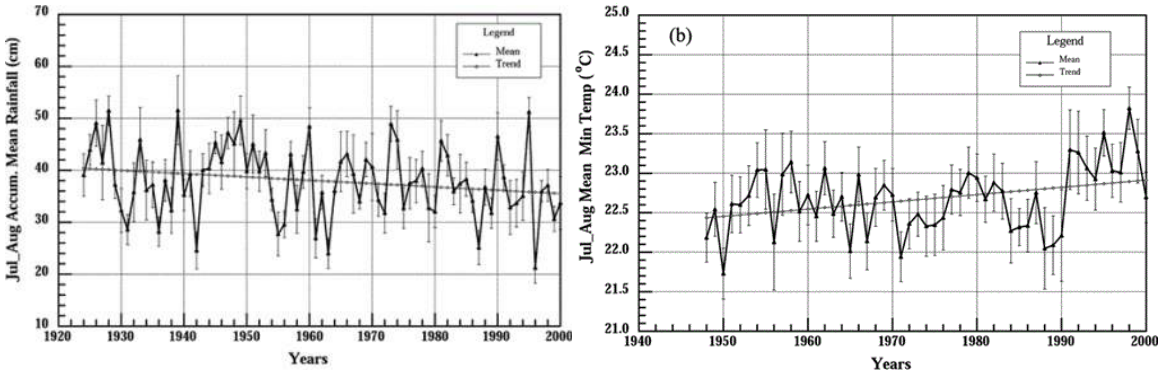

Figure 31. Change in average rainfall and change in average temp 1924 to 2000.
Note the reversed trend, which means groundwater input variability is lessened.
(Source: Marshall et al., 2004)

Climate change is likely to: 1) threaten the integrity and availability of fresh water supplies and 2) increase the risk of flooding, not only in the low-lying coastal areas, but also in the interior flood plains. Other issues include a) saltwater intrusion, which may be intensified by sea level rise, b) prolonged droughts that will contribute to water supply shortages and wildfires, and c) heavier rains during the rainy season and higher hurricane storm surge, which may increase the risk due to flooding. More frequent and damaging floods are likely to become an ever-increasing problem as sea level continues to rise because of: a) increasing groundwater table elevations and surface water gage heights, b) reduced groundwater seepage through the aquifer to the ocean, c) increasingly compromised stormwater drainage systems, and d) more frequent inundation of barrier islands and coastal areas.

NOAA and IPCC (2013) predictions suggest that by 2100, global temperatures will be on the order of 2-3°C (3-5°F) higher and sea levels will rise by up to 3 feet. Accompanying these drivers are potential changes in storm frequency and intensity, desertification, population migration, ocean acidification and coastal flooding (IPCC, 2007), exacerbated by the land cover and land use changes, which are substantially impacted by the fluxes, timing and quality of precipitation (Adrians et al., 2003; Scanlon et al., 2005; Marshall et al., 2004; Salmun and Molod, 2006), and leading to changes in the timing of peak flows and volumes (Richey and Costa-Cabral, 2006).

The results of these climatic changes are likely to: 1) threaten the integrity and availability of fresh water supplies and 2) increase the risk of flooding, not only in the low-lying coastal areas, but also in the interior flood plains. Other issues include a) saltwater intrusion, which may be intensified by sea level rise, b) prolonged droughts that will contribute to water supply shortages and wildfires, and c) heavier rains during the rainy season and higher hurricane storm surge, which may increase the risk due to flooding. More frequent and damaging floods are likely to become an ever-increasing problem as sea level continues to rise because of: a) increasing groundwater table elevations and surface water gage heights, b) reduced groundwater seepage through the aquifer to

the ocean, c) increasingly An outcome of these climatic patterns is that during the past 140 years, an increase in sea levels has been observed (Bloetscher, 2012), a worrying pattern since sea level rise is a permanent phenomenon, that can be catastrophic to low lying areas in the long-term. The question is how much and how soon? Various studies (Bindoff et al., 2007; Domingues et al., 2008; Edwards, 2007; Gregory, 2008; Vermeer and Rahmstorf, 2009; Jevrejeva, Moore and Grinsted, 2010; Bloetscher, 2010, 2011; IPCC, 2007; Heimlich et al., 2009) indicate large uncertainty in projections of sea level rise by 2100. Gregory et al. (2012) note that during the last two decades, the global rate of sea level rise has been larger than the 20th-century time-mean, and Church et al. (2011) suggested that the cause was increased rates of thermal expansion, glacier mass loss, and ice discharge from icesheets. Gregory et al. (2012) suggested that there may also be increasing contributions to global sea level rise from the effects of groundwater depletion, reservoir impoundment, and loss of storage capacity in surface waters due to siltation. Measurements of Florida's east coast (Maul, 2008) show an average rate of sea level rise of 2.27 ± 0.04 mm per year from 1915 to 1992 based on tide gauge readings. Analyzing the tidal gauge readings for Florida shows that:

1. Florida average sea level rise is 2.10 ± 0.49 mm/yr
2. All but one location is within the 95% confidence limit range (the exception is Panama City where there is evidence of submergence and other land-based issues)
3. None of the Florida sea level rise rates differ statistically
4. Average global sea level rise for 1920-2000 was 2.0 mm/yr – within 95% confidence limit for Florida locations

From 1929 to 1992, over eight inches of sea, with another 6 inches added since 1992, which is already having significant impacts on coastal communities where population growth has increased the need for improved flood management strategies (Bloetscher, 2008; Parkinson, 2010; Zhang et al., 2011, 2011a; NFIP, 2011; Schmidt et al., 2011; Warner et al., 2012).

As a result, the SFRCCC (2015) adopted USACE's methodology to derive scenarios of sea level change intermediate to high rates of sea level rise for years 2030 (3" to 7") and 2060 (9" to 24") as the consensus projection to guide future planning. The path keeps increasing – now 14 inches since 1929 (**Error! Reference source not found.**) caused by thermal expansion of the ocean and melting ice caps (Jevrejeva et al., 2010; Vermeer and Rahmstorf, 2009). Sea level rise is a major concern in Florida, including Walton County, since the majority of the state's population live on the coast, involving most major commercial, residential, and economic enterprises. **Error! Reference source not found.** demonstrate the estimated sea level change for Panama City, considering the predictions of NOAA 2017. For NOAA high scenario SLR change scenario, the estimated level change is higher than 8 ft., while for the intermediate and low scenarios are about 3.9 feet and 1.7 feet respectively.

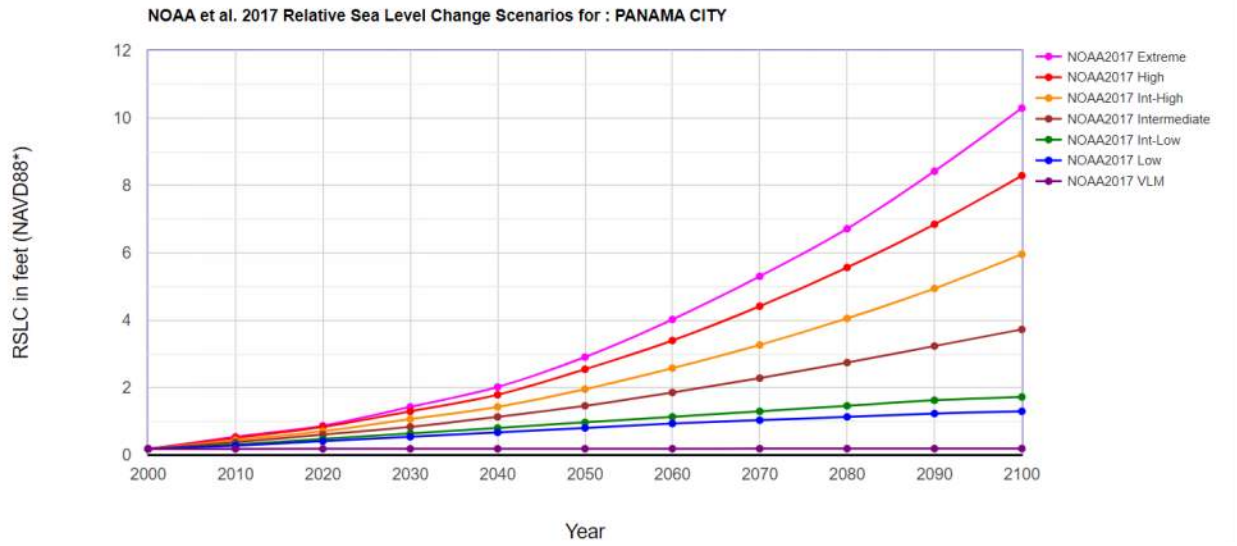

Figure 32. Relative Sea Level Change Scenarios for gauge 8729108, Panama City, FL. (Source: NOAA, 2017 available at https://cwbi-app.sec.usace.army.mil/rccslc/slcc_calc.html)

NOAA (2017) outlines five scenarios for sea level rise. The NFIP proposes the use of the intermediate high projection, which is 1.2 meters or 4 ft globally from current sea level elevations (**Error! Reference source not found.**).

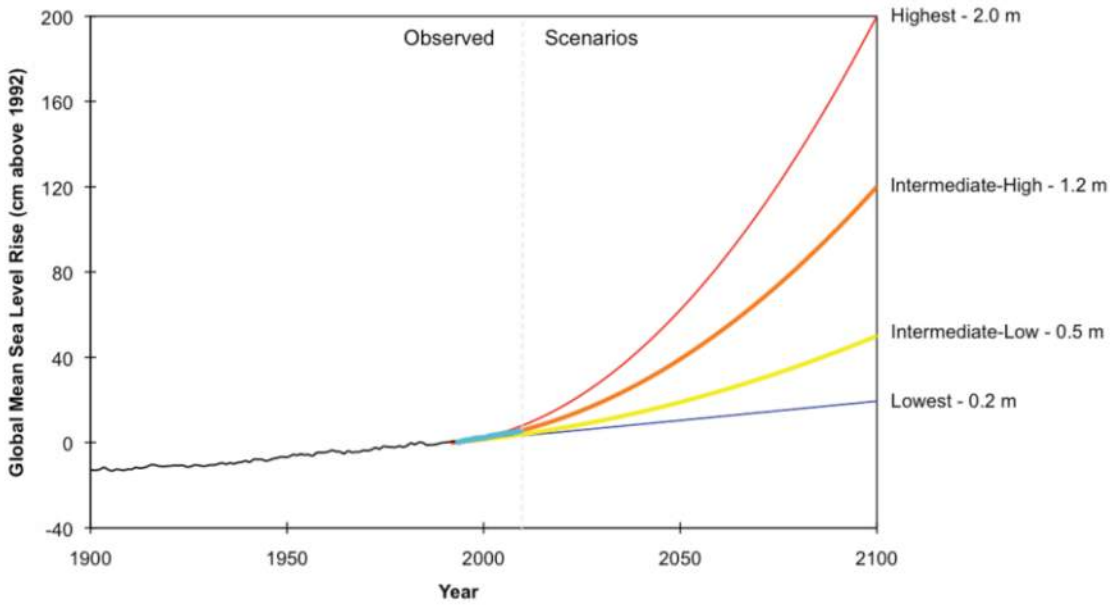

Figure 33. Graphic of global sea level rise projections from NOAA (2017). (Source: NOAA, 2017 available at https://tidesandcurrents.noaa.gov/publications/techrpt83_Global_and_Regional_SLR_Scenarios_for_the_US_final.pdf)

As sea level rises, access to roads, bridges, rail, and transit could be at risk of flooding, causing the effects of sea level rise to spread indirectly throughout the entire transportation network, affecting the overall system performance. For example, the flooding of a critical road or facility access can cause a shifting of traffic flow causing congested conditions in other roadways that are not actually flooded. Since the roadway network would be unable to carry the traffic demand, the system would experience operational failure; as a result, causing travel times and delays. Moreover, the inundation of a critical access could cause transportation connectivity problems to essential infrastructure like ports or airports. Transportation infrastructure relies on the effectiveness of flood control and stormwater drainage systems for the transportation corridors. Road integrity relies on adequate drainage. The increased risk of severe flooding in Florida's low-lying terrain can adversely affect transportation infrastructure along the coastline; roads can be inundated, and roadway beds can be damaged. Sea level rise will cause increased water Table levels (FDOT, 2012), as regional water tables cannot exist naturally below mean high tide (2 feet in Florida). Adding 3 feet of sea level rise on top of groundwater would compound the risk of flooding in low-lying areas. Road bases below 5 feet NVGD would become saturated under this scenario, likely causing premature base failure. As soil storage capacity is diminished due to rising groundwater elevations associated with sea level rise, the potential for more frequently flooded roadways would likely damage pavements (FDOT, 2012). Hence sea level rise must be accounted for in WMPs in coastal areas. To allow flexibility in the analysis due to the range of increases within the different time periods, an approach that uses incremental increases of 1, 2, and 3 feet of sea level rise is suggested for modeling. The increments can work as threshold values in planning considerations in terms of allowing planners the ability to know ahead of time where the next set of vulnerable areas will be, to allow for a proactive response approach that can be matched to the observed future rates. Sea level rise is a major concern since nearly half the US population lives within 50 miles of the coast, involving most major commercial, residential, and economic enterprises. The effects of 5 ft sea level rise, King tide, and 1-day 100-year storm event are shown in Figure 34.

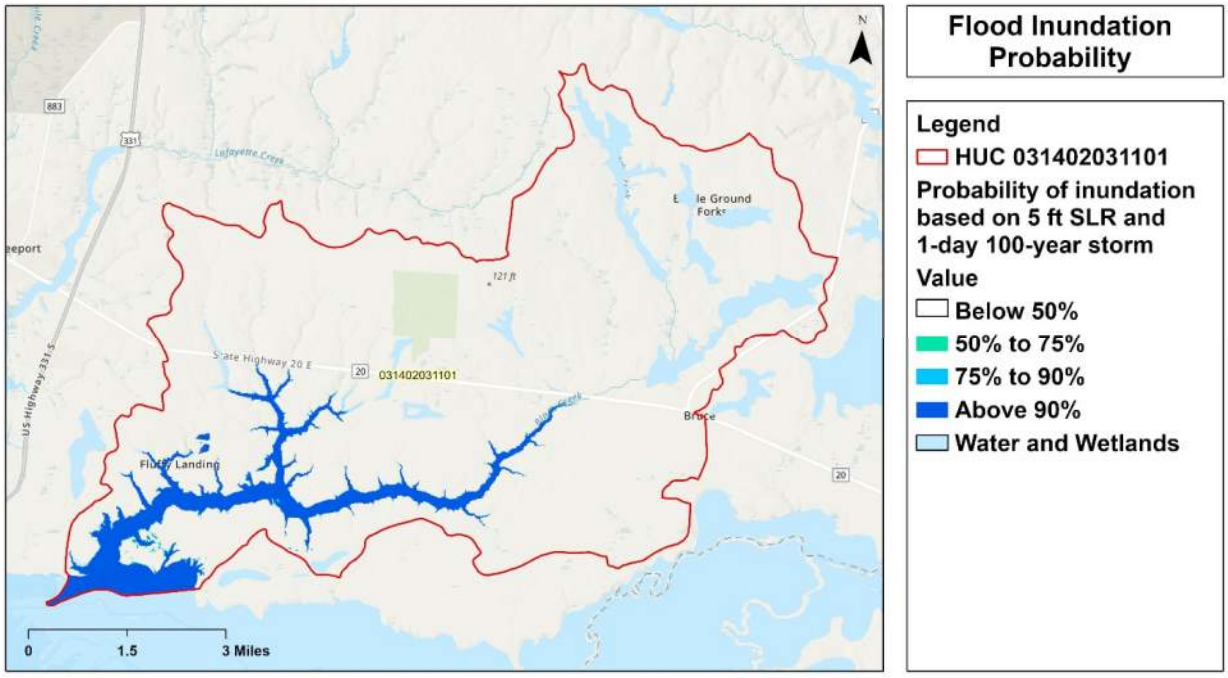

Figure 34. Flood Inundation Probability for a Sea level rise of 5 ft + 1-day 100-year storm event for HUC 031402031101 sub-watershed. Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations. Dark blue is area under 5 ft NAVD8

2.4 Modeling Results

Error! Reference source not found. to **Error! Reference source not found.** are a series of maps that depict risk of flooding in the basin based on the following scenarios:

1. **3-day 25-year storm event**. Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 35)
2. **1-day 100-year storm event**. Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 36)
3. **1-day 10-year storm event.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 37)
4. **1-day 5-year storm event.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 38)
5. **Sea level rise of 1 ft + 3-day 25-year storm** (only coastal area and GW affected – GW layer rises 1 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 39)
6. **Sea level rise of 1 ft + 1-day 100-year storm** (only coastal area and GW affected – GW layer rises 1 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations storm (Figure 40)

7. **Sea level rise of 1 ft + 1-day 10-year storm** (only coastal area and GW affected – GW layer rises 1 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 41)
8. **Sea level rise of 1 ft + 1-day 5-year storm** (only coastal area and GW affected – GW layer rises 1 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 42)
9. **Sea level rise of 2 ft + 3-day 25-year storm** (only coastal area and GW affected – GW layer rises 2 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 43)
10. **Sea level rise of 2 ft + 1-day 100-year storm** (only coastal area and GW affected – GW layer rises 2 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 44)
11. **Sea level rise of 2 ft + 1-day 10-year storm** (only coastal area and GW affected – GW layer rises 2 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 45)
12. **Sea level rise of 2 ft + 1-day 5-year storm** (only coastal area and GW affected – GW layer rises 2 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 46)
13. **Sea level rise of 3 ft + 3-day 25-year storm** (only coastal area and GW affected – GW layer rises 3 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 47)
14. **Sea level rise of 3 ft + 1-day 100-year storm** (only coastal area and GW affected – GW layer rises 3 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 48)
15. **Sea level rise of 3 ft + 1-day 10-year storm** (only coastal area and GW affected – GW layer rises 3 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 49)
16. **Sea level rise of 3 ft + 1-day 5-year storm** (only coastal area and GW affected – GW layer rises 3 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 50)
17. **Sea level rise of 4 ft + 3-day 25-year storm** (only coastal area and GW affected – GW layer rises 4 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 51)
18. **Sea level rise of 4 ft + 1-day 100-year storm** (only coastal area and GW affected – GW layer rises 4 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 52)
19. **Sea level rise of 4 ft + 1-day 10-year storm** (only coastal area and GW affected – GW layer rises 4 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 53)

20. **Sea level rise of 4 ft + 1-day 5-year storm** (only coastal area and GW affected – GW layer rises 4 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 54)
21. **Sea level rise of 5 ft + 3-day 25-year storm** (only coastal area and GW affected – GW layer rises 5 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 55)
22. **Sea level rise of 5 ft + 1-day 100-year storm** (only coastal area and GW affected – GW layer rises 5 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 56)
23. **Sea level rise of 5 ft + 1-day 10-year storm** (only coastal area and GW affected – GW layer rises 5 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 57)
24. **Sea level rise of 5 ft + 1-day 5-year storm** (only coastal area and GW affected – GW layer rises 5 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 58)

In all scenarios, a considerable amount of flooding is noted at the river entrance to the HUC, extending to the wetland areas. As this basin connects to the ocean though Choctawhatchee Bay, SLR scenarios plays an important hole, implying a considered growth as the projected scenario of rising tides rises.

The design storm simulation determined that approximately 4.9% of the HUC total area or 2.53 mi² has a probability of inundation above 50% for a 3-day 25-year design storm. For comparison, approximately 5% of the HUC's total area, or 2.58 mi² would be expected to be inundated during a 1-day 100-year design storm. Approximately 4.7% of the HUC's total area, or 2.43 mi², would be expected to be inundated during a 1-day 10-year design storm. Finally, approximately 4.6% of the HUC's total area, or 2.38 mi², would be expected to be inundated during the 1-day 5-year storm. **Error! Reference source not found.** compares the four storm events.

Table 7. HUC 031402031101 expected inundated area by storm event.

Storm Event	Area with probability of inundation below 50% (Sq Mi)	Area with probability of inundation above 50% (Sq Mi)	Area with probability of inundation below 50% (%)	Area with probability of inundation above 50% (%)
3-day 25-year	49.45	2.53	95.1%	4.9%
1-day 100-year	49.40	2.58	95.0%	5.0%
1-day 10-year	49.55	2.43	95.3%	4.7%
1-day 5-year	49.60	2.38	95.4%	4.6%

2.5 Risk and Vulnerability

The screening tool modeling exercise from the prior section identified areas within the communities that are vulnerable to flooding. Higher priority concerns should be those properties or assets that are considered essential and need to be kept in service during a flooding event. All other improvements are local. To help with prioritization, the following is suggested:

- Tier 1 - Critical facility protection (water/sewer utilities, public safety, hospitals, schools, power, shelters)
- Tier 2 - Essential facilities (groceries, pharmacies, roadways)
- Tier 3 - Economic centers (protecting jobs)
- Tier 4 - At risk communities
- Tier 5 - Other urban/suburban property
- Tier 6 - Agriculture/public property/vacant/undeveloped

Error! Reference source not found. outlines the priority of land use based on DOR land use codes from the property appraiser's office and assigns an associated priority level to each parcel. Note that for residential property, identifying at-risk communities (income, age, disability, health)

requires a further drilldown to the neighborhood level (i.e. wealthy neighborhoods with few older, poor health individuals would have a lower priority than at risk communities, which generally have lower value housing and denser development). In the latter case, more people are impacted, and those people have less ability to mitigate risk. Based on these priorities, the relative risk priority DOR land use codes were evaluated based on a scale of 1 to 6, where 1 is higher priority (more vulnerable) and 6 is the least priority (least vulnerable).

Table 8. Priority of Land Use based on (DOR) land use codes. Processed by FAU.

DOR (Use code)	**Description**	**TIER (Priority of Land Use)**
0	Vacant Residential	6
1	Single Family Residential	5

99	Other Non-Agricultural Acreage	6
100	Parcel With no Values	6

101	Parcels With no Values (ROW - avenues, highways, arterials)	2
102	Parcels With no Values (Water)	6
103	Parcels With no Values (Rail)	2

Having assigned the risk priority from 1 to 6 in the DOR codes and the percentage of the parcel that floods during the applicable design storm, properties that are more critical to the function of the community can be identified. The methodology is to first convert the DOR code priority tier to its inverse scale by the following equation:

Consequence of risk factor = 7 – DOR Code Priority Tier

The flood risk factor from the screening tool is interpreted based on flooding probability. We take all parcels in tiers #1-4 that have a greater than 50% chance of flooding during a particular design storm and calculate the percent of the parcel that would flood during that event. The percentage is converted to a 6-point scale termed as the Flood Risk Factor, shown in **Error! Reference source not found.**.

Table 9. Flood Risk Factor Classification.

Percent of Parcel Flooded	Flood Risk Factor
90-100%	6
80-89%	5
70-79%	4
60-69%	3
50-59%	2
<50%	1

The priority is further developed by assigning 75% of the importance to the consequence of flooding and 25% importance to flood risk, or three times the importance to the consequence of flooding to come up with a composite score as follows:

Flood Risk Factor × 25% + Consequence of Risk Factor × 75% = Composite Score

Example: 1 × 25% + 6 × 75% = 4.75

Those higher priority properties that received the higher composite score are where the mitigation strategies and financial resources should focus first.

2.5.1 Results

The first map (**Error! Reference source not found.**) exclusively displays critical facility parcels within the HUC without any flooding. The second map (Figure 60) overlays critical facilities onto the 1-day 100-year storm event scenario, while the third map (**Error! Reference source not found.**) represents the same overlay within the context of 5 feet of sea level rise (SLR) combined with the 1-day 100-year storm event. **Error! Reference source not found.** is a mosaic showing critical facilities overlaid in the 5 feet SLR + 1-day 100-year storm event for the whole county.

Additionally, **Error! Reference source not found.** and **Error! Reference source not found.** illustrate the composite score for the HUC, which is the result of the calculations explained above, pinpointing parcels that should be prioritized. It considers only parcels classified as 1 to 4 tiers, and within the 50% probability of inundation area. **Error! Reference source not found.** represents the calculation for composite score based on 1-day 100-year storm event, while **Error! Reference source not found.** shows the calculation for composite score for the same storm event, but including a 5 feet of Sea Level Rise scenario. **Error! Reference source not found.** shows the same area zoomed out.

Please note that the composite score results display outcomes exclusively for parcels within the flooding path area. Consequently, for parcels outside this flooding path, the composite results will be null. The composite score combines the flooding path area with the land use priority results to identify the most vulnerable areas deserving of priority.

2.5.2 Solutions

Chapter 5 of the Watershed Master Plan for Walton County describes a list of possible gray and green stormwater strategies to combat flooding that can be implemented as solutions for the county. The same solutions can also be applied at the HUC level, including HUC 031402031101. A summary of these flood mitigation strategies is listed in **Error! Reference source not found.**. For more detailed information, please see Chapter 5-5.3 (Solutions).

Table 10. List of possible gray and green stormwater strategies to combat flooding

Strategy Class	Implementation Strategy	Applications	Benefits	Cost	Barriers to Implementation
Green	Rainwater harvesting	Local, small scale, easily implemented in developed areas	Protects property, treats runoff	Under $5,000	Limited volume disposed of, so many are needed, maintenance
Gray	Pervious paving	Parking lots, patios, driveways, anything except paved roads due to traffic loading	Reduces roadway and parking lot flooding	$10-20/sf, requires bumpers and sub-base to maintain paver integrity	Must be maintained via vacuuming or the perviousness fades after 2-3 years
Green	Detention	Common for new development, but difficult to retrofit; limited to open areas	Removes water from streets, reduces flooding	$200K/ac	Land availability, maintenance of pond, discharge location Uses up land that could otherwise be developed
Gray	Exfiltration Trench	Any low-lying area where stormwater collects and the water table is more than 3 ft below the surface; densely developed areas where retention is not available, roadways	Excess water drains to aquifer, some treatment provided	$250/ft	Significant damage to roadways for installation, maintenance needed, clogging issues reduce benefits
Gray	Central sewer installation	All areas where there are septic tanks. Mostly a water quality issue	Public health benefit of reducing discharges to lawns, canals, and groundwater from septic tanks	$15,000 per household	Cost, assessments against property owners, property rights issues

Strategy Class	Implementation Strategy	Applications	Benefits	Cost	Barriers to Implementation
Green	Flood prone property acquisition	Regional agency - could be any low-lying areas	Removes flood prone areas from risk	$2K-$100K/ac depending on whether it is already developed	Difficult to implement if occupied, issues with willing sellers, cost, lack of funds for acquisition
Gray	Pump stations	Any low-lying area where stormwater collects, and there is a place to pump the excess stormwater to such as a canal; common for developed areas	Removes water from streets, reduces flooding	Start at $1.5 to 5 million each, number unclear without more study	NPDES permits, maintenance cost, land acquisition, discharge quality
Gray	Armored sewer systems	Any area where gravity sanitary sewers are installed	Keeps stormwater out of sanitary sewer system and reduces potential for disease spread from sewage overflows	$500/manhole	Limited expense beyond capital cost
Gray	Sea walls	Barrier islands and downtown coastal areas	Protects property	$1200/ft	Private property rights, neighbors
Policy	Changes in land use	Applicable universally	Achieves flood risk mitigation by adjusting permitted land use	Low but may incur private property rights conflicts and litigation	Private property rights conflicts and litigation
Gray	Roadway base protection	Low-lying areas, coastal communities	Protects roads and access routes	$1 million per lane-mile	Cost, adjacent properties become uninsurable
Policy	Enhanced elevation of buildings	Developers would implement this for new construction	Reduced flood risk	Varies	Potential issues with building structure or latticework, and existing homes that are not elevated

2.5.3 Impacted Adjustment Areas

In the evaluation of flood risk management strategies within the framework of the National Flood Insurance Program Community Rating System (CRS), the concept of impact adjustment plays a pivotal role in determining the extent to which CRS-credited activities or elements influence the vulnerability of a community's Special Flood Hazard Area (SFHA) and the structures located within it. It's important to note that while the usual results of impact adjustment are related to the SFHA area, in this specific analysis, it was used 1-day 100-year storm event inundation area performed by FAU instead.

In this context, the following table presents a breakdown of the impact adjustment calculations for a 1-day 100-year storm event inundation. The values are expressed in acres and depict the areas of interest as well as the deductions considered in the evaluation process.

The outcomes of these calculations provide valuable insights into the impact adjustment scenarios:

With ALL State Lands:

This scenario reflects the remaining inundation area after accounting for deductions A, B, and C. It represents the effect of CRS-credited activities without considering the influence of state lands in managing flood risks.

With NO State Lands:

In this case, the remaining inundation area is determined by considering all deductions, including state lands (both open space and not open space– see **Error! Reference source not found.**).

These calculations highlight the dynamic nature of impact adjustment within the CRS framework. By accurately gauging the influence of individual elements, the system ensures that credit allocations align closely with a community's efforts in flood risk mitigation.

Table 11. Impacted Adjustment Areas for HUC 031402031101. Processed by FAU.

AREAS	**ACRES**
HUC-12 Sub-watershed: 031402031101	33266.17
All of the 1-day 100-year storm event inundation	**1652.17**
Subtract	
A. Bodies of Water in 1-day 100-year inundation > 10 acres	1106.58
B. Federal Land in 1-day 100-year inundation > 10 acres	0.00
C. Reservation/Tribal Land in 1-day 100-year inundation > 10 acres	0
D. State Land in 1-day 100-year inundation > 10 acres that is open space	130.52
E. State Land in 1-day 100-year inundation > 10 acres that is NOT open space	53.71
The remainder is either:	
With ALL State Lands: All of the 1-day 100-year inundation minus (A+B+C) or	545.59
With NO State Lands: All of the 1-day 100-year inundation minus (A+B+C+D+E)	361.36

2.5.4 Repetitive Loss Property Map

A Repetitive Loss (RL) property is a building that has had two or more loss or damage due to a specific hazard, such as floods, hurricanes, or other natural disasters, over $1,000 each, paid by the National Flood Insurance Program (NFIP) within any ten-year period since 1978. There are more than 122,000 RL properties in the nationwide (FEMA, 2005).

These data are essential for assessing the vulnerability of certain areas to recurrent losses and for developing strategies to mitigate the risks. However, due to privacy concerns, the data cannot be openly shared with the public. For this reason, the data were converted into a hot spot analysis map. These maps, instead of identifying the specific location of the repetitive loss properties, highlight clusters of repetitive loss claims and areas where the probability of repetitive losses is higher than would be expected by random chance. In other words, it helps pinpoint locations that have a higher concentration of properties prone to repetitive losses. **Error! Reference source not found.** indicates the results from hot spot analysis in point data, showing aggregated counts, and raster data, showing the estimated probability of repetitive loss.

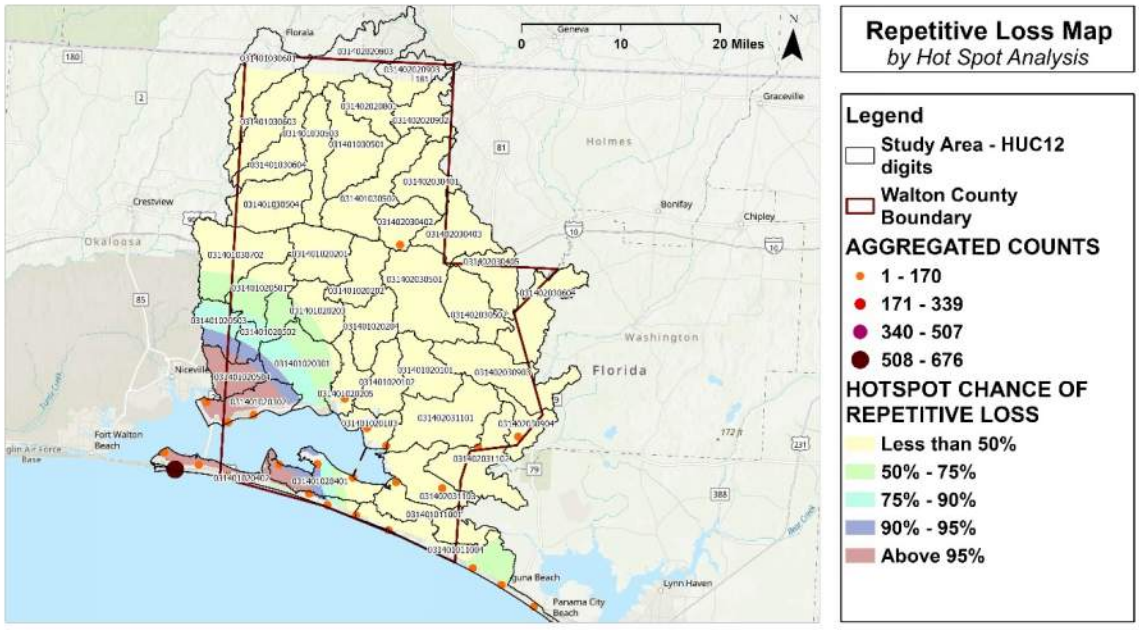

Figure 66. Repetitive Loss map for Walton County by Hot Spot Analysis. Processed by FAU. (Source Data: FEMA)

2.5.5 Priority Projects

While the basin does not have a significant amount of developed land, some parcels fall within the flood zone due to the area's susceptibility to a medium-to-significant flooding in both 1-day 100-

year storm events and 1-day 100-year + 5 feet sea level rise scenarios. In terms of land use priority, there are some parcels in tiers 2 (roads), 4, and 5 within the flooding zone. There are four parcels in Tier 1 of priority of land use, but fortunately, they are not in the flooding zone.

Examining the composite score, there are a total of 99 parcels within the flood zone that require attention. Among them, only one parcel is in the score range of 5-6, and it is a road (Rushing Cutoff), representing the highest priority for intervention. Additionally, there are 52 parcels with scores in the range of 3-4, which 41 are mobile homes, and 11 are roads, such as Co Highway 3280, Phillips Dr, Creekside Waterview Ct, Us Hwy 20, Creek View Ave, Black Creek Lodge Rd, E Edgewater Drive, and Mcdaniels Fishcamp Rd. Finally, there are 46 parcels with scores below 3, including 40 mobile homes and six orphanages or other non-profit organizations.

X.0 EXECUTIVE SUMMARY

The goal of the appendices to the watershed plan are to outline the issues associated with the individual HUC12s that contribute or impact the community's flood vulnerability and there for its flood protection efforts. Floodplain analysis includes developing a watershed model and identifying associated inundation polygons. It builds upon information generated from the watershed evaluation so that planning and management decisions can be formulated.

This appendix describes the issues and modeling associated with one of the HUC12s that affects Walton County. In developing the County-wide plan, this HUC 12 was analyzed so as to determine how it brings or removes floodwaters from the County. For the NFIP process the goal is to analyze all communities at the HUC12 level. From a community perspective the HUC12 is less useful to residents than a community-wide plan. Hence in all cases the HUC12 results were mosaicked into the community-wide plan. Details can be found in the HUC12 appendices, some of which were brought into the community plan.

To reduce redundancy, information of the plans, ordinances, policies and regulations were rolled up to the community-wide plan and will not be repeated in the appendices. Likewise, the community wide mapping was parced for HUC12 use.

1.0 WATERSHED CHARACTERIZATION

In this section, key aspects of the watershed are characterized. This is important for later being able to identify the most vulnerable areas and to mobilize resources to implement an action plan. Understanding the characteristics of the watershed involves gathering existing information and data sets from previous planning efforts. It is important to note that this step is iterative and ongoing as new data are generated and projects are implemented and monitored.

To assess the historical and current conditions of the study area, the following existing data sets that characterize the physical and natural features of the watershed were obtained for each HUC-12 sub-watershed in the study area:

- Topographic data (LiDAR)
- Relevant waterway locations
- Groundwater levels
- Soils data
- Land uses including vacant land, wetlands, impervious, etc.
- Precipitation records
- Catchment delineations for flood routing

In addition, the FEMA flood maps must be obtained, and the storm of interest must be identified for screening purposes (1-day, 2-year, 5-year, and 100-year events as well as the 3-day 25-year storm event to achieve class 4 in the CRS Manual). In developed areas, many sources of data are already available – the key is putting the key datasets in a format that can queried for screening to identify the priority areas of the watershed. Table 6 is a summary of datasets available at cwr3.fau.edu that were used to construct this plan.

This watershed master plan is a drilldown of the larger Walton County TMDL region, which involves 42 HUC 12-digit sub-watersheds (**Error! Reference source not found.**). **Error! Reference source not found.** shows Walton County Drainage Network and the location of urban areas (cities and towns). In **Error! Reference source not found.**, the HUC-12 (031402031102) is highlighted among all the HUCs to help identifying its location. (Figure 3).

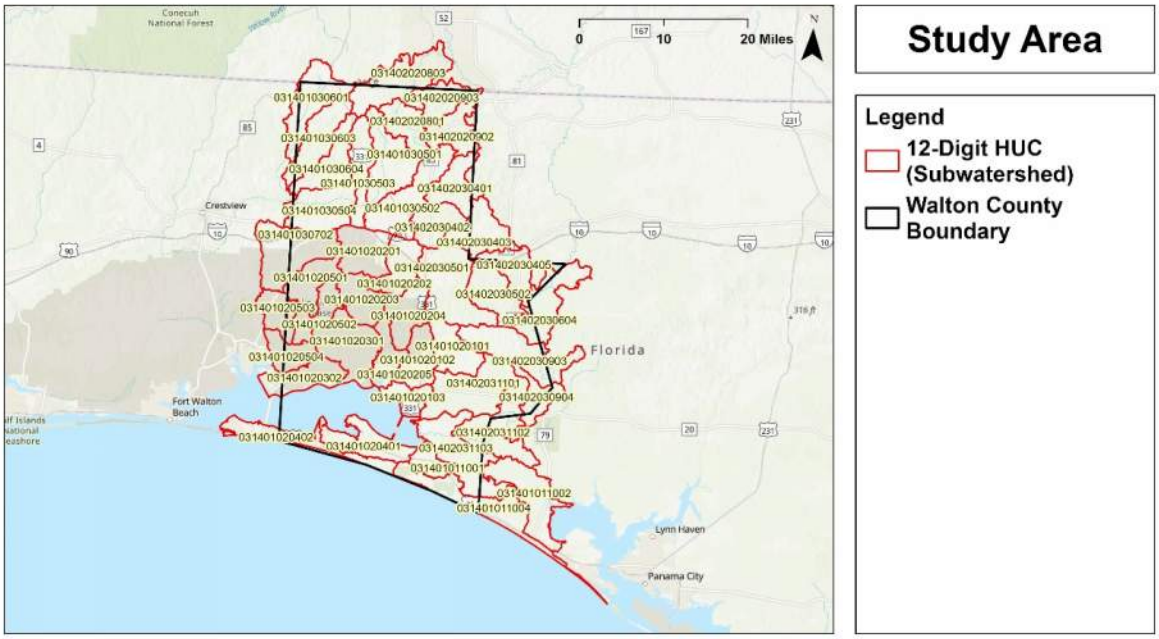

Figure 1. Walton County and all HUCs 12-digit sub-watershed, processed by FAU.

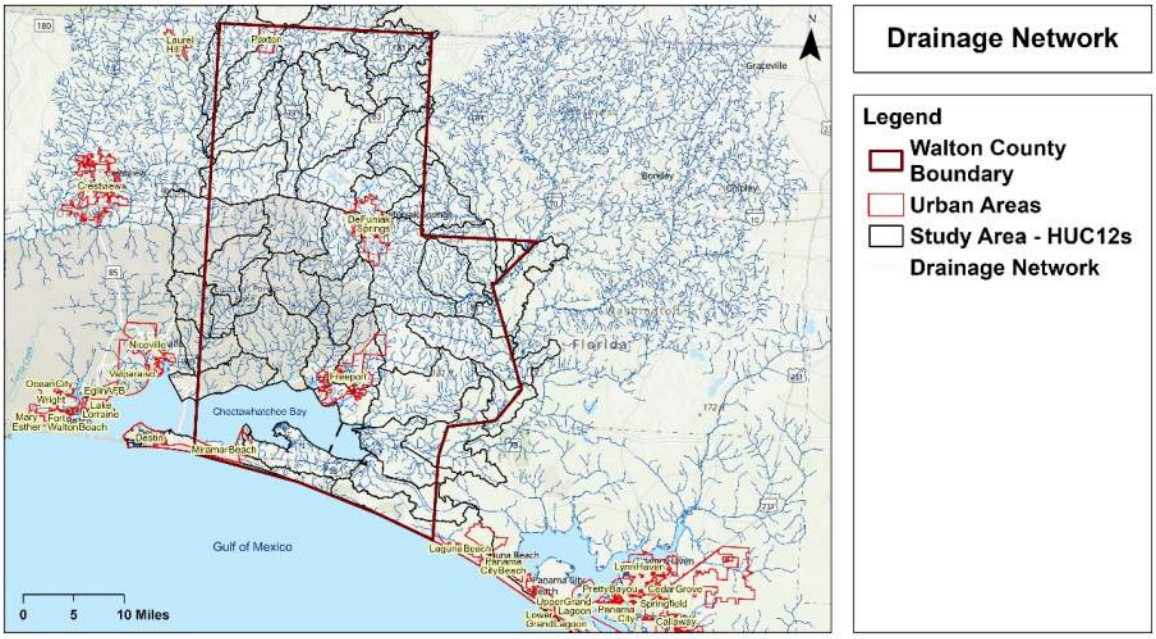

Figure 2. Walton County Drainage Network and urban areas (cities and towns), processed by FAU.

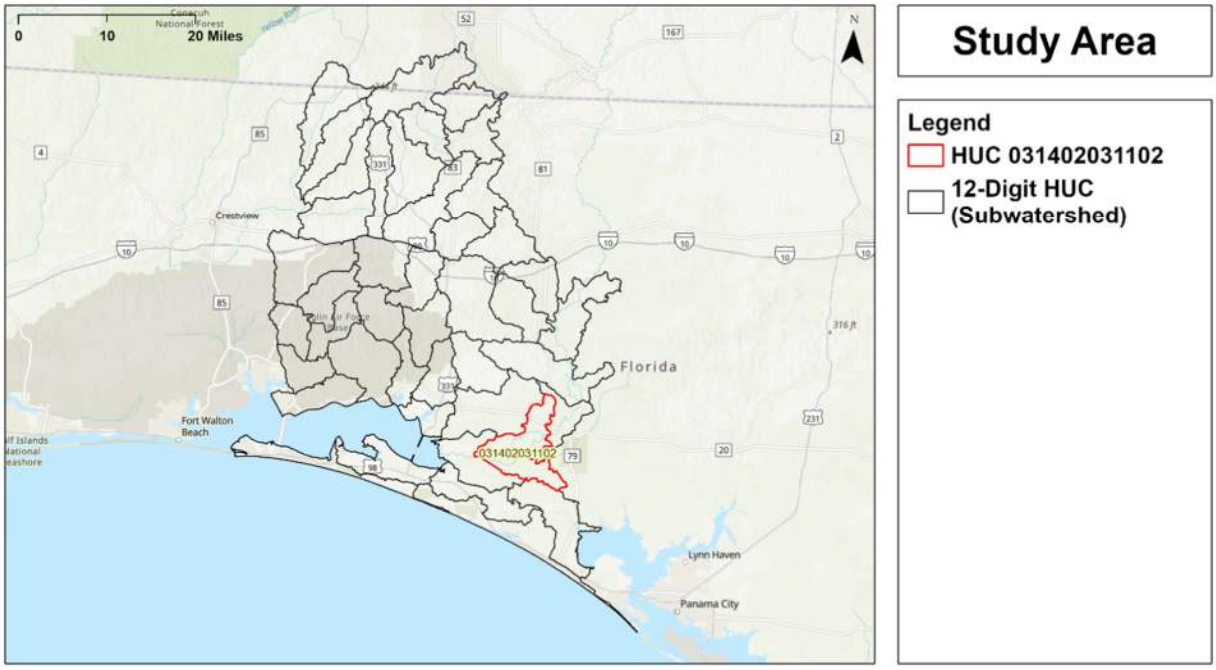

Figure 3. HUC 031402031102 sub-watershed location.

Located in the northwestern region of Florida, Walton County has 1,037.7 square miles of land and it is the 12th largest county in Florida by area, while also sits the highest point in the state,

with a height of 345 feet in its northern end. With a population of 75,305 residents according to the 2020 census and an estimate population in July of 2022 of 83,304, the county has experienced consistent growth within the past several years, driven by factors such as tourism, retirement migration, and regional population dynamics. The county was the residence for 55,043 people according to Census 2010, which leads to a percent change of 36.8% in 10 years, between 2010 and 2020, and a percentage change of 10.6% in two years, between 2020 and 2022 (United States Census Bureau).

The surge in population, particularly in the southern part of Walton County, has resulted in a corresponding expansion of infrastructure to cater to the growing needs. Essential facilities such as potable water systems, wastewater treatment plants, electrical utilities, roads, and schools have been developed to support this increasing population. However, the infrastructure expansion has brought about a significant change in the natural environment. Prior to the existing development, tropical cyclone impacts would be mitigated by natural barriers such as vegetated sand dunes, wetlands, and deserted beaches, which would absorb some of the destructive forces. Now, with the proliferation of costly infrastructure and residential dwellings in coastal areas, these storms pose a higher risk of potential damage. The very areas where development is occurring are becoming more vulnerable to the impact of severe storms, highlighting the importance of considering and implementing adequate measures to address potential storm damage in these coastal regions (Walton County Local Mitigation Strategy Plan, 2015).

Demographically, Walton County presents a heterogeneous age distribution, encompassing a blend of younger and elderly cohorts. The median age of approximately 44 years reflects the presence of both younger families and retirees seeking a serene and picturesque environment. Ethnically, the county' population is predominantly White with smaller yet notable populations of Hispanic/Latino, African American, and other racial/ ethnic groups.

Economically, the tourism sector stands as a dominant force in Walton County, constituting 23.4 percent of the workforce, according to Walton County Economic Development Alliance in 2011, due to its renowned beach destinations, such as Santa Rosa Beach, Miramar Beach, and the New Urbanist Communities of Seaside and Rosemary Beach. Following closely behind is the trade, transportation & utilities sector, accounting for 20.3 percent of employment, while construction stands at 10.0 percent in third place. Education, health care services, and public administration also play significant roles within the top five employment sectors, reflecting the diversified economic landscape of the county (Walton County Local Mitigation Strategy Plan, 2015).

The natural environment in Walton County contributes to its distinctive appeal to visitors and tourists. The county's coastal environment along the Gulf of Mexico showcases picturesque vistas, including white sand beaches, undulating dunes, and coastal dune lakes. These lakes, a rarity worldwide, provide unique ecological habitats. Walton County is also committed to environmental conservation, with designated protected areas comprising state parks, forests, and wildlife

management zones. These preserved landscapes offer abundant opportunities for recreational activities, including hiking, fishing, and birdwatching.

The presence of wetlands and waterways further enhances the natural attributes of Walton County. Various rivers and creeks alongside Choctawhatchee Bay permeate the landscape, fostering diverse ecosystems and serving as crucial habitats for a wide range of wildlife species. This rich natural heritage encourages exploration and nurtures an appreciation for the environment.

DeFuniak Springs serves as the county seat and boasts a diverse economy. Anchored by sectors such as healthcare, education, retail, government services, and a thriving small business community, DeFuniak Springs offers a range of employment opportunities. Surrounded by the natural beauty of forests, lakes, and wetlands, the city enjoys the presence of Lake DeFuniak, a noteworthy natural resource. With a population of approximately 5,100 residents, DeFuniak Springs is a vibrant city featuring a mix of economic activities. The land area of DeFuniak Springs is approximately 12.6 square miles (32.7 square kilometers).

Freeport boasts a diverse demographic profile, and a developing economy. The city is situated along the shores of Choctawhatchee Bay, which provides opportunities for recreational opportunities and supports local ecosystems. Surrounded by lush forests and intersected by waterways, Freeport enjoys a rich environmental setting. In terms of economics, Freeport's economy is in a phase of growth and diversification, with sectors including healthcare, education, retail, and small businesses. The city is also strategically positioned for future economic expansion due to its proximity to major transportation corridors. Demographically, Freeport is a close-knit community with a population of approximately 2,600 residents, comprising a mix of permanent residents, retirees, and individuals seeking a suburban or rural lifestyle. The city reflects a diverse demographic composition, showcasing a variety of cultures, and backgrounds. Freeport occupies a land area of about 13.6 square miles (35.3 square kilometers)

Further along the coast, Miramar Beach stands as a coastal gem known for its tourism and hospitality industry. Luxury resorts, vacation rentals, gourmet restaurants, high-end retail shops, and entertainment venues thrive within this bustling city. Miramar Beach's main attraction lies in its stunning white sand beaches along the Gulf of Mexico, providing endless opportunities for beach activities and water sports. Its boundaries extend into neighboring Okaloosa County, attracting a blend of permanent residents, vacation homeowners, and rental property occupants. Miramar Beach, including its neighboring areas, covers an estimated land area of around 4.7 square miles (12.2 square kilometers).

Continuing along the Gulf Coast, we encounter Santa Rosa Beach. This coastal community is renowned for its vibrant tourism industry, offering a plethora of accommodations ranging from upscale resorts to charming vacation rentals. Its demography reflects a mix of permanent residents, seasonal visitors, and individuals seeking a coastal lifestyle, resulting in a diverse and dynamic community. Santa Rosa Beach spans a larger area compared to other cities in Walton County, with an estimated land area of approximately 31.2 square miles (80.8 square kilometers).

A summary of the existing CRS classifications for the communities in the study area is listed in **Error! Reference source not found.**. No cities in Walton County are listed in the FEMA Community Rating System Eligible Communities.

Table 1. Community Rating System for Walton County. Effective April 1, 2023.

Community #	**Community Name**	**CRS Class Rating**	**Premium Discount for SFHA**	**% Discount for Non- SFHA**	**Status**
120317	Walton County	6	20%	10	Cycle

(Source Data: FEMA)

Figures 12 and 13 is the county-wide report show the current and projected land use for the County. Based on the 2017 future land use for Walton County, only 7.07% of the land use in the county is urban and built up, and water/wetlands makes up 29.16% of the land use. The majority of land is upland forest, with 48.3%, as shown in **Error! Reference source not found.**.

Table 2. Land Use in Walton County (Prepared by FAU from future land use map) versus land use in the entire watershed

Level 1 Land Use-Land Cover Type	**Area (Acres)**	**Percentage of Total**
Agriculture	52958.94669	7.17%

(Source Data: (NWFWMD 2017)

Walton County has a history of flooding and has implemented various measures for flooding mitigation over the years (see section 1.12 for more details). The County has experienced flooding primarily due to heavy rainfall events and proximity to large water bodies such as the Gulf of Mexico, Choctawhatchee Bay, and numerous rivers and creeks. The topography of the region, with low-lying areas in the coastal areas and wetlands, also contributes to flood vulnerability. The proximity to the ocean (Gulf of Mexico) makes the county vulnerable to sea level rise. Over the years, Walton County has faced multiple flooding incidents, including:

- March 1997: Heavy rainfall led to significant flooding throughout the county, resulting in property damage and road closures.
- April 2009: Intense storms caused widespread flooding, damaging homes and infrastructure and resulting in the declaration of a state of emergency.
- April 2014: Heavy rainfall caused severe flooding, leading to the evacuation of some residents and the closure of roads.

Today, the goal of a stormwater management system in many communities is to keep the community as a place to live and do business while limiting risk from damage due to flooding. The short-term impacts from stormwater include flooding in low-lying areas and standing water in areas with limited soil storage capacity. Less common, but of increasing frequency, is the potential for extensive inundation of some areas, especially low-lying areas, during periods with high groundwater levels and groundwater impacted by sea level rise. As a result, there is a need to understand the economic impact of flooding events and to create cost-effective stormwater infrastructure and policy solutions to protect property. This means preserving as much property and economic activity as possible without disrupting current activity or expending funds on inappropriate projects with limited long-term or social value.

1.1 Surface Topography

Topography is a key parameter that influences many of the processes involved in flood risk assessment, and thus, up-to-date, high-resolution, high-accuracy elevation data are required. In order to meet the requirements for FEMA Risk Mapping, Assessment, and Planning (RiskMAP), 1-meter (2015 to present) and 1/9 arc-second (~ 3-meter) (2010 -2015) LiDAR DEMs were acquired. The 1 m × 1 m LiDAR tiles were kriged to create a topographic map of the study area (**Error! Reference source not found.**). This accuracy meets the 3DEP Quality Level 2 vertical root mean square error accuracy threshold of ±10 cm for FEMA (Arundel et al., 2015). The LiDAR used for this basin was 2016.

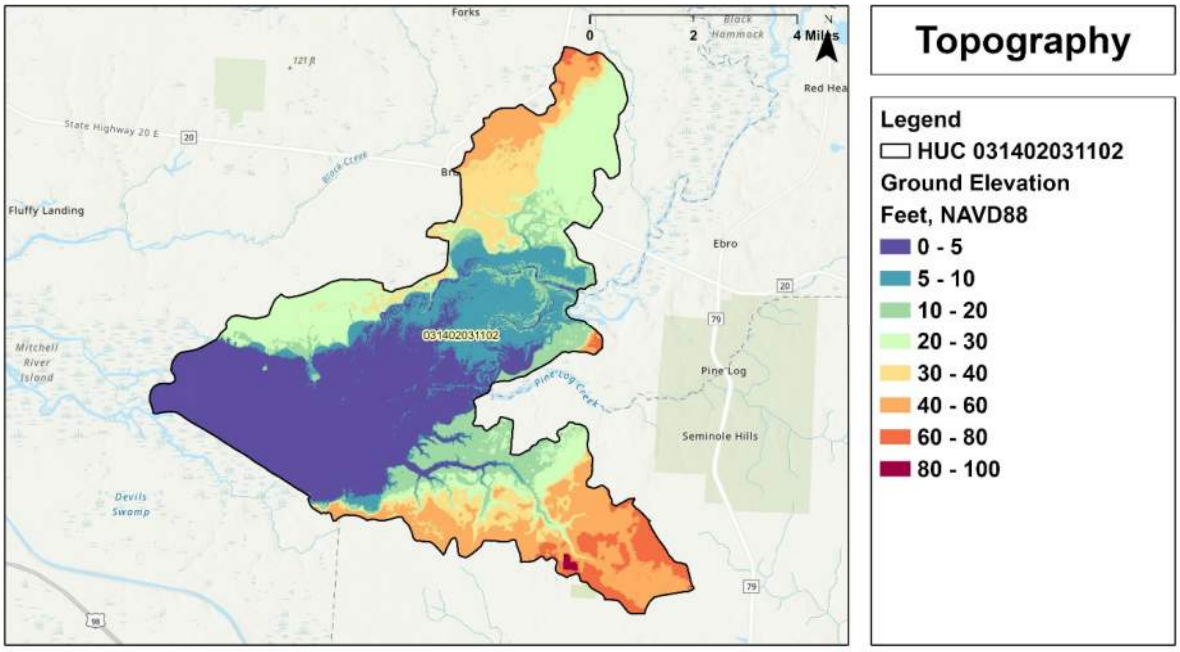

Figure 4. Topographic map of the HUC 031402031102 sub-watershed, processed by FAU. (Data Source: USGS)

1.1.1 Geomorphological Considerations

Walton County's coastal area is characterized by the presence of barrier islands, extensive sandy beaches, and coastal dune systems. These features are influenced by the dynamic processes of wave action, tidal currents, and wind-driven sediment transport. The shoreline is subject to natural changes, including erosion and accretion, which significantly shape the coastal geomorphology. Inland Walton County exhibits a mix of wetlands, forests, rolling hills, and rivers. These landforms are influenced by a combination of factors, including underlying geology, fluvial processes, and the region's hydrological regime.

Like many areas in Florida, Walton County is underlain by limestone formations. The specific composition and properties of these limestone formations in Walton County may vary. However, limestone is generally known for its porous nature, which allows for the absorption and storage of water. Underground aquifers within the limestone formations can hold significant volumes of freshwater, contributing to the region's water resources.

For context, the FIRM panel index of HUC 031402031102 sub-watershed is shown in **Error! Reference source not found.**.

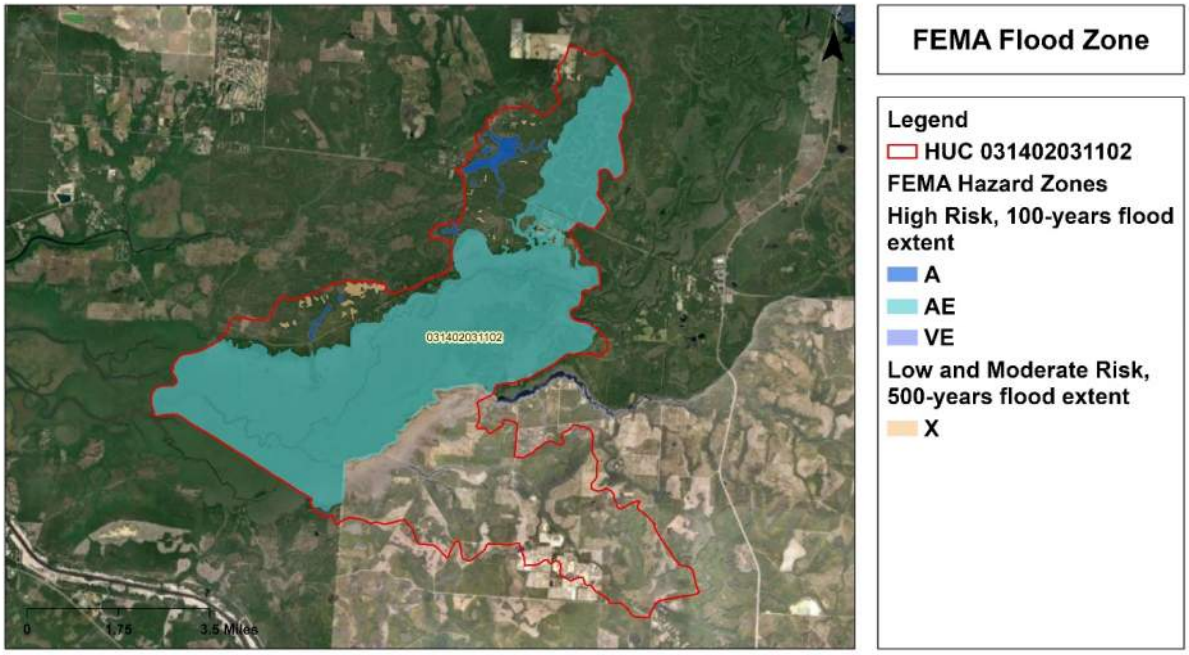

Figure 5. FEMA Flood Zone map (2020) for HUC 031402031102 sub-watershed, processed by FAU.
(Data Source: FEMA)

1.1.2 Waterway Features

In Walton County, Florida, the waterway features are primarily influenced by the presence of rivers, creeks, bayous, and the proximity to the Gulf of Mexico. To the south of Walton County lies the Gulf of Mexico. Sandy beaches, barrier islands, and the open waters of the Gulf itself characterize the coastline along the Gulf. The Gulf of Mexico influences the coastal processes, including wave action, tidal currents, and sediment transport along the shoreline. The combination between sea level rise and King tide would have detrimental consequences for the county costal area, including the sub-watershed 031402031102 as it will reach the area thought Choctawhatchee Bay.

Walton County is home to several rivers and creeks that meander through its landscape. These waterways provide drainage for the inland areas and contribute to the overall hydrological system. Examples of significant rivers in the county include the Choctawhatchee River and the Shoal River. In addition, Walton County features bayous and estuaries that connect inland water systems to the Gulf of Mexico.

Choctawhatchee Bay serves as a vital estuarine ecosystem, where freshwater from rivers and creeks mixes with the saltwater from the Gulf of Mexico, serving as a vital estuarine ecosystem.

This unique brackish water environment supports a rich diversity of flora and fauna, including various fish species, shellfish, migratory birds, and wetland vegetation, contributing to the overall biodiversity of the region. It also plays a significant role in the local economy of Walton County as it supports commercial and recreational fishing industries, providing livelihoods for local fishermen and contributing to the seafood industry, while also offering a range of recreational opportunities for residents and visitors alike, such as boating, kayaking, paddle boarding, and sailing. **Error! Reference source not found.** shows the bathymetry offshore.

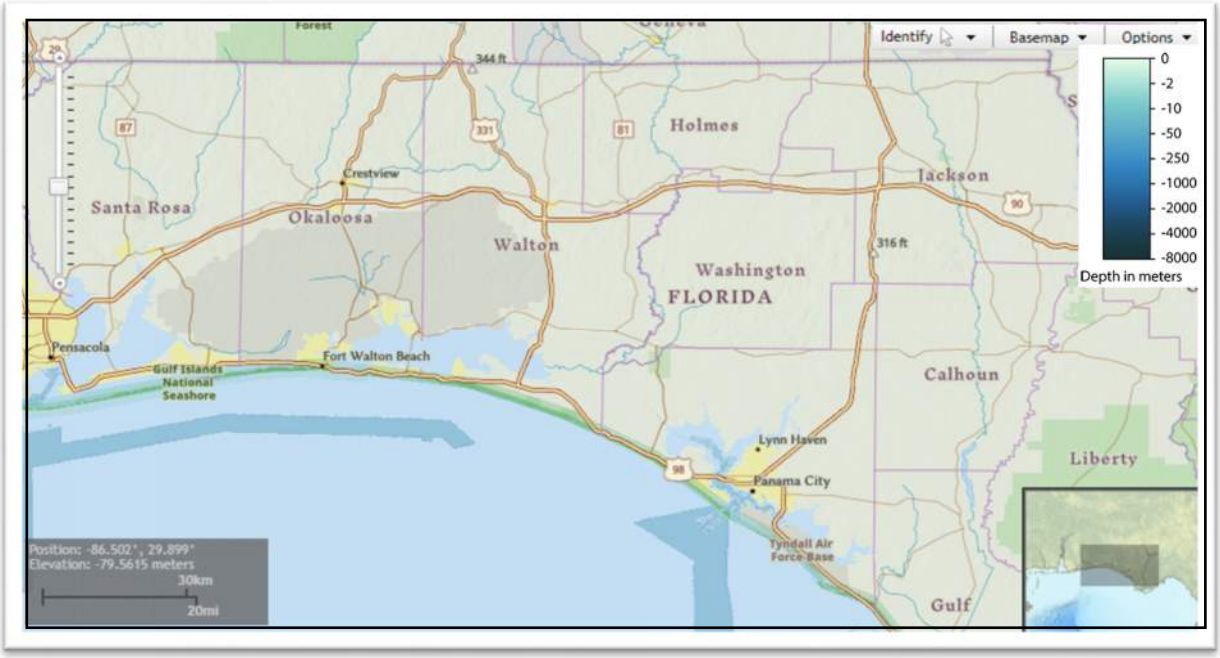

Figure 6. Bathymetry map of the shore of Walton County and surrounding counties of Florida Panhandle.
(Source: ncei.noaa.gov/maps/bathymetry/)

Numerous tributaries exist throughout both the freshwater and estuarine portions of the watershed and can influence the overall hydrology of the area depending on rainfall and regional hydrological conditions. **Error! Reference source not found.** shows the location of all four surface water stations along with ground water stations (wells) and the drainage network of Walton County.

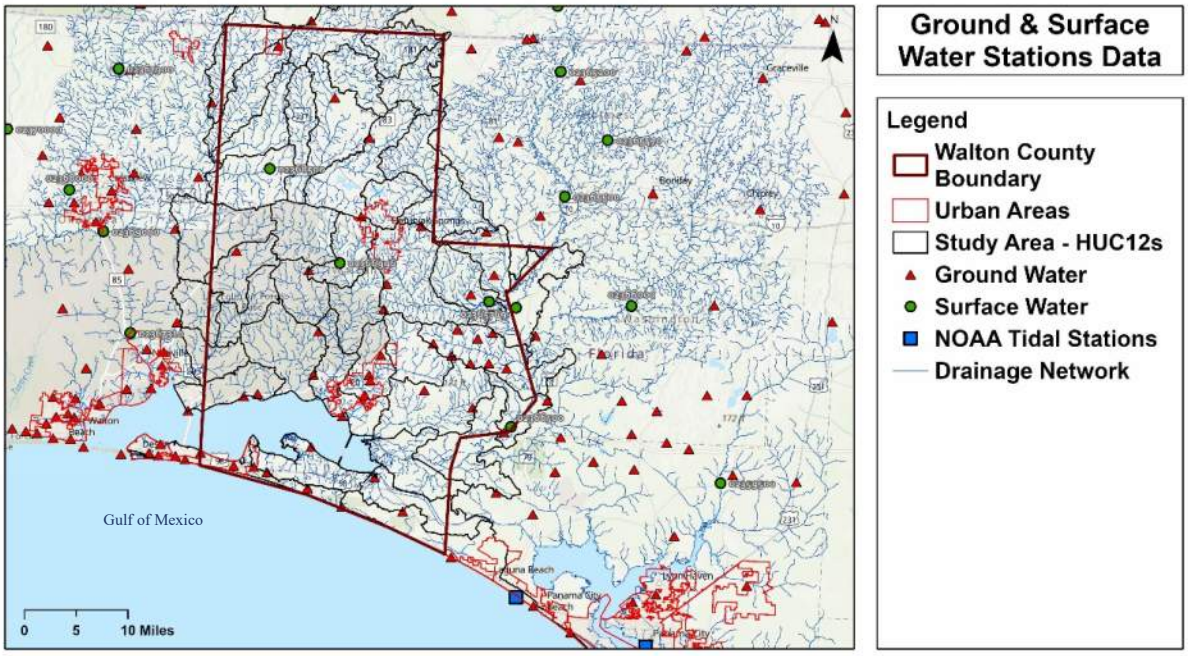

Figure 7. Ground & Surface Water Stations with drainage network for Walton County, processed by FAU.
(Data Source: USEPA – National Hydrographic Dataset (NHD) and NOAA's Tides)

1.1.3 Hydrologic Boundaries

The geographic area of the subject sub-watershed should be clearly defined to ensure that implementing the WMP will address all the major sources and causes of impairments and threats. Although there is no rigorous definition or delineation of this concept, one way to identify the geographic extent of the watershed master planning effort is to consult the United States Geological Survey (USGS) map of hydrologic units. A hydrologic unit is part of a watershed mapping classification system showing various areas of land that contribute surface water runoff to designated outlet points, such as lakes or stream segments. USGS designates drainage areas as sub-watersheds (including smaller drainages) numbered with 12-digit hydrologic unit codes (HUCs), nested within watersheds (10-digit HUCs). These are combined into larger drainage areas called subbasins (8 digits), basins (6 digits), and subregions (4 digits), which make up the large regional drainage basins (2 digits).

Region>>Subregion>>Basin>>Sub-basin>>Watershed>>Sub-watershed

The major water bodies in the HUC 031402031102 sub-watershed include:

- Choctawhatchee River

- East River
- Otter Creek
- Sewell Branch
- Boutwell Branch
- Dismal Creek

Given that stream flow data are critical for estimating flooding, **Error! Reference source not found.** shows the historical streamflow during June 2022 to July 2023 for USGS 02366500. However, as there are only four surface water station within Walton County, it was necessary to use the nearest station to the sub-watershed 031402031102, which is USGS 02366500 Choctawhatchee River NR Bruce FLA.

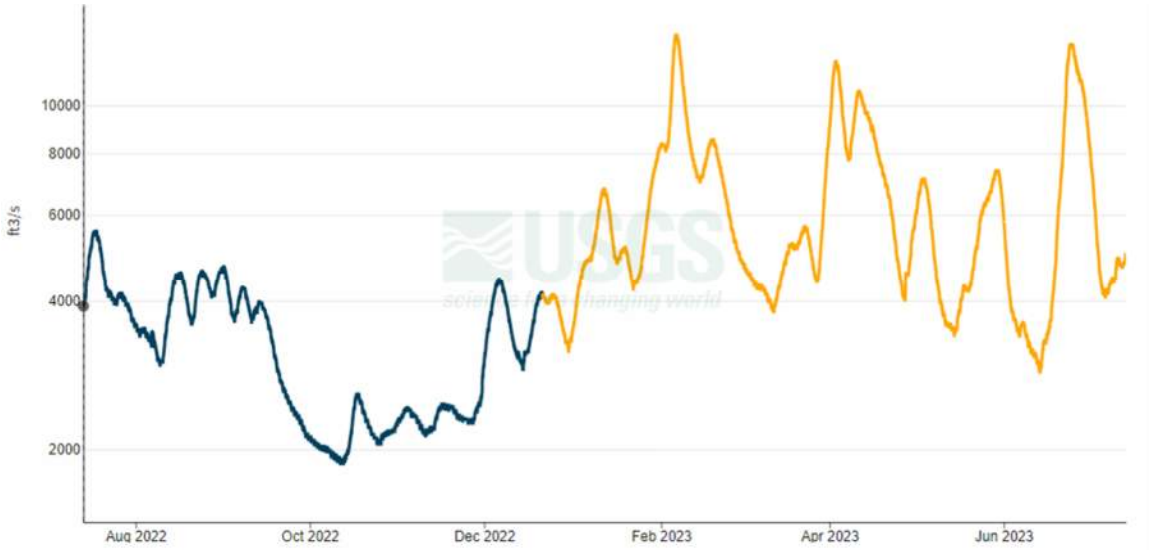

Figure 8. Average streamflow for Choctawhatchee River NR Bruce FLA (USGS 02366500 Surface-Water, June 2022 to July 2023).
(Source: USGS Water Data Services, available at https://waterdata.usgs.gov/monitoring-location/02366500/#parameterCode=00065&period=P365D)

1.2 Groundwater

In this region of Florida, there is a direct interaction between groundwater and surface water. In addition to low land elevations and topographic relief, the groundwater and surface water are controlled by the canals, rivers, and tides. Since there is a limited number of groundwater monitoring stations, the strong relationship between groundwater and surface water was leveraged to develop a 99th- percentile surface of the water table elevation for mapping purposes. To establish a common date for modeling, the recorded groundwater table elevations were sorted in ascending

order to determine the 98th - 100th percentile date of occurrence in Excel®, following the procedure detailed in Romah (2011). This procedure was automated for this effort using a python code to process the groundwater data more efficiently. Outliers and anomalous groundwater levels in the database are initially identified (e.g. catastrophic storm events) and replaced by region-specific mean values based on observations available from the nearest well. Missing date-specific data are estimated using simple temporal interpolation based on observations available in time. If a station (or monitoring well) data contains large amounts of missing data, it is not used in the generation of the groundwater surface.

In Walton County, the average annual rainfall is abundant, reaching 65 inches at DeFuniak Springs. This rainfall predominantly infiltrates the sand-and-gravel aquifer and eventually seeps into streams or the underlying artesian Floridan aquifer. The county's two major aquifers are the sand-and-gravel aquifer and the Floridan aquifer. While the sand-and-gravel aquifer provides water for rural domestic use and plays a crucial role in water storage and streamflow maintenance, it also serves as a recharge source for the Floridan aquifer. Water from the sand-and-gravel aquifer contains varying levels of dissolved solids, pH, and iron content. The Floridan aquifer, being the primary water supply source, underlies the entire county and yields around 500 to 1,000 gallons per minute from wells, except along the Gulf Coast where the permeability is lower. Recharged by leakage from the sand-and-gravel aquifer, the Floridan aquifer's movement is predominantly southward away from the potentiometric high in northwestern Walton County. It discharges through springs, seeps along the Choctawhatchee River, and by wells. In southern Alabama, the Floridan aquifer is directly recharged by rainfall when it is exposed or close to the land surface. (Bureau of Ecology, 1974).

Once a common time period is determined across the majority of shallow groundwater wells, canal data can be gathered for that common date (and two days prior, in the event the canals were deliberately lowered). for that common date (and two days prior, in the event the canals were deliberately lowered). Data was obtained from the NWFWMD and processed by FAU at cwr3.fau.edu. Between stations, an ArcGIS tool permits a line to be drawn to replicate the canals and establish points in a gradient between stations. The same is true for the ocean, but it is a constant head boundary. The canals form boundary conditions for the screening tool on the edges of the basin and affect localized groundwater. The tide issue is resolved by using the common date for high tide.

Error! Reference source not found. shows the drainage network of HUC 031402031102 and points out the location of the ground water stations in the surroundings. A groundwater-surface layer for the HUC 031402031102 sub-watershed was created using several datasets including water level data from USGS and NWFWMD and groundwater elevation contour maps. The datasets were used to generate a raster surface of the groundwater elevation (**Error! Reference source not found.**).

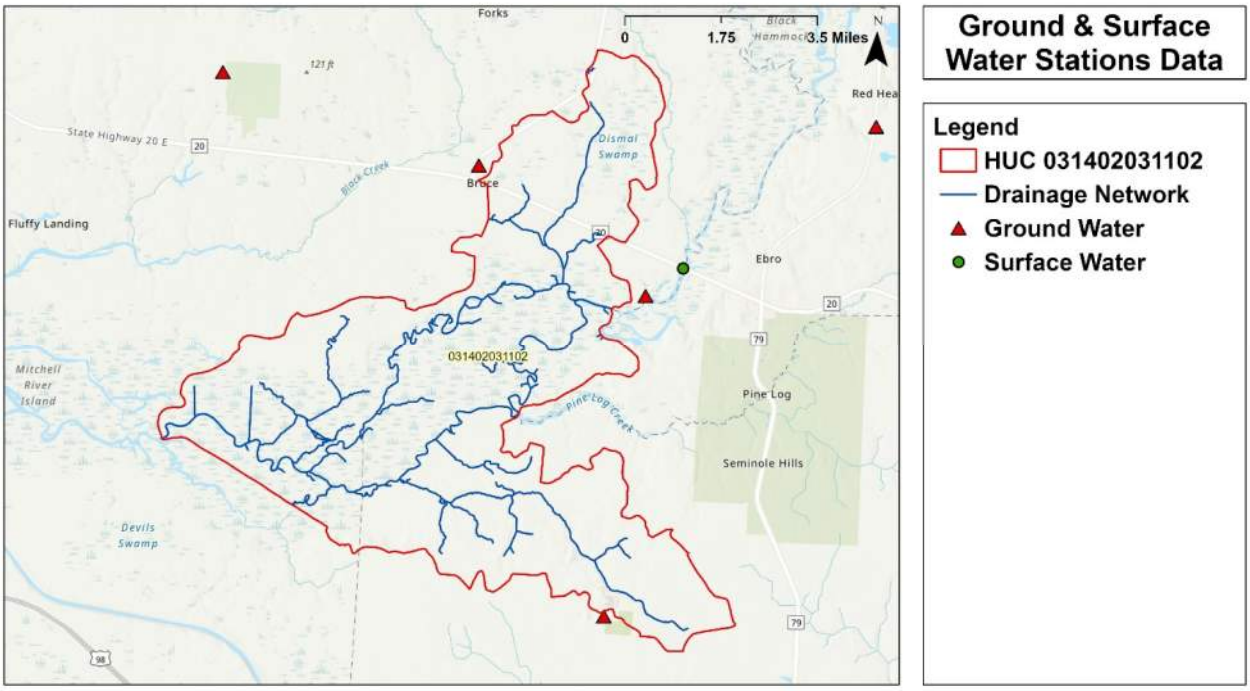

Figure 9. Ground and Surface Water Stations in the HUC 031402031102 sub-watershed, processed by FAU.
(Data Source: USEPA – National Hydrographic Dataset (NHD)

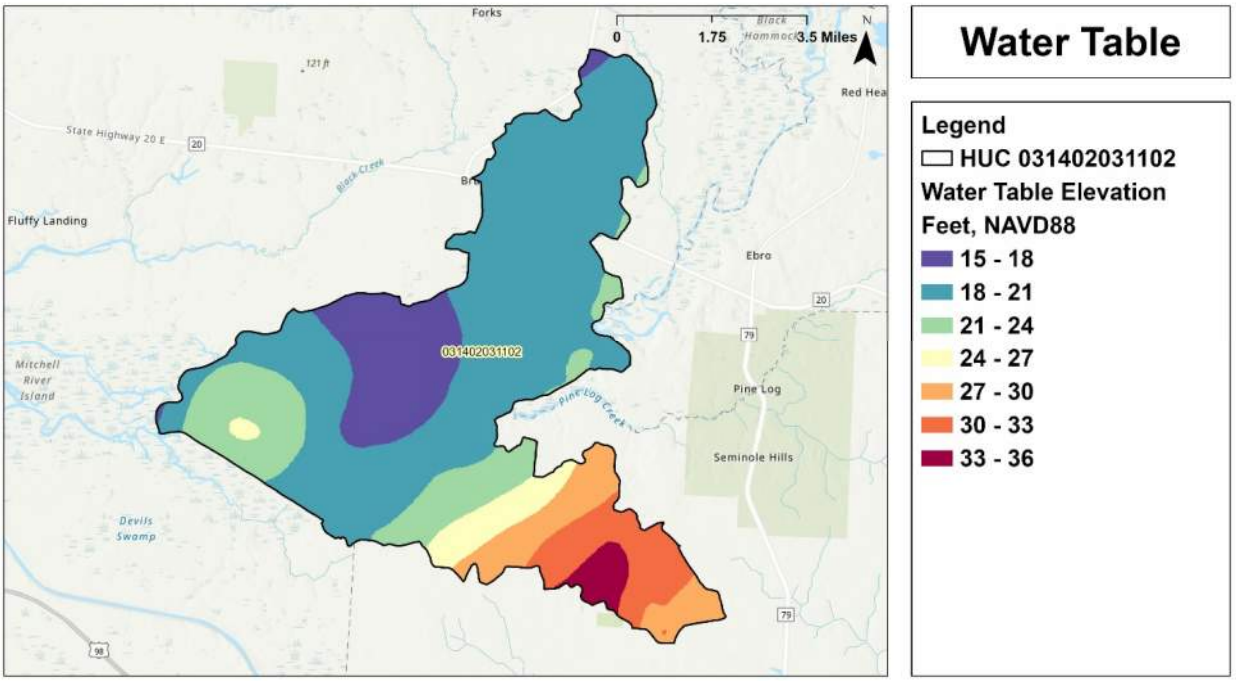

Figure 10. Elevation of the top of the surface groundwater layer for the HUC 031402031102 sub-watershed, created by multiple linear regression analysis – elevation NAVD88, processed by FAU.
(Data Source: USGS and NWFWMD)

1.3 Surface Water/Tides

Historically, surface water and tides have been an important factor in determining how much freshwater is delivered, how fast this water enters wetlands and estuaries, and the quality of that water. Evapotranspiration and rainfall do not coincide in the study area, which makes water supply planning difficult. **Error! Reference source not found.** shows the average precipitation over Walton County for every month of the year between 2011 and 2023 - each rectangle is a month and each column is a year. The 12-month total precipitation decreased 7.5 inches from May 1900 to April 2023. From May 1900 to April 2023, the average 12-month total precipitation was 60.5 inches for the entire county.

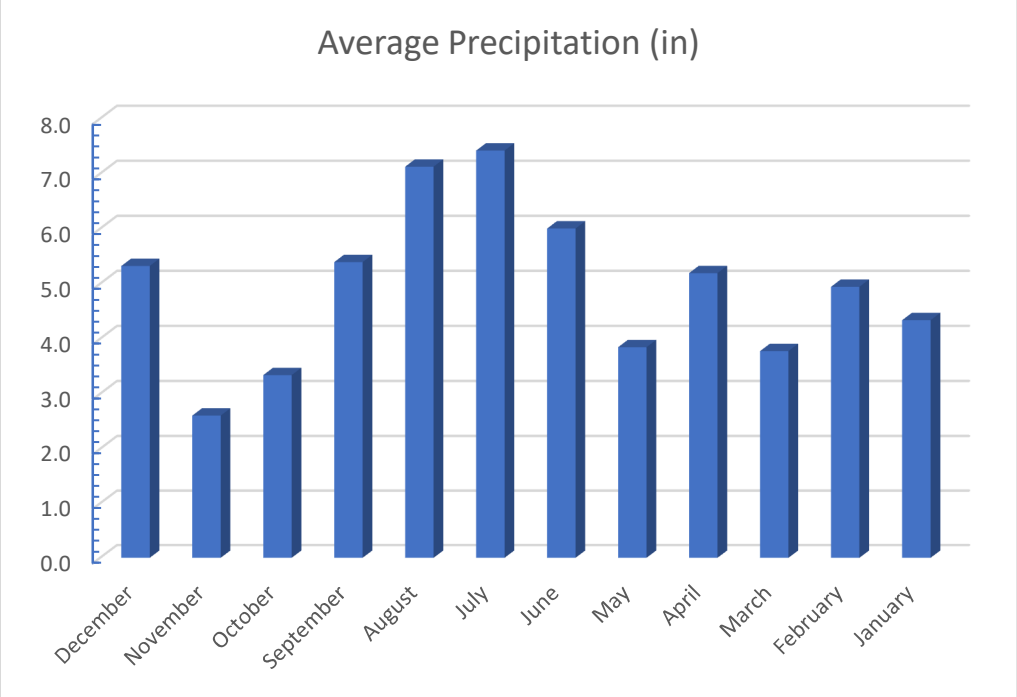

Figure 11. Monthly precipitation in Walton County, FL (2011-2023).
(Data Source: Florida Weather Data, available at https://data.usatoday.com/weather-data/walton-county/12131/1975-04-01/table/)

While the topography (Section 1.1) and native soil (Section 1.4) create an environment that is highly permeable and capable of infiltrating significant percolation into the soil, changes in land use and land cover have resulted in water falling on impervious areas, where the water collects in pools or runs off rapidly, in direct contrast to the natural condition. This runoff flowing over impermeable regions can lead to larger scale flooding.

Tidal data can be gathered from NOAA tidal gages and other gages monitored by local governments. The location of tide gages is important to ensure they accurately depict tides, as opposed to inland waters. To set a boundary for the coastal areas, the high tide on the common date from 12/03/2018 to 12/10/2018 was selected. **Error! Reference source not found.** shows the two closest tide stations to Walton County. Since there is none NOAA tide station in Walton County, the Panama City Beach station (8729210) was used.

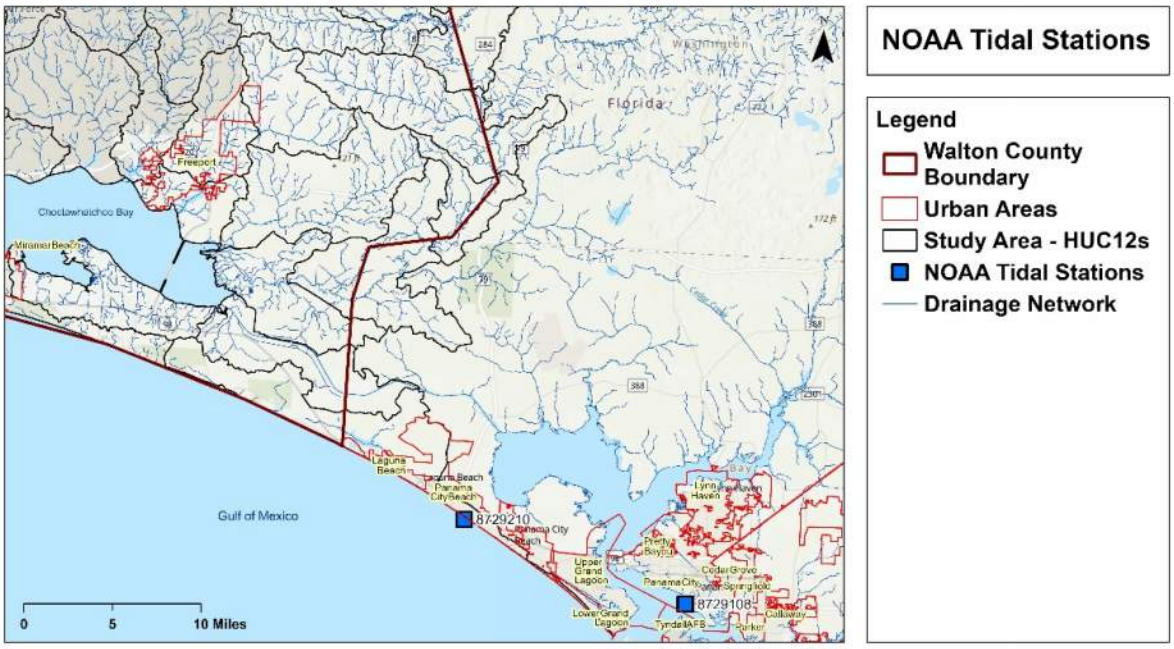

Figure 12. Locations of Florida tidal stations maintained by NOAA near to Walton County, processed by FAU.
(Data Source: USEPA – National Hydrographic Dataset (NHD) and NOAA's Tides)

1.4 Soils

Soil can store water if there is adequate distance between the topographic surface and the groundwater, and the soil types are capable of absorbing the water. Soil storage capacity is the volume of soil pores in the unsaturated zone that is available to store infiltrated stormwater (Gregory et al., 1998). Throughout Florida, it is common to have large volume storm events that fill the voids in the unsaturated zone as shown in Figure 13.

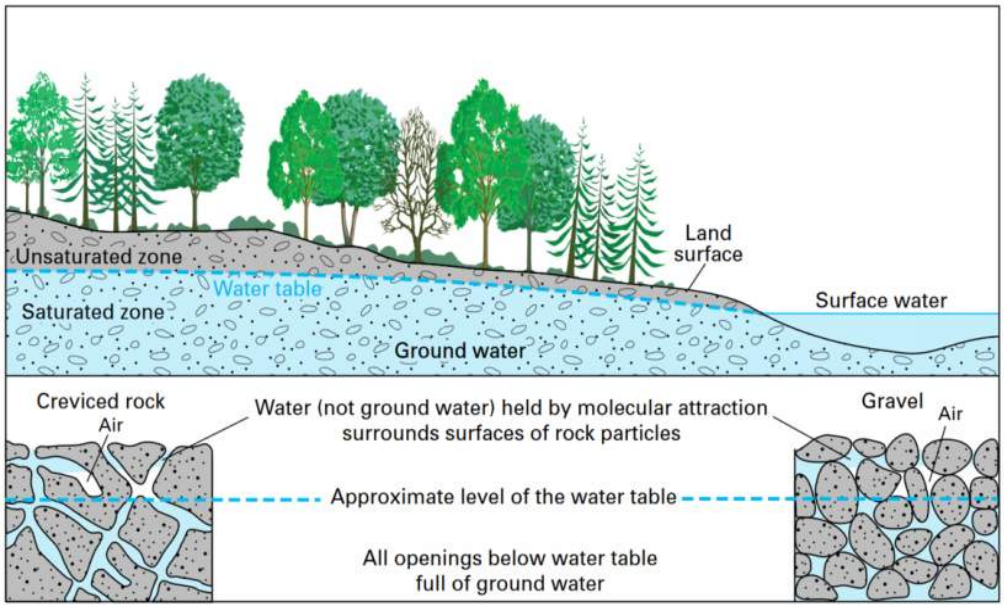

Figure 13. Zones where underground water exists.
(Source: USGS, 2020)

The unsaturated zone is the portion of the subsurface above the water table that contains soil/rock and air and water in its pores as shown in Figure 14. This zone affects the rate at which the aquifer is recharged by controlling water movement from the surface of the land downward towards the aquifer. During rain events, the soil voids fill up quickly resulting in the water table rising to the surface, and the surplus rainfall becomes runoff.

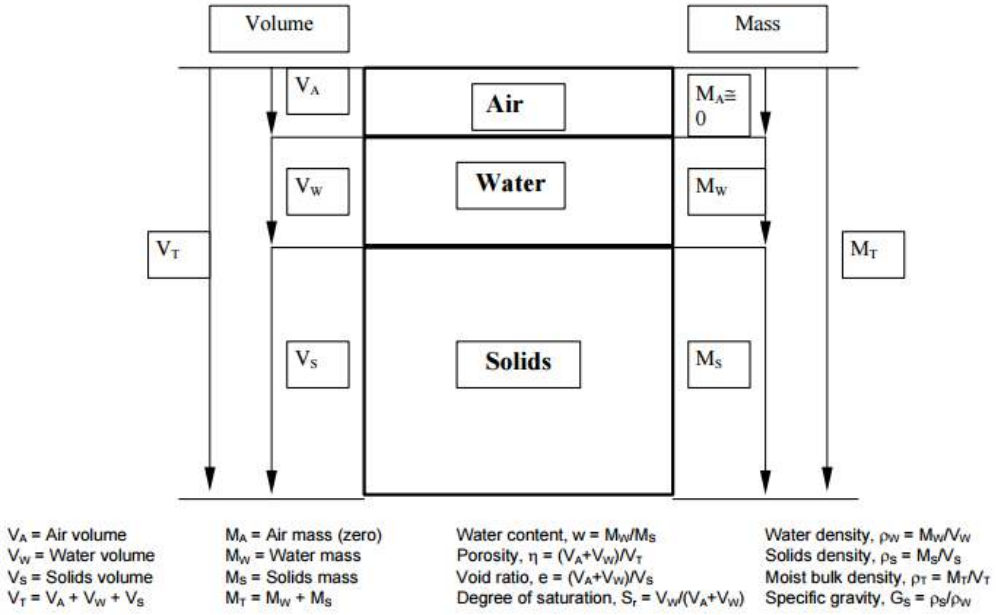

Figure 14. Saturated zone soil phase diagram and definitions.
(Source: Gregory et al., 1998)

Soil data is available from the United States Department of Agriculture (USDA) or other agencies in the form of maps that can be incorporated as a GIS layer. The Gridded SSURGO (gSSURGO) dataset from USDA is chosen. This dataset is similar to the standard product from USDA Natural Resources Conservation Service (NRCS) Soil Survey Geographic (SSURGO) database, but is in the Environmental Systems Research Institute, Inc. (ESRI®) file geodatabase format. A file geodatabase allows for statewide or even Conterminous United States (CONUS) tiling of data. The gSSURGO dataset contains all of the original soil attribute tables in SSURGO. All spatial data are stored within the geodatabase instead of externally as separate shape files. Both SSURGO and gSSURGO are considered products of the National Cooperative Soil Survey (NCSS). **Error! Reference source not found.** shows the unsaturated zone found by the difference between the groundwater elevation layer and surface topography.

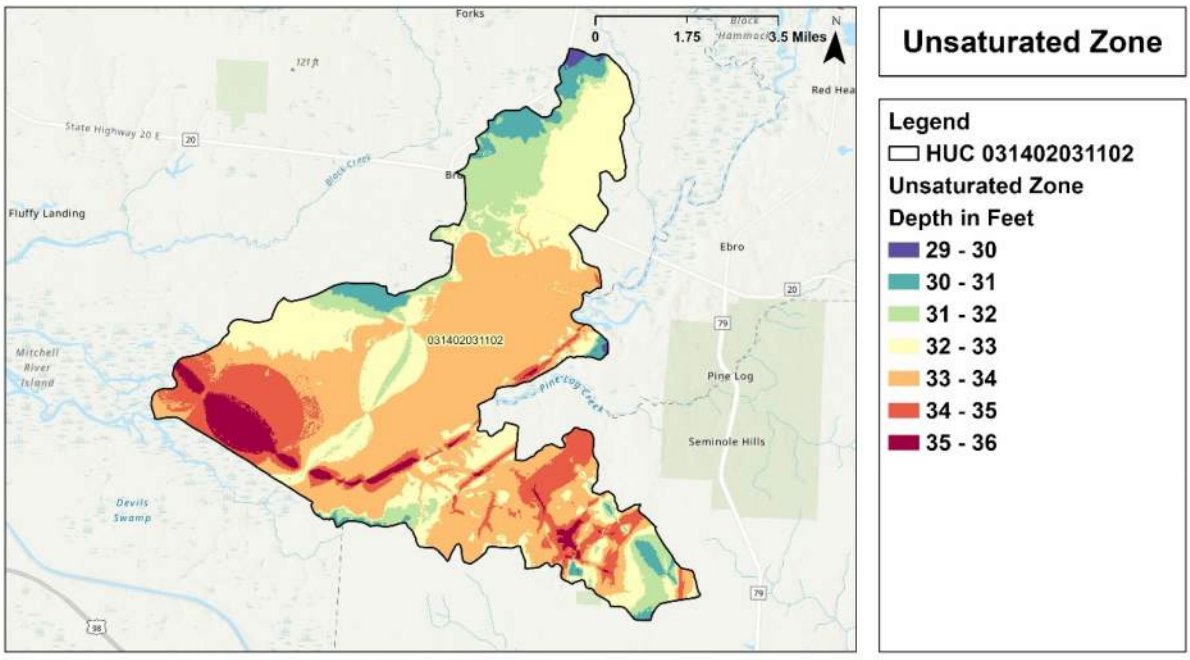

Figure 15. Unsaturated zone map for HUC 031402031102, processed by FAU.

The available water storage from USDA derived for the soil layer (0-150 cm or 0-5 ft) statewide is shown in **Error! Reference source not found.**, which covers most of Florida with a spatial resolution of 10 m. The unit is in cm. As a result of applying this layer to the study area (**Error! Reference source not found.**), the estimated soil storage capacity can be illustrated. A significant portion of the basin demonstrates a moderately favorable soil storage capacity, falling within the range of 31 to 35 feet of remaining capacity.

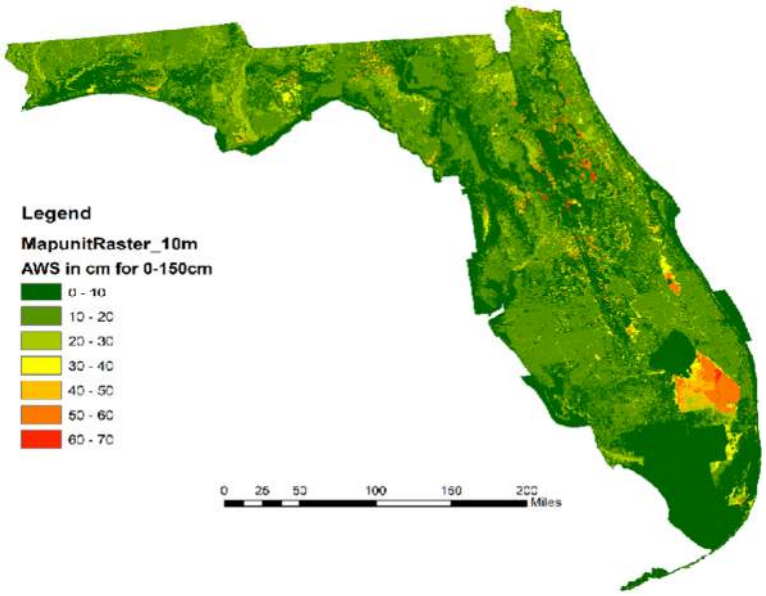

Figure 16. Available water storage derived from the gSSURGO soil database for all of Florida, as processed by FAU.
(Data Source: USDA - SSURGO)

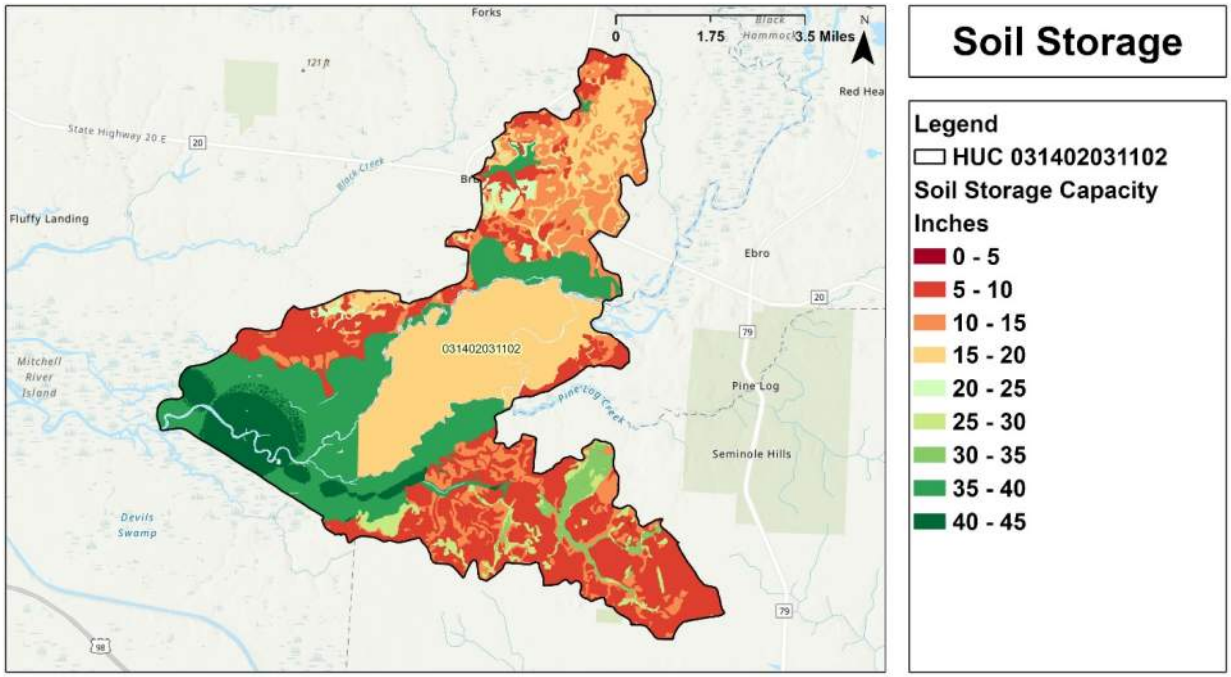

Figure 17. Water storage capacity of soil for the HUC 031402031102, processed by FAU.

Lastly, **Error! Reference source not found.** shows the water holding capacity for the basin, which refers to the capacity of a particular soil texture to retain water against the force of gravity.

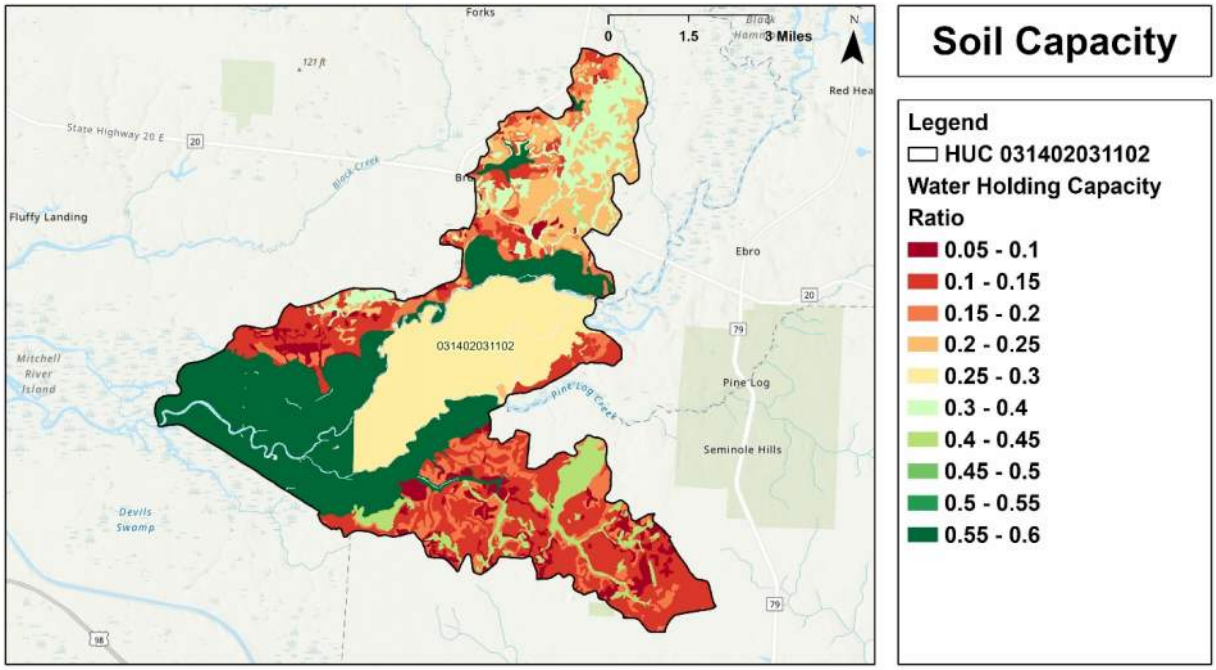

Figure 18: Water Holding Capacity (ratio) for the HUC 031402031102, processed by FAU.

1.5 Land Cover

The USGS produces the NLCD of nationwide data on land cover at a 30-m resolution with a 16-class legend based on a modified Anderson Level II classification system. NLCD is coordinated through the 10-member Multi-Resolution Land Characteristics Consortium (MRLC) to provide digital land cover information nationwide. For the conterminous United States, NLCD 2016 contains 28 different land cover products characterizing land cover and land cover change across 7 epochs from 2001-2016, urban imperviousness and urban imperviousness change across 4 epochs from 2001-2016, tree canopy and tree canopy change across 2 epochs from 2011-2016 and western U.S. shrub and grassland areas for 2016 (**Error! Reference source not found.**).

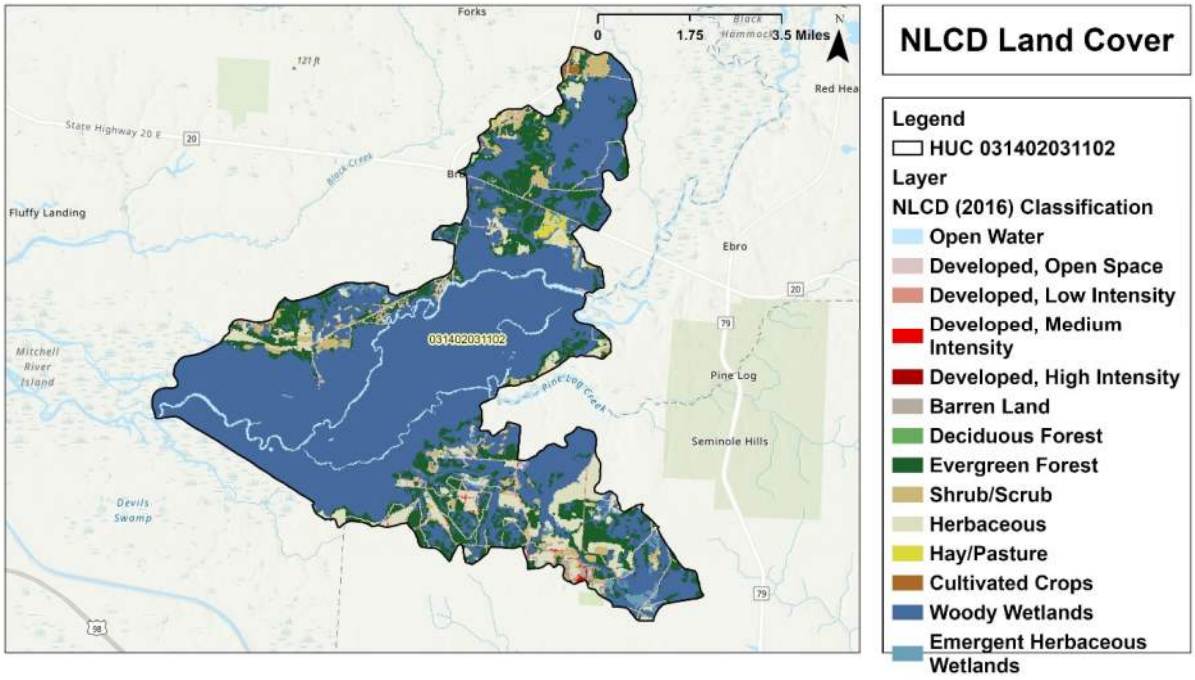

Figure 19. Land use in the HUC 031402031102 (from the NLCD 2016 database), processed by FAU.
(Source Data: NLCD, 2016)

The dataset is derived from the Florida Land Use Cover Classification System (FLUCCS), which is digitized by photo-interpretation on county-based aerial photography with varying resolution in the range of 4 in - 2 ft pixel. The NLCD2016 has a 30-meter resolution derived from Landsat imagery. Hence, the NLCD maps appear much coarser and pixelated compared to the 2023 Florida Geographic Data Library (FGDL) (https://fgdl.org/fgdlmap/) maps. A view of the latter is provided in **Error! Reference source not found.**. The future land use maps need to be used for the final land cover, as adjusted for future stormwater improvements set by regulatory standards.

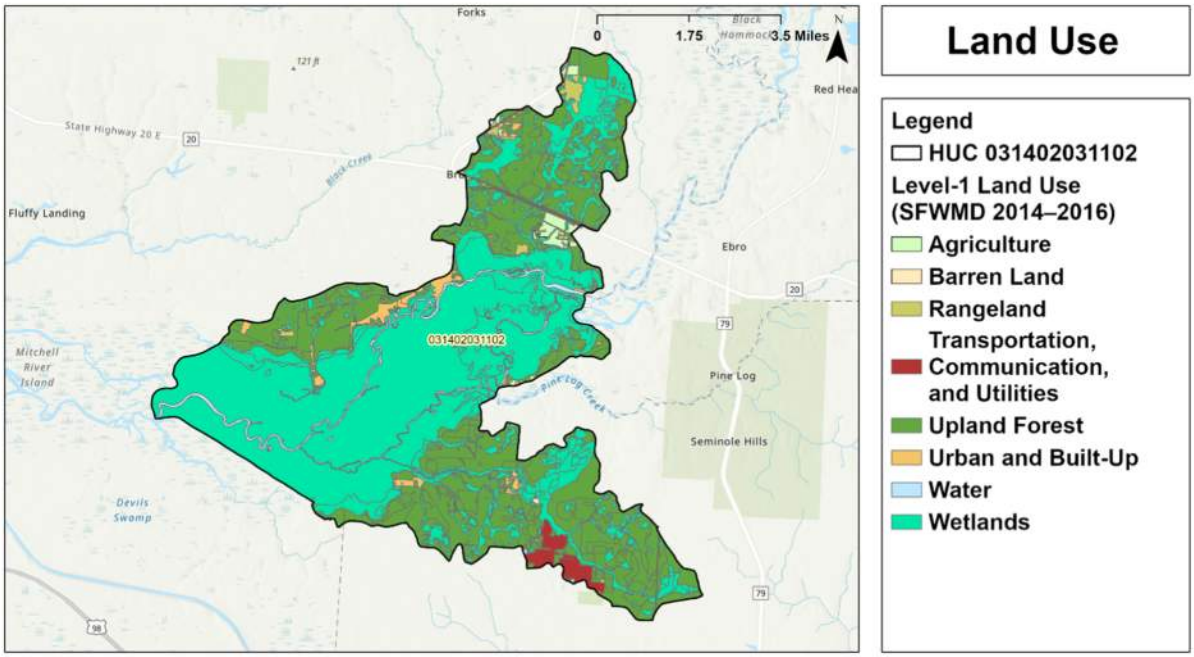

Figure 20. Land use in the HUC 031402031102, processed by FAU.
(Source Data: 2023 Florida Geographic Data Library (FGDL) database))

In the HUC 031402031102 sub-watershed, the predominant land cover is wetlands, accounting for 48.82% of the area. Upland forest comes in second at 32.99%, followed by Transportation, Communication, and Utilities at 8.05%. Developed land constitutes a minor portion, with only 1.20% categorized as urban and built-up, as indicated in **Error! Reference source not found.**. **Error! Reference source not found.** shows the roughness of the surface.

Table 3. Land use for HUC 031402031102 sub-watershed

Level 1 Land Use Land Cover Type	**Area (Acres)**	**Percentage of Total**
Agriculture	377.88	0.94%
Barren Land	6.83	0.02%
Rangeland	237.74	0.59%
Transportation, Communication, and Utilities	3236.46	8.05%
Upland Forest	13272.02	32.99%
Urban and Built-Up	483.61	1.20%
Water	2973.10	7.39%
Wetlands	19639.53	48.82%
Grand Total:	**40227.19**	**100.00%**

(Source Data: 2023 Florida Geographic Data Library (FGDL) database))

Table 4. Roughness and CN Values for Each Land Use Code

DOR Code	Use	Impervious %	Roughness
0	Vacant	0	0.4
1	Single Family	29	0.25
2	Mobile homes	21	0.05
4	Condos	60	0.05
7	Vacant –to be developed	0	0.4
8	Multifamily	60	0.05
TH 101	Townhomes	91	0.025
94	Road Right-of-Ways	50	0.08
	Open water	100	n/a
All others	Commercial, etc.	50	0.07

1.6 Precipitation

Rainfall used in the screening tool is based on the SFWMD 3-day 25-year storm, but can be modified for any rainfall event using the accumulated rainfall table obtained from NOAA Atlas 14 Point Precipitation Frequency Estimates (https://hdsc.nws.noaa.gov/hdsc/pfds/pfds_map_cont.html). **Error! Reference source not found.** shows the 3-day 25-year rainfall map based on the NOAA Atlas 14 dataset for the whole state. **Error! Reference source not found.** to **Error! Reference source not found.** rainfall 1-day 100-year, 1-day 10-year, and 1-day 5-year storm event scenarios, in inches.

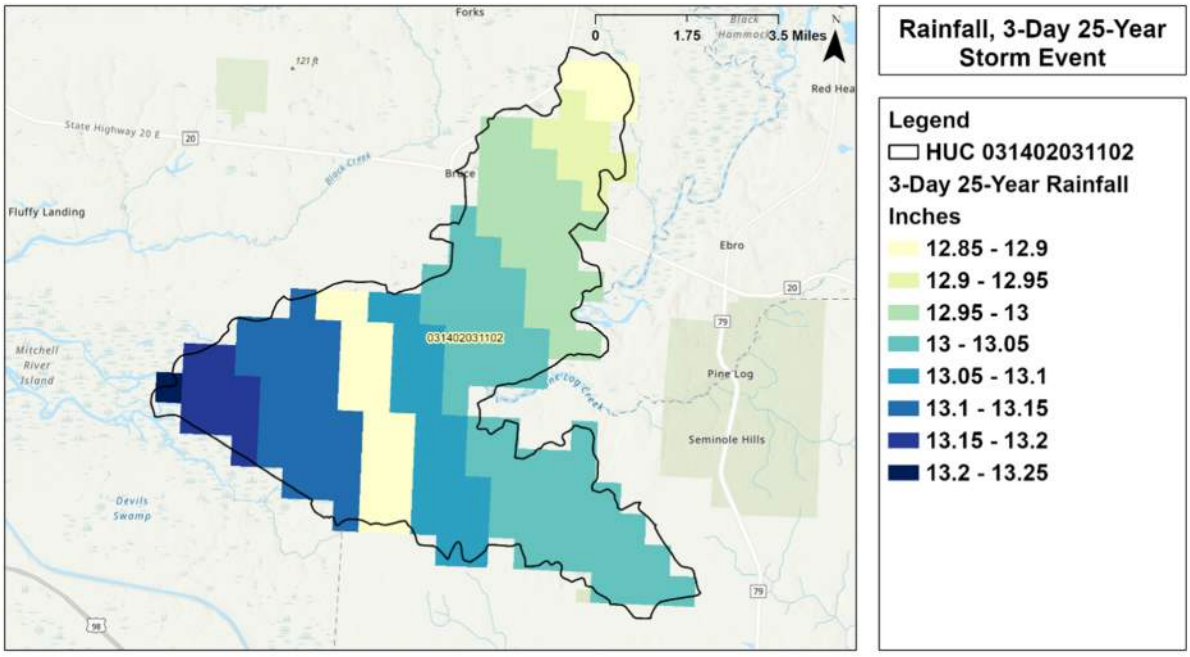

Figure 21. Rainfall distribution map across HUC 031402031102 sub-watershed, for 3-day 25-year storm event, processed by FAU.
(Source Data: NOAA Atlas 14 Database)

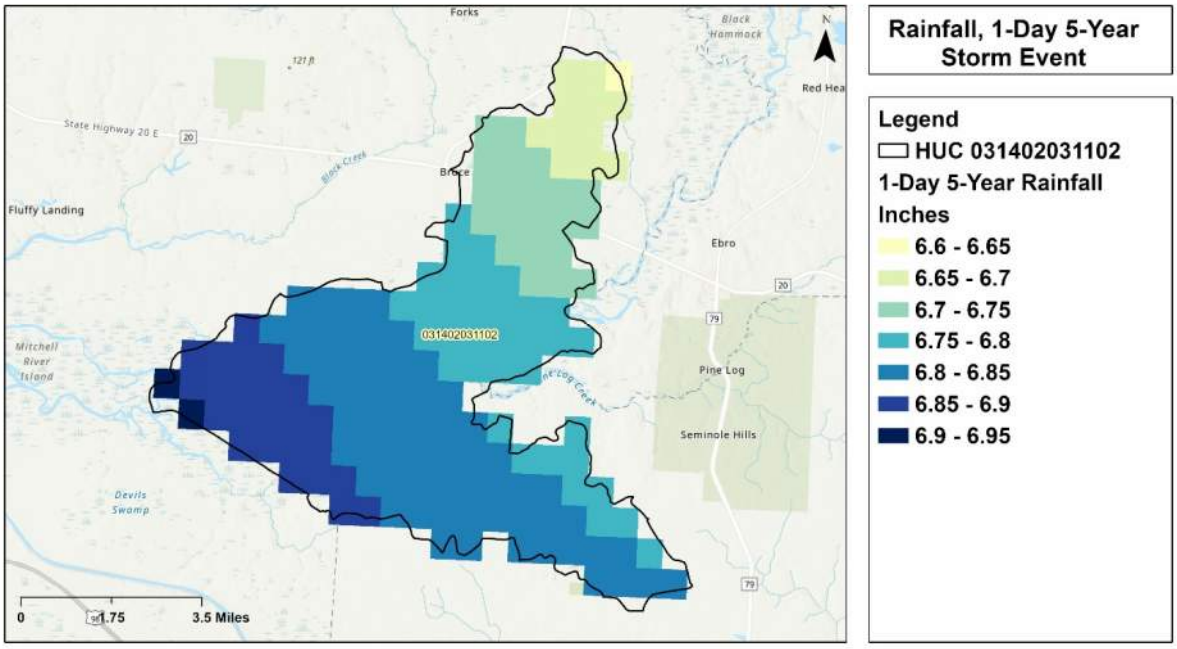

Figure 24. Rainfall distribution map across HUC 031402031102 sub-watershed, for 1-day 5-year storm event, processed by FAU.
(Source Data: NOAA Atlas 14 Database)

1.7 Open Space

Open space is defined as areas that are exempted from development. Generally, this means one or more of the following qualifiers exist:

1. Land that is valuable for recreation, forestry, fishing, or conservation of wildlife or natural resources
2. Land that is a prime natural feature of the state's landscape, such as a shoreline or ridgeline
3. Land that is habitat for native plant or animal species listed as threatened, endangered, or of special concern
4. Land that is a relatively undisturbed example of an uncommon native ecological community
5. Land that is important for enhancing and conserving the water quality of lakes, rivers, and coastal water
6. Land that is valuable for preserving local agricultural heritage
7. Proximity to urban areas or areas with open space deficiencies and underserved populations
8. Vulnerability of land to development
9. Stewardship needs and management constraints
10. Preservation of forest land and water bodies that naturally absorb significant amounts of carbon dioxide

Permanent protection of sensitive areas can provide critical water quality protection and can be achieved through partnerships with landowners, municipalities, land trusts and state agencies. There is limited land in the study area that has been protected via acquisition by federal, state or local agencies, has conservation easements or is designated as wetlands or areas of critical concern. Agricultural land and other land cover will come from the land cover map (in Section 1.5). Added to this will be the water bodies discussed in Section 1.9, which serve a related condition to open space.

1.8 Impervious Areas

Impervious areas do not permit the infiltration of rainfall to groundwater, and because the water cannot infiltrate, it runs off faster. Faster runoff means that flows to water bodies and storm sewers occur faster and with higher peaks. The result is a disruption of the natural and potentially the planned hydrology. Impervious areas include pavement, buildings, and other areas that reduce runoff capacity. In other words, developed areas have much higher imperviousness than open spaces that are natural or agricultural.

The NLCD provides nationwide data on land cover and land cover change at a 30-m resolution with a 16-class legend based on a modified Anderson Level II classification system. Systematically aligned over time, the database offers the ability to understand both current and historical land cover and land cover change to enable assessment of trends. Using the NLCD 2016 dataset, a layer was created by using only three categories out of the 13 to identify impervious areas such as primary roads in urban areas, secondary roads in urban areas, and tertiary roads in urban areas. The new layer was then converted to match the 3-meter spatial resolution from the DEM and the standard State Plane Coordinate system. **Error! Reference source not found.** shows the impervious areas derived from the NLCD 2016 as updated by the future land use map.

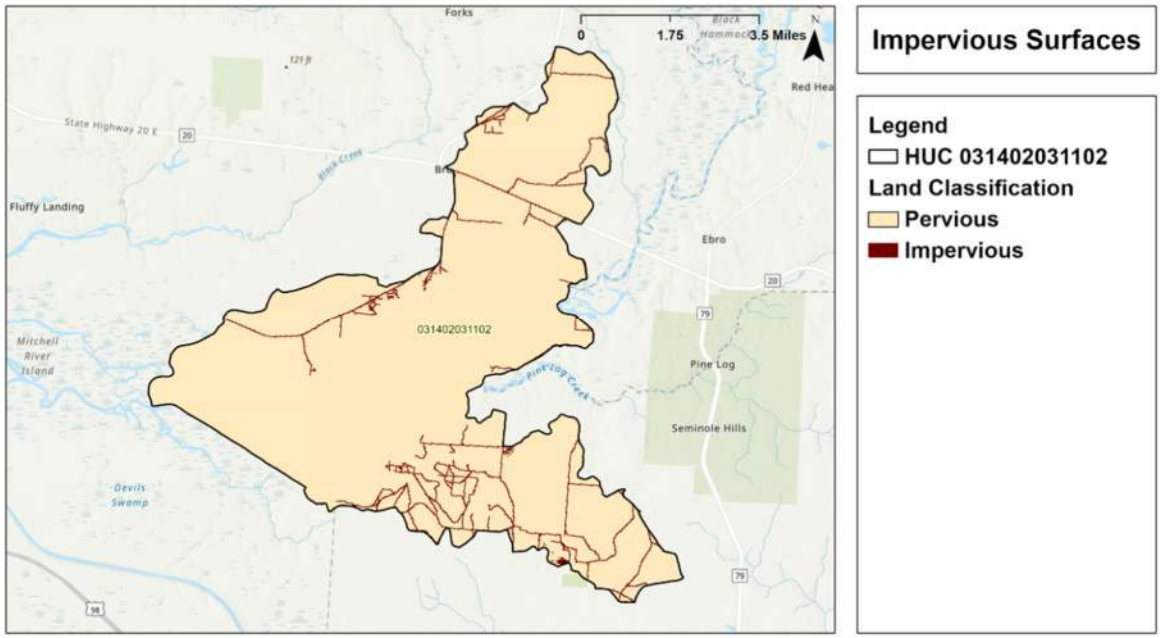

Figure 25. Impervious area map for the HUC 031402031102 sub-watershed, processed by FAU. (Source Data: NLCD, 2016)

1.9 Water bodies

Water bodies were defined in the statewide land use land cover dataset to set soil water holding capacity to zero in model simulations (**Error! Reference source not found.**). Note that tiny water bodies may be missing from the maps. Soils were discussed previously in Section 1.4.

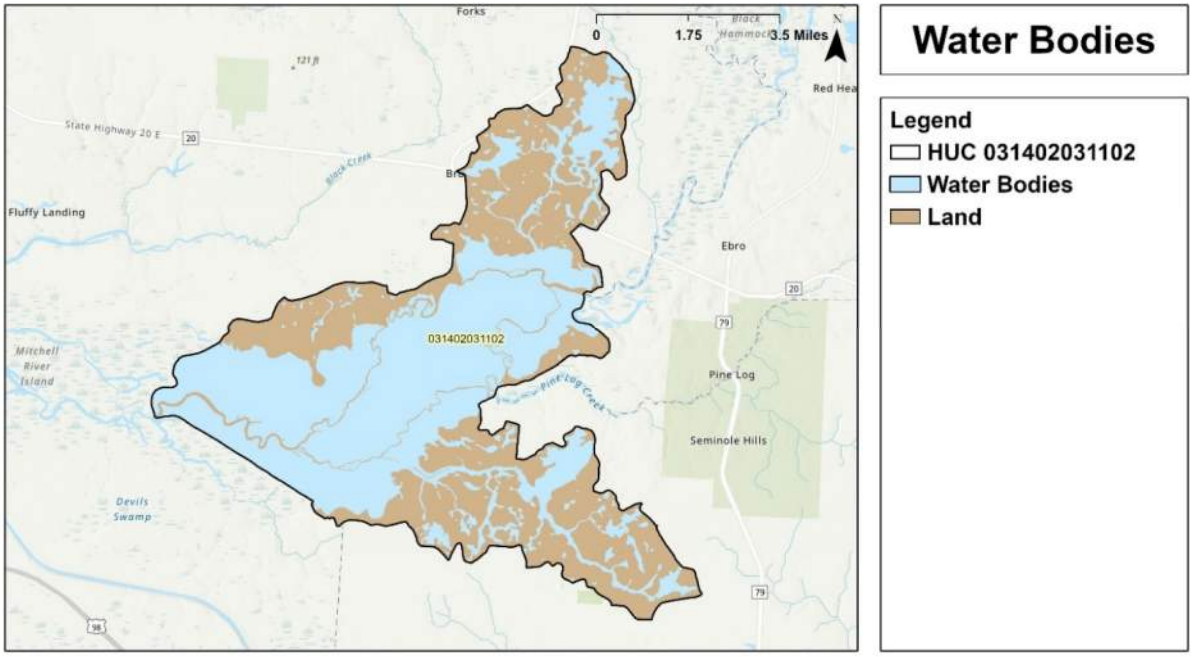

Figure 26. Water bodies map for the HUC 031402031102 sub-watershed, processed by FAU. (Source Data: USEPA – National Hydrographic Dataset (NHD))

1.10. Natural Resources

Understanding the study area's natural resources is critical to identifying potential sources of water quality degradation and areas to designate for conservation, protection, and restoration. One possible goal of watershed master planning is to protect terrestrial wildlife, aquatic habitat, and buffer zones. USGS maintains important sources of information on physical and geographical features as well as soil and mineral resources, surface and ground water resources, topographic maps, and water quality monitoring data. The USDA's Natural Resources Inventory (NRI) (www.nrcs.usda.gov/technical/NRI) is a survey of information on natural resources on non-federal land in the United States that captures data on land cover and land use, soil erosion, prime farmland soils, wetlands, habitat diversity, erosion, conservation practices, and related items. Since 2001, the NRI has been updated continually with annual releases of NRI data from all 50 states. The information provided can be used for addressing agricultural and environmental issues down to the county or cataloging unit level. Therefore, this data can be used to determine erosion and site-specific soil characteristics for certain land uses such as croplands, pasturelands, forestlands, etc., but the data is typically provided as inventories, not GIS layers.

1.11 Demographics

Demographics data is important for determining several key indicators for watershed master planning such as the ability to pay for improvements, social justice issues, land acquisition costs, property/land use, and communication strategies. The US Census has databases at the census tract level. Based on the census data for the study area, **Error! Reference source not found.** outlines population and racial composition demographics.

Table 5. Demographics and Housing Characteristics of Cities and Towns in Walton County.

Demographic Parameter	**Miramar Beach**	**Freeport**	**DeFuniak Springs, City**	**Paxton**	**Rosemary Beach**	**Santa Rosa Beach***	**Walton County**

** Census Designated Place

1.12 Stormwater Infrastructure Inventory

Local community stormwater systems consist of drainage ditches, storm sewers, retention ponds and other facilities constructed to store runoff or carry it to a receiving stream, lake, ocean, or other waterbody. Other man-made features include yards and swales that collect runoff and direct it to the sewers and ditches. When most of these systems were built, they were typically designed to handle the amount of water expected during a 10-year storm. Larger storms overload them, and the resulting backed-up sewers and overloaded ditches produce shallow flooding. Another urban drainage problem occurs in the areas protected by levees. Being in floodplains, they are flat and do not drain naturally, especially when a levee blocks the flow to the river. To drain these areas, channels have been built and pumps installed to mechanically move the water past the levee. Often, these man-made systems do not have the capacity to handle heavy rains or intense storms.

Another challenge with stormwater infrastructure is related to recordkeeping. It is not uncommon for stormwater data to be incomplete in most jurisdictions and completely lacking in others. Quality of data differs from jurisdiction to jurisdiction; some are in GIS formats, while others are paper maps or as-builts that represent the infrastructure at a macroscale level. The condition of the assets may be lacking, and the maintenance history may not be available either. Stormwater assets may have been installed with no records, especially in rural areas, farm fields, and private property.

Walton County passed Ordinance No. 2008-06 that prohibits unauthorized discharges into storm drains or ditch systems. In addition, the Public Works Division is currently running a continuous public awareness campaign aimed at encouraging the adoption of best management practices (BMPs) for managing stormwater runoff. This initiative targets both the business community and the residents of Walton County.

To address the issue of flooding, Walton County has implemented several measures along the years, such as:

- Drainage Systems: The county has invested in the development and maintenance of drainage systems, including ditches, canals, and retention ponds, to manage stormwater runoff and reduce flood risk.
- Floodplain Management: Walton County has adopted floodplain management regulations and participates in the National Flood Insurance Program (NFIP) to encourage responsible development in flood-prone areas.
- Elevation Standards: New construction projects within flood zones are required to adhere to specific elevation standards to minimize potential flood damage.

- Emergency Response: The county has established emergency response plans to assist residents during flood events, including evacuation procedures and the provision of emergency shelters.

Key stormwater assets for the HUC and Walton County are indicated in **Error! Reference source not found.** and **Error! Reference source not found.**, respectively. Stormwater structures and management processes in the county consist of stormwater outfall, water wells, weir, pollutant control boxes, inlets catch basins, pipes culverts, ditch conveyance swales, structures, pipes and open conveyance.

(Source Data: Walton County Storm Asset Inventory and Stormwater Inventory)

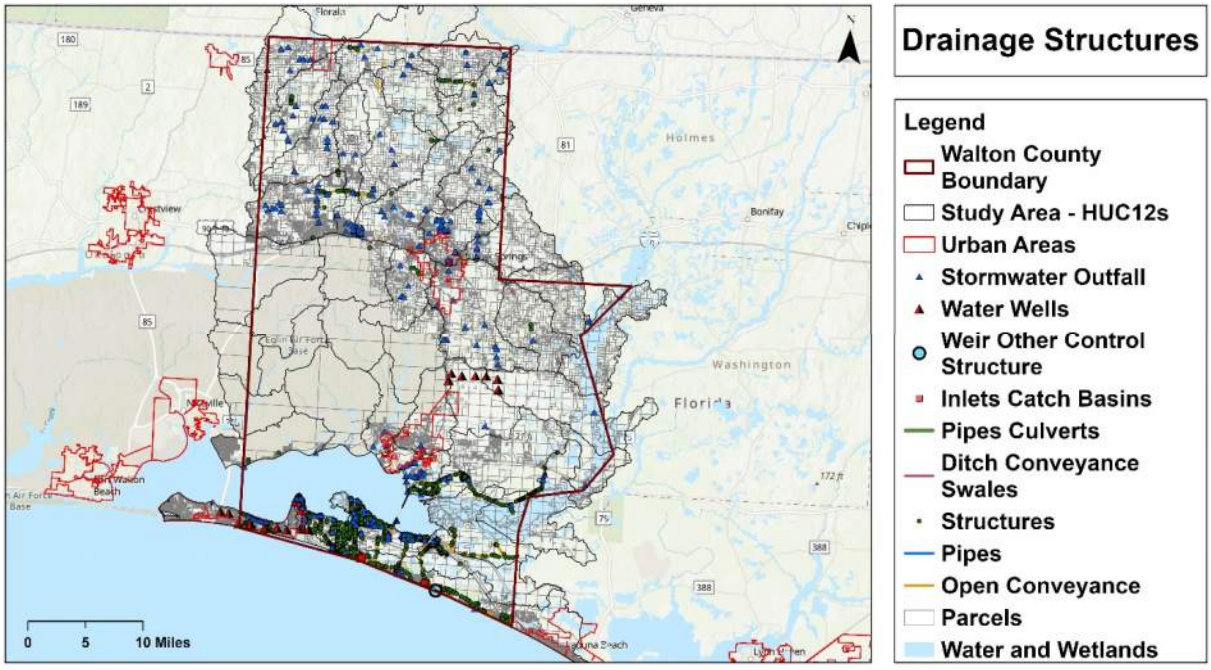

Figure 28.Stormwater Infrastructure for Walton County. Processed by FAU.
(Source Data: Walton County Storm Asset Inventory and Stormwater Inventory)

Although nature-based infrastructure might be installed, it is not certain. The stormwater system must maintain compliance with the stormwater regulations, which requires record-keeping, policy development, inspections and maintenance. The goals of such stormwater management may include:

- Best landscape practice;
- Control car washing contribution to pollution;
- Enforce the Stormwater Pollution Prevention Plan (SWPPP) by site evaluation, assessment, erosion and sediment controls, preventive maintenance, certification and inspection reporting for construction sites and city planning;
- Implement a hazardous material elimination system;
- Eliminate illicit dumping;
- Proactive and reactive catch basin inspections and maintenance;
- Street sweeping to control debris;
- Maintain swales to help prevent stormwater pollution flooding.

1.13 Data Gaps

FAU has developed comprehensive databases to address the information needed for the vulnerability assessment. These are included in Table 5. The data can be used to model the impacts

of flood routing during the storm of interest. As a result, the modeling pieces (discussed in Chapter 2) will include the following:

- Flood response model results (Cascade 2001)
- Flood risk/hazard mapping
- Vulnerability assessments to identify areas of concern for future repetitive losses

There is only one data gap for the area – existing stormwater infrastructure records are incomplete. However, for the purposes of this plan, this data gap does not limit the findings as there are two scales: 1) the sub-watershed level and 2) community hotspots. A neighborhood level vulnerability assessment will require the local infrastructure inventory.

Table 6. List of datasets collected by FAU as of List of datasets collected by FAU for the project (12/20/2020).

Data Category	Dataset Name	Original Source	Spatial Coverage/ Resolution	Temporal Coverage/ Resolution	Link to the Dataset on our Server (physical location)	Dataset size and Format	Native or FAU Processed dataset

2.0 ASSESSMENT OF VULNERABLE AREAS

Defining flood risk due to compounding hydrographic influences is the central concern of this WMP. Modeling and assessment of vulnerability focused on the combination of a high-water table, heavy rains, and impervious conditions that can lead to localized nuisance flooding events. Through a previous survey with local officials, the number of days of continuous nuisance flooding that the public will tolerate before that flooding is considered destructive is about 4 days (E Science 2014).

For a large study area, small parts may actually be at risk. The point is to identify where further study might be needed. A screening tool accomplishes this goal applied to the sub-watershed scale to designate areas that are susceptible to periodic flooding events. Utilizing the information collected and analyzed in Chapters 1, analysis of flood vulnerability can be performed.

2.1 Historical and Existing Challenges

Walton County has faced various historical and existing challenges as well as natural hazards over the years. Some of these include:

- Hurricane and Tropical Storms: being situated along the Gulf Coast, Walton County is vulnerable to hurricanes and tropical storms, which can lead to damage to the built and natural environment, as well as poses risks to human and wild life.
- Coastal Erosion: The county's coastline is subject to erosion due to natural processes and human activities. Erosion can lead to the loss of beaches and threaten coastal structures and properties.
- Flooding: heavy rainfall, storm surges from hurricanes, and other factors can cause localized flooding, particularly in low-lying areas. Flood events can disrupt daily life, damage property, and impact transportation.
- Water Quality and Quantity: as in many coastal areas, managing water quality and maintaining an adequate water supply are ongoing challenges. Pollution from stormwater runoff and other sources can affect water quality, and groundwater resources need to be carefully managed to sustain the growing population.
- Wetland Loss: The county's wetlands face the threat of degradation and loss due to urban development and other human activities. Protecting these essential ecosystems is vital for maintaining biodiversity and mitigating flood risks.
- Urbanization and Development: Balancing the demand for development and growth with the preservation of natural habitats and resources is a persistent challenge. Unplanned urbanization can lead to habitat destruction, increased runoff, and exacerbate flooding risks.

- Land Use and Zoning: Proper land use planning and zoning are essential to address issues related to population growth, infrastructure development, and natural hazard mitigation. Ensuring responsible development practices can help minimize risks.
- Invasive Species: Like many regions, Walton County faces the threat of invasive plant and animal species. These invasive species can disrupt local ecosystems, negatively impacting native flora and fauna.
- Sea-Level Rise: With rising sea levels due to climate change, coastal communities like Walton County's coastal areas are at greater risk of inundation and storm surges during extreme weather events.

The fast growth of the population and urban development in the coastal areas of the county exacerbates effort to protect open space for land percolation of water. While regulations are in place to reduce the influx of stormwater, the challenges will continue with development.

2.1.1 Existing Management Efforts in the Watershed

The county is under Northwest Florida Management District (NWFMWD) jurisdiction, which covers the Florida Panhandle region. The NWFMWD is responsible for managing and protecting water resources in its designated regions, which includes issues related to water supply, water quality, flood control, and natural resource conservation. Local governments have local stormwater utility infrastructure and planning/policy tools to reduce future flood potential. Most of the major projects to date have been focused on addressing the water quality issues and flooding due to extreme rainfall.

2.1.2 Critical Target Areas Identification

By modeling the HUC 031402031102 sub-watershed flood response to a series of rainfall events and sea levels (plus king tides), and further classifying flood risk as the probability of inundation, it is possible to identify critical target areas. These areas are particularly vulnerable to flooding and are subject to further study through a scaled-down modeling approach. The screening tool is first applied at the greater watershed level to provide an initial risk assessment focused on the hydrologic response to a rainfall event given the unique characteristics and features of the sub-watershed or study area. The process is discussed later in Section 2.2 with results presented in Section 2.4.

2.1.3 Potential Preservation Areas

Walton County boasts several areas with high biodiversity value. These areas include the unique coastal dune lakes, which support diverse ecosystems and contribute to water quality along the

coast. Wetlands are crucial habitats that provide refuge for a variety of plant and animal species while acting as natural water filters. State parks like Topsail Hill Preserve and Grayton Beach State Park are valuable conservation areas with diverse coastal ecosystems. Additionally, preserving the Choctawhatchee River Basin is essential for the biodiversity of the region.

2.2 Vulnerability Maps

2.2.1 Screening Tool

The screening tool utilizes topographic data from various sources (Section 1.1), water table elevations (Section 1.2) and surface water gauges (Section 1.3) downloaded from the NWFWMD DBHYDRO website, tidal information for coastal areas obtained from the NOAA Current & Tides website (Section 1.3), soil maps obtained from the USDA (Section 1.4), and another key dataset as described previously in Chapter 1. The design storms are discussed in Section 1.6. The reason this is critical is that to do any modeling (as required by the CRS program), a screening tool should be used to identify regions with a high risk of inundation based on multiple collected datasets and hydrological models. **Error! Reference source not found.** shows how the GIS layers interface in the tool and how they are combined for spatial analysis.

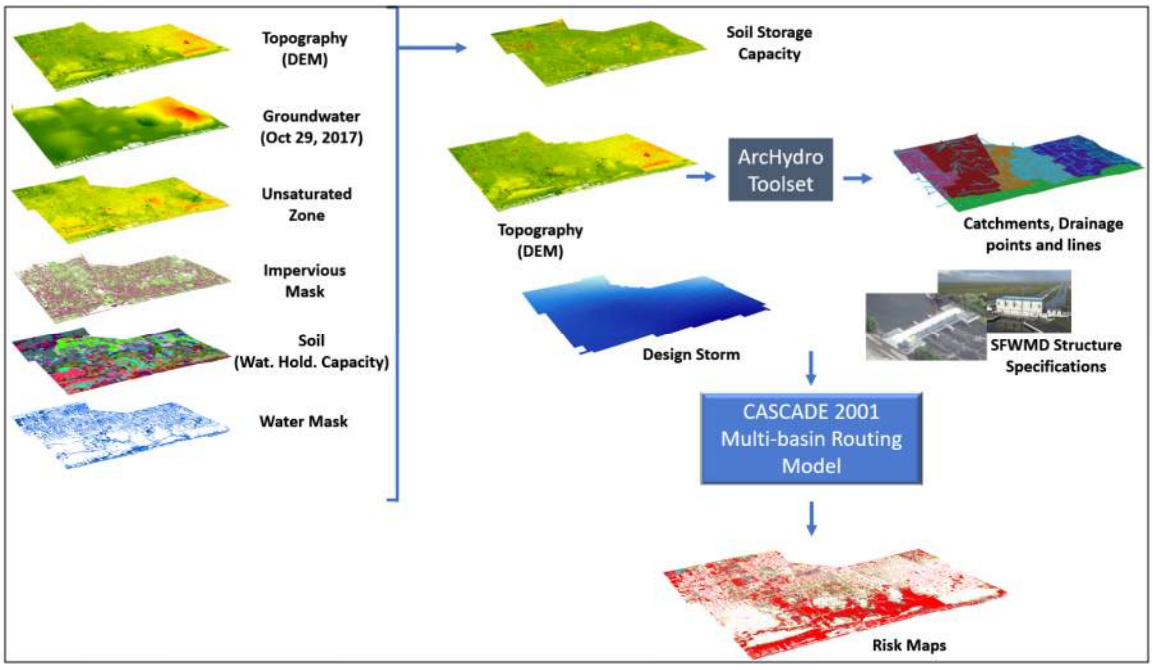

Figure 29. Screening tool methodology for creating flood risk maps.

The model chosen for this screening tool is Cascade 2001, which is a multi-basin hydrologic/hydraulic routing model developed by the SFWMD. The model permits the

investigator to run different storm events to determine flooding scenarios. The boundaries are critical for basin studies and must be chosen carefully. The following data layers collected in the prior section are processed to develop the input files for Cascade 2001:

- Topography
- Soils
- Development intensity
- Groundwater elevations
- Surface water/Outlet locations

The software creates a glass box where water rises to a certain level and then decreases. Running the simulation requires defining the basin (HUC or sub-HUC) and input of the following data:

- Area
- Portion of area above a given elevation
- Initial groundwater stage
- Longest travel time for the runoff to reach the most distance point of discharge
- Ground storage as estimated from the USDA gridded National Soil Survey Geographic Database (gNATSGO)

  Ground storage ≈ (Water holding capacity) × (Surface elevation – GW elevation)
  = 2 × (AWS for a soil layer of 0-150 cm) / 150cm × (Surface elevation – GW elevation)

- Available water storage (AWS) for a soil layer of 0-150 cm
- Average amount of precipitation that can be stored in the soil layer

The output from the model is an elevation surface that can be used to develop a flood map for the study area (**Error! Reference source not found.**), which shows the spatial distribution of probabilities of flooding during the modeled 1-day 100-year storm event.

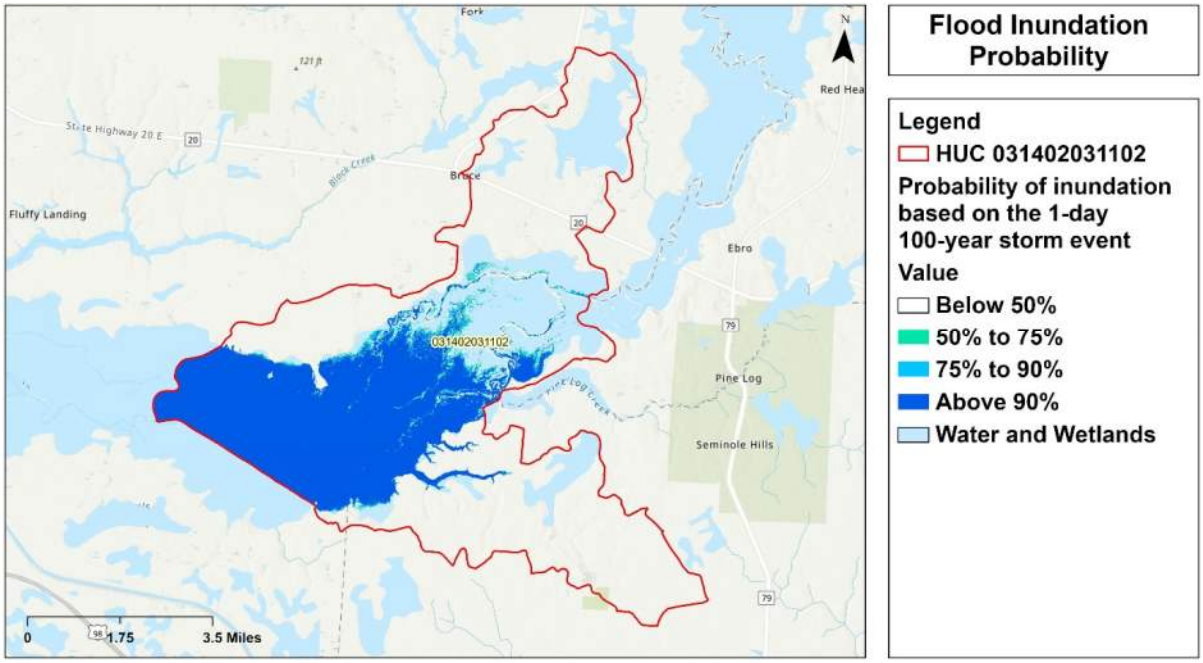

Figure 30. Probability of flood risk map during the modeled 1-day 100-year storm event for the HUC 031402031102, processed by FAU.

2.2.2 Identification of Vulnerable Areas

Given these assumptions and the Cascade 2001 outputs, the goal of this methodology is to produce a spatially-temporally quantified understanding of nuisance-destructive flood potential in the study area given observed values. Risk is a function of compounding geo-hydrological features, namely, surface water, groundwater, topography, build-out, and time of year. A GIS-based algorithm and spatial interpolation generated layers of the greatest observable hydrographic surfaces. These outputs were then compared with high resolution topographic LiDAR data to develop digital elevation models that reflect the observed risk landscape. These models can then be combined into Cascade 2001 to produce vector and volume information, in combination with soils, vegetation and impervious surfaces, allowing the observed model outputs to be extrapolated into a more predictive context.

To evaluate flood vulnerability at this scale, the analysis starts with a binary flooding surface (0 = below 50% chance of flooding; 1 = above 50% flooding) based on output from the screening tool for a specified design storm. Next, attributes of that raster based on "VALUE = 1" query are extracted using *Extract by Attributes* tool. Then the *Batch Project* tool was used to map critical facilities data to the common coordinate system (NAD83 UTM Zone 17N), unit = meters. Then a field was added using *Add Field* for [PriorityTier] = assigned Tier #1-4 value from the DOR codes and [Area_sqmeter]. The critical facilities layers were then merged into a single layer to calculate

the polygon geometry for [Area_sqmeter] using the *Merge* tool. Next, *Zonal Statistics as Table* is used to calculate the SUM of flooded values ("VALUE = 1") within each critical parcel. Output table has fields for SUM (i.e., total # of flooded pixels per critical parcel) and AREA in map units of square meters (since each pixel in the flooding surface has a cell size of 3-meters by 3-meters, each area is equal to the SUM value multiplied by 9 m^2). Using the *Join Field* tool, the SUM and AREA fields are joined to the merged critical facilities layer based on a key attribute, first renaming these fields for clarity (e.g., AREA_FLOODED_3d25y). Once all field data is included, the next step involves using *Export Table* to export the dataset as a CSV file. Note that non-flooded parcels have zero flooded area, so they receive a <Null> value from the zonal statistics tool. To replace null values with zeros, we use *Calculate Field* in the attribute table along with the following Python expression (replacing the respective field name): "0 if !AREA_FLOODED_3d25y! is None else !AREA_FLOODED_3d25y!". Next, the CSV file is saved as an Excel Workbook (.xlsx). The Range is converted to an Excel table, and the columns are rearranged in the desired order. Finally, the "percent-flooded" columns are calculated as follows:

- PCT_FLOODED_3d25y = ([@[AREA_FLOODED_3d25y]]/[@[TotalArea_sqmeter]])*100
- PCT_FLOODED_1d100y = ([@[AREA_FLOODED_1d100y]]/[@[TotalArea_sqmeter]])*100

After this calculation, the table is sorted to show the higher priority tiers and higher percent-flooded values first. To reduce the number of critical facilities shown in the final table, a filter was created to show only critical facilities with 10% or more flooded area in the parcel during both storm events. Records with duplicate parcel ID numbers were removed from the table. The results of this procedure are discussed in Section 2.5 of this document.

With respect to dams and levees, for purposes of the NFIP, FEMA only recognizes systems that meet, and continue to meet, minimum design, operation, and maintenance standards that are consistent with comprehensive floodplain management criteria. The Code of Federal Regulations, Title 44, Section 65.10 (44 CFR 65.10) describes the information needed for FEMA to determine if a levee system reduces the risk from the 1% annual chance flood. FEMA has accredited levees and Provisionally Accredited Levees (that have a specified timeframe to obtain the necessary data to confirm the levee's certification status). If a levee system no longer meets Section 65.10, FEMA will de-accredit the levee system and issue an effective FIRM showing the levee-impacted area as a SFHA. FEMA coordinates its programs with USACE, who may inspect, maintain, and repair levee systems. USACE has authority under Public Law 84-99 to supplement local efforts to repair flood control projects that are damaged by floods. Like FEMA, USACE provides a program to allow public sponsors or operators to address levee system maintenance deficiencies. Failure to do so within the required timeframe results in the levee system being placed in an inactive status in the USACE Rehabilitation and Inspection Program. Levee systems in an inactive status are not

eligible for rehabilitation assistance under Public Law 84-99. There are no levees/dams listed in the sub-watershed study area.

2.3 Future Challenges of Sea Level Rise and Climate Change

Global observations from satellites and long-term data collection have made it possible to document and analyze patterns in the Earth's climate. Scientific analysis of the impact of these changes has helped to improve the understanding of future flood hazard driving forces and long-term impacts on human activities and watershed master planning (http://www.research.noaa.gov/climate/t_observing.html). Examples of impacts are rising global average air and ocean temperatures, increased and earlier snow and ice melt, shorter subtropical rainy seasons, shifted seasons, sea level rise and greater variations in temperature and precipitation (IPCC, 2013; Freas et al., 2008; Marshall et al., 2004; Bloetscher et al., 2010). Marshall et al. (2004) specifically focused on the Florida peninsula to predict changes in rainfall and warmer temperatures but interspersed lower low temperatures due to the potential loss of wetlands.

Future changes in climate will add to the existing impacts, at a time when the population of the state is expected to nearly double by 2030. Additional research and high-resolution climate modeling for the Florida peninsula and local jurisdictions is needed to help guide long-term plans like WMPs. Rainfall appears to be decreasing and temperatures rising (see **Error! Reference source not found.**).

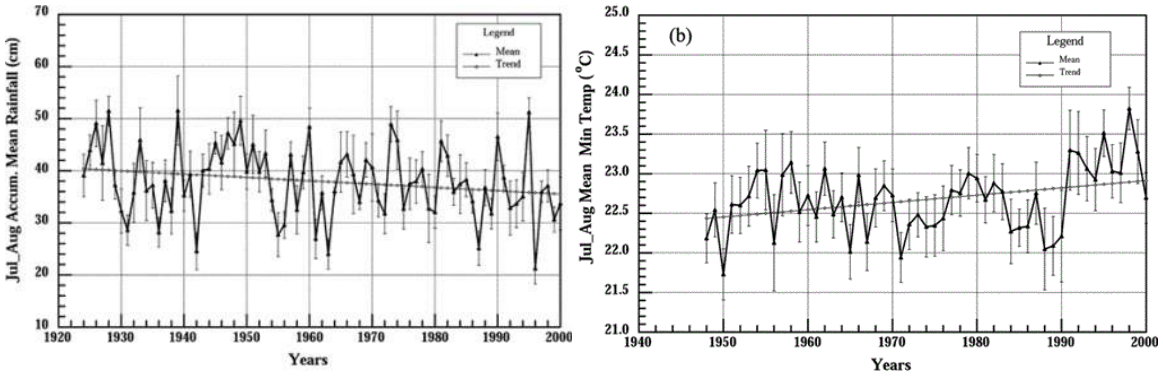

Figure 31. Change in average rainfall and change in average temp 1924 to 2000.
Note the reversed trend, which means groundwater input variability is lessened.
(Source: Marshall et al., 2004)

Climate change is likely to: 1) threaten the integrity and availability of fresh water supplies and 2) increase the risk of flooding, not only in the low-lying coastal areas, but also in the interior flood plains. Other issues include a) saltwater intrusion, which may be intensified by sea level rise, b) prolonged droughts that will contribute to water supply shortages and wildfires, and c) heavier rains during the rainy season and higher hurricane storm surge, which may increase the risk due to

flooding. More frequent and damaging floods are likely to become an ever-increasing problem as sea level continues to rise because of: a) increasing groundwater table elevations and surface water gage heights, b) reduced groundwater seepage through the aquifer to the ocean, c) increasingly compromised stormwater drainage systems, and d) more frequent inundation of barrier islands and coastal areas.

NOAA and IPCC (2013) predictions suggest that by 2100, global temperatures will be on the order of 2-3°C (3-5°F) higher and sea levels will rise by up to 3 feet. Accompanying these drivers are potential changes in storm frequency and intensity, desertification, population migration, ocean acidification and coastal flooding (IPCC, 2007), exacerbated by the land cover and land use changes, which are substantially impacted by the fluxes, timing and quality of precipitation (Adrians et al., 2003; Scanlon et al., 2005; Marshall et al., 2004; Salmun and Molod, 2006), and leading to changes in the timing of peak flows and volumes (Richey and Costa-Cabral, 2006).

The results of these climatic changes are likely to: 1) threaten the integrity and availability of fresh water supplies and 2) increase the risk of flooding, not only in the low-lying coastal areas, but also in the interior flood plains. Other issues include a) saltwater intrusion, which may be intensified by sea level rise, b) prolonged droughts that will contribute to water supply shortages and wildfires, and c) heavier rains during the rainy season and higher hurricane storm surge, which may increase the risk due to flooding. More frequent and damaging floods are likely to become an ever-increasing problem as sea level continues to rise because of: a) increasing groundwater table elevations and surface water gage heights, b) reduced groundwater seepage through the aquifer to the ocean, c) increasingly An outcome of these climatic patterns is that during the past 140 years, an increase in sea levels has been observed (Bloetscher, 2012), a worrying pattern since sea level rise is a permanent phenomenon, that can be catastrophic to low lying areas in the long-term. The question is how much and how soon? Various studies (Bindoff et al., 2007; Domingues et al., 2008; Edwards, 2007; Gregory, 2008; Vermeer and Rahmstorf, 2009; Jevrejeva, Moore and Grinsted, 2010; Bloetscher, 2010, 2011; IPCC, 2007; Heimlich et al., 2009) indicate large uncertainty in projections of sea level rise by 2100. Gregory et al. (2012) note that during the last two decades, the global rate of sea level rise has been larger than the 20th-century time-mean, and Church et al. (2011) suggested that the cause was increased rates of thermal expansion, glacier mass loss, and ice discharge from icesheets. Gregory et al. (2012) suggested that there may also be increasing contributions to global sea level rise from the effects of groundwater depletion, reservoir impoundment, and loss of storage capacity in surface waters due to siltation. Measurements of Florida's east coast (Maul, 2008) show an average rate of sea level rise of 2.27 ± 0.04 mm per year from 1915 to 1992 based on tide gauge readings. Analyzing the tidal gauge readings for Florida shows that:

1. Florida average sea level rise is 2.10 ± 0.49 mm/yr

2. All but one location is within the 95% confidence limit range (the exception is Panama City where there is evidence of submergence and other land-based issues)
3. None of the Florida sea level rise rates differ statistically
4. Average global sea level rise for 1920-2000 was 2.0 mm/yr – within 95% confidence limit for Florida locations

From 1929 to 1992, over eight inches of sea, with another 6 inches added since 1992, which is already having significant impacts on coastal communities where population growth has increased the need for improved flood management strategies (Bloetscher, 2008; Parkinson, 2010; Zhang et al., 2011, 2011a; NFIP, 2011; Schmidt et al., 2011; Warner et al., 2012).

As a result, the SFRCCC (2015) adopted USACE's methodology to derive scenarios of sea level change intermediate to high rates of sea level rise for years 2030 (3" to 7") and 2060 (9" to 24") as the consensus projection to guide future planning. The path keeps increasing – now 14 inches since 1929 (**Error! Reference source not found.**) caused by thermal expansion of the ocean and melting ice caps (Jevrejeva et al., 2010; Vermeer and Rahmstorf, 2009). Sea level rise is a major concern in Florida, including Walton County, since the majority of the state's population live on the coast, involving most major commercial, residential, and economic enterprises. **Error! Reference source not found.** demonstrate the estimated sea level change for Panama City, considering the predictions of NOAA 2017. For NOAA high scenario SLR change scenario, the estimated level change is higher than 8 ft., while for the intermediate and low scenarios are about 3.9 feet and 1.7 feet respectively.

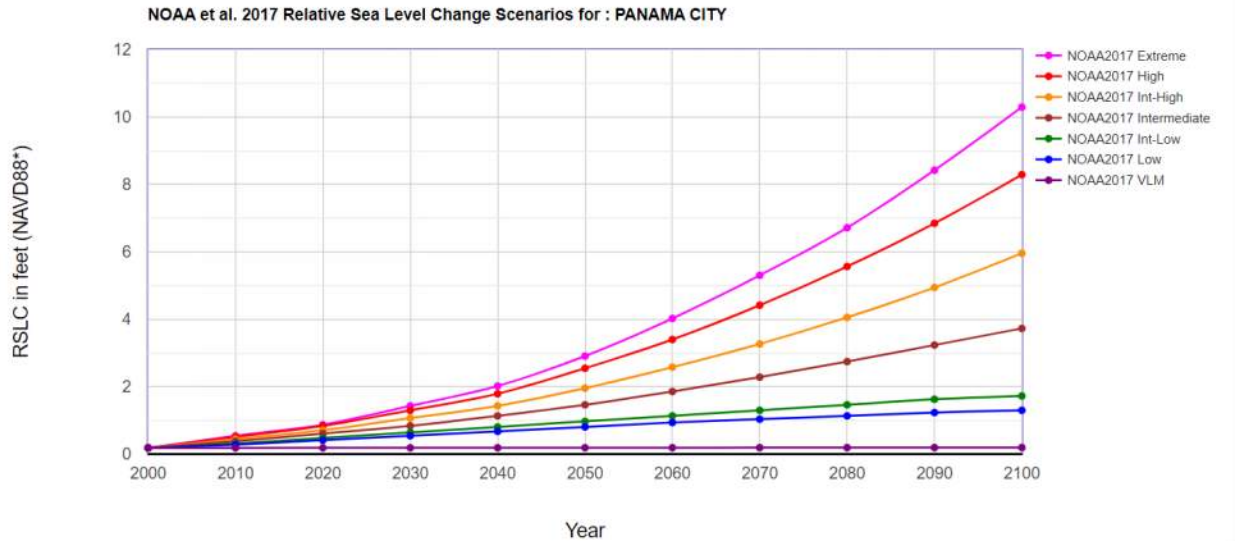

Figure 32. Relative Sea Level Change Scenarios for gauge 8729108, Panama City, FL. (Source: NOAA, 2017 available at https://cwbi-app.sec.usace.army.mil/rccslc/slcc_calc.html)

NOAA (2017) outlines five scenarios for sea level rise. The NFIP proposes the use of the intermediate high projection, which is 1.2 meters or 4 ft globally from current sea level elevations (**Error! Reference source not found.**).

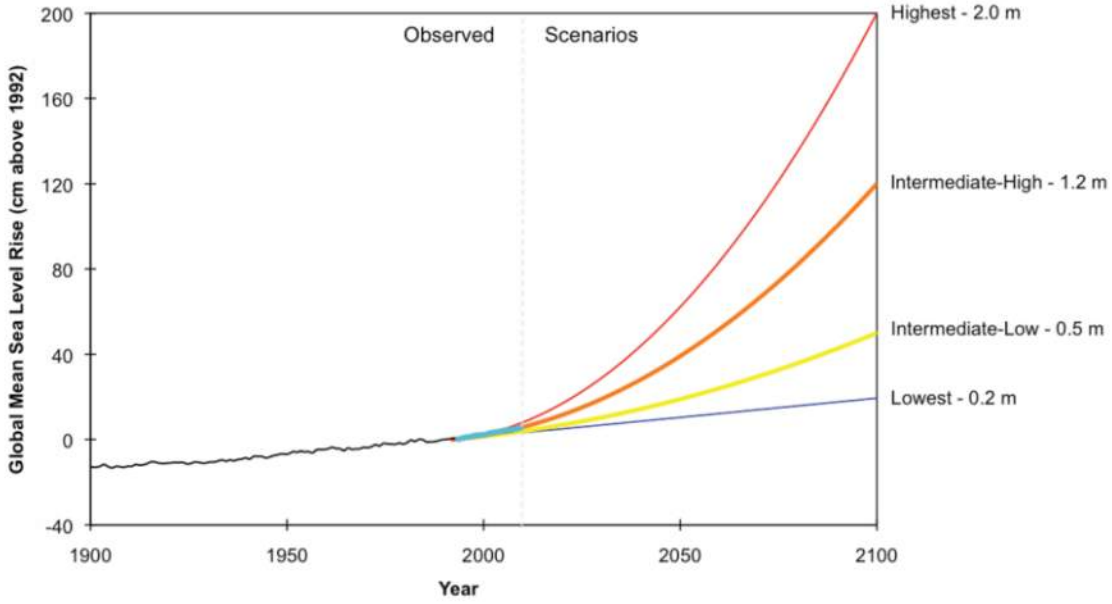

Figure 33. Graphic of global sea level rise projections from NOAA (2017).
(Source: NOAA, 2017 available at https://tidesandcurrents.noaa.gov/publications/techrpt83_Global_and_Regional_SLR_Scenarios_for_the_US_final.pdf)

As sea level rises, access to roads, bridges, rail, and transit could be at risk of flooding, causing the effects of sea level rise to spread indirectly throughout the entire transportation network, affecting the overall system performance. For example, the flooding of a critical road or facility access can cause a shifting of traffic flow causing congested conditions in other roadways that are not actually flooded. Since the roadway network would be unable to carry the traffic demand, the system would experience operational failure; as a result, causing travel times and delays. Moreover, the inundation of a critical access could cause transportation connectivity problems to essential infrastructure like ports or airports. Transportation infrastructure relies on the effectiveness of flood control and stormwater drainage systems for the transportation corridors. Road integrity relies on adequate drainage. The increased risk of severe flooding in Florida's low-lying terrain can adversely affect transportation infrastructure along the coastline; roads can be inundated, and roadway beds can be damaged. Sea level rise will cause increased water table levels (FDOT, 2012), as regional water tables cannot exist naturally below mean high tide (2 feet in Florida). Adding 3 feet of sea level rise on top of groundwater would compound the risk of flooding in low-lying areas. Road bases below 5 feet NVGD would become saturated under this scenario, likely causing premature base failure. As soil storage capacity is diminished due to rising groundwater elevations associated with sea level rise, the potential for more frequently flooded

roadways would likely damage pavements (FDOT, 2012). Hence sea level rise must be accounted for in WMPs in coastal areas. To allow flexibility in the analysis due to the range of increases within the different time periods, an approach that uses incremental increases of 1, 2, and 3 feet of sea level rise is suggested for modeling. The increments can work as threshold values in planning considerations in terms of allowing planners the ability to know ahead of time where the next set of vulnerable areas will be, to allow for a proactive response approach that can be matched to the observed future rates. Sea level rise is a major concern since nearly half the US population lives within 50 miles of the coast, involving most major commercial, residential, and economic enterprises. The effects of 5 ft sea level rise, King tide, and 1-day 100-year storm event are shown in in Figure 34.

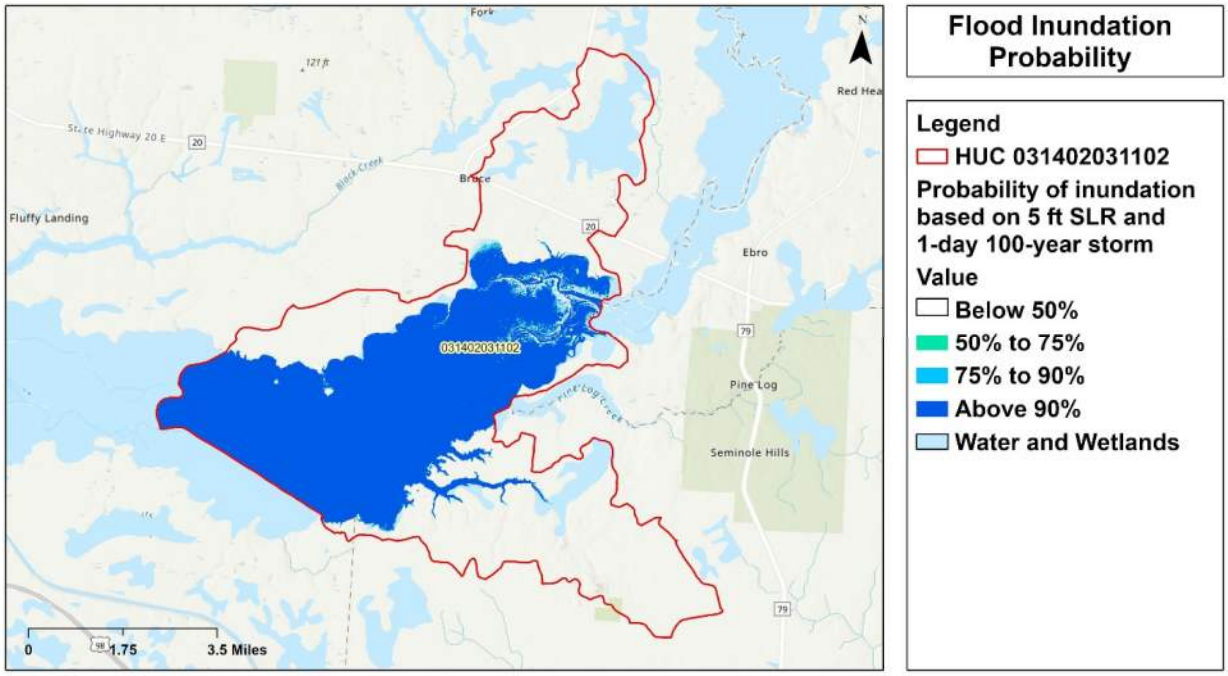

Figure 34. Flood Inundation Probability for a Sea level rise of 5 ft + 1-day 100-year storm event for HUC 031402031102 sub-watershed.
Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations.
Dark blue is area under 5 ft NAVD88 and potentially inundated at the 99th percentile tidal conditions. Processed by FAU.

2.4 Modeling Results

Error! Reference source not found. to **Error! Reference source not found.** are a series of maps that depict risk of flooding in the basin based on the following scenarios:

1. **3-day 25-year storm event**. Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 35)
2. **1-day 100-year storm event**. Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 36)
3. **1-day 10-year storm event.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 37)
4. **1-day 5-year storm event.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 38)
5. **Sea level rise of 1 ft + 3-day 25-year storm** (only coastal area and GW affected – GW layer rises 1 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 39)
6. **Sea level rise of 1 ft + 1-day 100-year storm** (only coastal area and GW affected – GW layer rises 1 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations storm (Figure 40)
7. **Sea level rise of 1 ft + 1-day 10-year storm** (only coastal area and GW affected – GW layer rises 1 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 41)
8. **Sea level rise of 1 ft + 1-day 5-year storm** (only coastal area and GW affected – GW layer rises 1 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 42)
9. **Sea level rise of 2 ft + 3-day 25-year storm** (only coastal area and GW affected – GW layer rises 2 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 43)
10. **Sea level rise of 2 ft + 1-day 100-year storm** (only coastal area and GW affected – GW layer rises 2 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 44)
11. **Sea level rise of 2 ft + 1-day 10-year storm** (only coastal area and GW affected – GW layer rises 2 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 45)
12. **Sea level rise of 2 ft + 1-day 5-year storm** (only coastal area and GW affected – GW layer rises 2 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 46)
13. **Sea level rise of 3 ft + 3-day 25-year storm** (only coastal area and GW affected – GW layer rises 3 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 47)
14. **Sea level rise of 3 ft + 1-day 100-year storm** (only coastal area and GW affected – GW layer rises 3 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 48)

15. **Sea level rise of 3 ft + 1-day 10-year storm** (only coastal area and GW affected – GW layer rises 3 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 49)
16. **Sea level rise of 3 ft + 1-day 5-year storm** (only coastal area and GW affected – GW layer rises 3 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 50)
17. **Sea level rise of 4 ft + 3-day 25-year storm** (only coastal area and GW affected – GW layer rises 4 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 51)
18. **Sea level rise of 4 ft + 1-day 100-year storm** (only coastal area and GW affected – GW layer rises 4 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 52)
19. **Sea level rise of 4 ft + 1-day 10-year storm** (only coastal area and GW affected – GW layer rises 4 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 53)
20. **Sea level rise of 4 ft + 1-day 5-year storm** (only coastal area and GW affected – GW layer rises 4 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 54)
21. **Sea level rise of 5 ft + 3-day 25-year storm** (only coastal area and GW affected – GW layer rises 5 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 55)
22. **Sea level rise of 5 ft + 1-day 100-year storm** (only coastal area and GW affected – GW layer rises 5 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 56)
23. **Sea level rise of 5 ft + 1-day 10-year storm** (only coastal area and GW affected – GW layer rises 5 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 57)
24. **Sea level rise of 5 ft + 1-day 5-year storm** (only coastal area and GW affected – GW layer rises 5 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 58)

In all scenarios, a great amount of flooding is noted at the river entrance to the HUC, extending to the wetland areas. As this basin connects to the ocean though Choctawhatchee River, SLR scenarios plays an important hole, implying a considered growth as the projected scenario of rising tides rises.

The design storm simulation determined that approximately 32% of the HUC total area or 14.13 mi^2 has a probability of inundation above 50% for a 3-day 25-year design storm. For comparison, approximately 32.2% of the HUC's total area, or 14.24 mi^2 would be expected to be inundated during a 1-day 100-year design storm. Approximately 31.7% of the HUC's total area,

or 14.01 mi², would be expected to be inundated during a 1-day 10-year design storm. Finally, approximately 31.7% of the HUC's total area, or 14.01 mi², would be expected to be inundated during the 1-day 5-year storm. **Error! Reference source not found.** compares the four storm events.

Table 7. HUC 031402031102 expected inundated area by storm event.

Storm Event	Area with probability of inundation below 50% (Sq Mi)	Area with probability of inundation above 50% (Sq Mi)	Area with probability of inundation below 50% (%)	Area with probability of inundation above 50% (%)
3-day 25-year	30.07	14.13	68.0%	32.0%
1-day 100-year	29.96	14.24	67.8%	32.2%
1-day 10-year	30.19	14.01	68.3%	31.7%
1-day 5-year	30.19	14.01	68.3%	31.7%

2.5 Risk and Vulnerability

The screening tool modeling exercise from the prior section identified areas within the communities that are vulnerable to flooding. Higher priority concerns should be those properties or assets that are considered essential and need to be kept in service during a flooding event. All other improvements are local. To help with prioritization, the following is suggested:

- Tier 1 - Critical facility protection (water/sewer utilities, public safety, hospitals, schools, power, shelters)
- Tier 2 - Essential facilities (groceries, pharmacies, roadways)
- Tier 3 - Economic centers (protecting jobs)
- Tier 4 - At risk communities
- Tier 5 - Other urban/suburban property
- Tier 6 - Agriculture/public property/vacant/undeveloped

Error! Reference source not found. outlines the priority of land use based on DOR land use codes from the property appraiser's office and assigns an associated priority level to each parcel. Note that for residential property, identifying at-risk communities (income, age, disability, health)

requires a further drilldown to the neighborhood level (i.e. wealthy neighborhoods with few older, poor health individuals would have a lower priority than at risk communities, which generally have lower value housing and denser development). In the latter case, more people are impacted, and those people have less ability to mitigate risk. Based on these priorities, the relative risk priority DOR land use codes were evaluated based on a scale of 1 to 6, where 1 is higher priority (more vulnerable) and 6 is the least priority (least vulnerable).

Table 8. Priority of Land Use based on (DOR) land use codes. Processed by FAU.

DOR (Use code)	**Description**	**TIER (Priority of Land Use)**
0	Vacant Residential	6
1	Single Family Residential	5

97	Outdoor Recreational Or Parkland, Or High-Water Recharge Subject To Classified Use Assessment	6

98	Centrally Assessed	6
99	Other Non-Agricultural Acreage	6
100	Parcel With no Values	6
101	Parcels With no Values (ROW - avenues, highways, arterials)	2
102	Parcels With no Values (Water)	6
103	Parcels With no Values (Rail)	2

Having assigned the risk priority from 1 to 6 in the DOR codes and the percentage of the parcel that floods during the applicable design storm, properties that are more critical to the function of the community can be identified. The methodology is to first convert the DOR code priority tier to its inverse scale by the following equation:

Consequence of risk factor = 7 – DOR Code Priority Tier

The flood risk factor from the screening tool is interpreted based on flooding probability. We take all parcels in tiers #1-4 that have a greater than 50% chance of flooding during a particular design storm and calculate the percent of the parcel that would flood during that event. The percentage is converted to a 6-point scale termed as the Flood Risk Factor, shown in **Error! Reference source not found.**.

Table 9. Flood Risk Factor Classification.

Percent of Parcel Flooded	Flood Risk Factor
90-100%	6
80-89%	5
70-79%	4
60-69%	3
50-59%	2
<50%	1

The priority is further developed by assigning 75% of the importance to the consequence of flooding and 25% importance to flood risk, or three times the importance to the consequence of flooding to come up with a composite score as follows:

Flood Risk Factor × 25% + Consequence of Risk Factor × 75% = Composite Score

Example: 1 × 25% + 6 × 75% = 4.75

Those higher priority properties that received the higher composite score are where the mitigation strategies and financial resources should focus first.

2.5.1 Results

Error! Reference source not found. to **Error! Reference source not found.** depict the HUC 031402031102 sub-watershed priority of land uses showing the critical facilities that should receive priority. The first map (Figure 59) exclusively displays critical facility parcels within the HUC without any flooding. The first map (**Error! Reference source not found.**) exclusively displays critical facility parcels within the HUC without any flooding. The second map (Figure 60) overlays critical facilities onto the 1-day 100-year storm event scenario, while the third map (**Error! Reference source not found.**) represents the same overlay within the context of 5 feet of sea level rise (SLR) combined with the 1-day 100-year storm event. **Error! Reference source not found.** is a mosaic showing critical facilities overlaid in the 5 feet SLR + 1-day 100-year storm event for the whole county.

Additionally, **Error! Reference source not found.** and **Error! Reference source not found.** illustrate the composite score for the HUC, which is the result of the calculations explained above, pinpointing parcels that should be prioritized. It considers only parcels classified as 1 to 4 tiers, and within the 50% probability of inundation area. **Error! Reference source not found.** represents the calculation for composite score based on 1-day 100-year storm event, while **Error! Reference source not found.** shows the calculation for composite score for the same storm event, but including a 5 feet of Sea Level Rise scenario. **Error! Reference source not found.** shows the same area zoomed out.

Please note that the composite score results display outcomes exclusively for parcels within the flooding path area. Consequently, for parcels outside this flooding path, the composite results will be null. The composite score combines the flooding path area with the land use priority results to identify the most vulnerable areas deserving of priority.

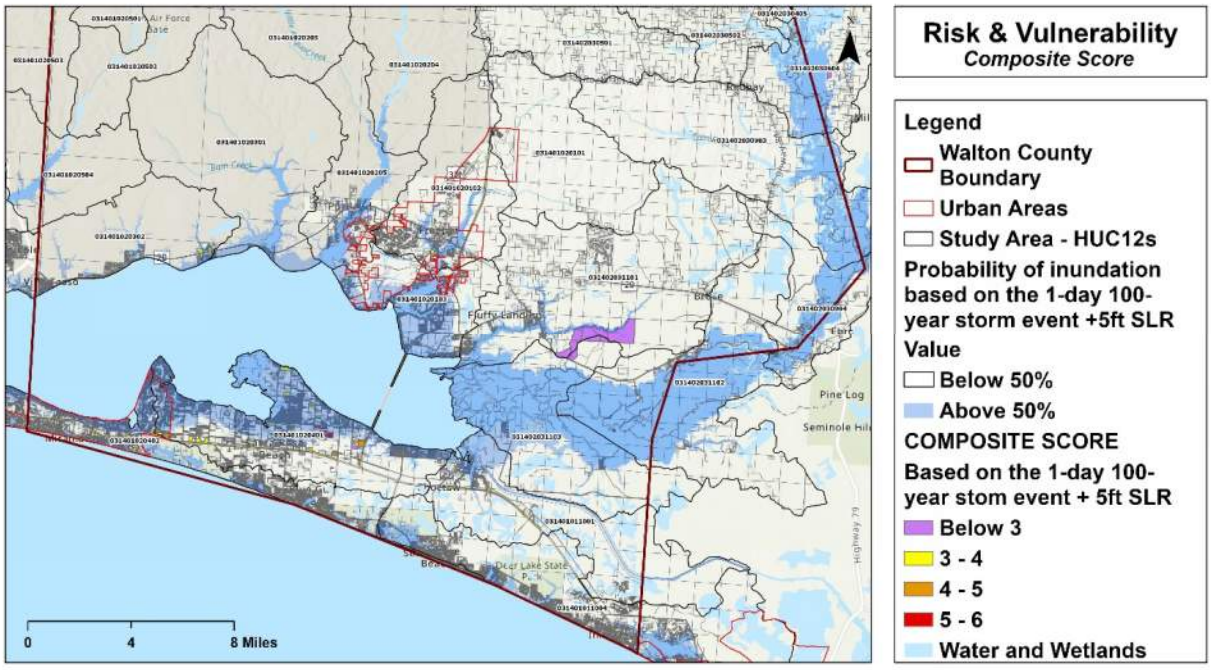

Figure 65. Coastal Area of Walton County (mosaic) - Composite Score Risk map overlaid on the 1-day 100-year + 5 ft. SLR storm event probability of inundation. Processed by FAU.

2.5.2 Solutions

Chapter 5 of the Watershed Master Plan for Walton County describes a list of possible gray and green stormwater strategies to combat flooding that can be implemented as solutions for the county. The same solutions can also be applied at the HUC level, including HUC 031402031102. A summary of these flood mitigation strategies is listed in **Error! Reference source not found.**. For more detailed information, please see Chapter 5-5.3 (Solutions).

Table 10. List of possible gray and green stormwater strategies to combat flooding.

Strategy Class	Implementation Strategy	Applications	Benefits	Cost	Barriers to Implementation
Green	Rainwater harvesting	Local, small scale, easily implemented in developed areas	Protects property, treats runoff	Under $5,000	Limited volume disposed of, so many are needed, maintenance
Gray	Pervious paving	Parking lots, patios, driveways, anything except paved roads due to traffic loading	Reduces roadway and parking lot flooding	$10-20/sf, requires bumpers and sub-base to maintain paver integrity	Must be maintained via vacuuming or the perviousness fades after 2-3 years
Green	Detention	Common for new development, but difficult to retrofit; limited to open areas	Removes water from streets, reduces flooding	$200K/ac	Land availability, maintenance of pond, discharge location Uses up land that could otherwise be developed
Gray	Exfiltration Trench	Any low-lying area where stormwater collects and the water table is more than 3 ft below the surface; densely developed areas where retention is not available, roadways	Excess water drains to aquifer, some treatment provided	$250/ft	Significant damage to roadways for installation, maintenance needed, clogging issues reduce benefits
Gray	Central sewer installation	All areas where there are septic tanks. Mostly a water quality issue	Public health benefit of reducing discharges to lawns, canals, and groundwater from septic tanks	$15,000 per household	Cost, assessments against property owners, property rights issues

Strategy Class	Implementation Strategy	Applications	Benefits	Cost	Barriers to Implementation
Green	Flood prone property acquisition	Regional agency - could be any low-lying areas	Removes flood prone areas from risk	$2K-$100K/ac depending on whether it is already developed	Difficult to implement if occupied, issues with willing sellers, cost, lack of funds for acquisition
Gray	Pump stations	Any low-lying area where stormwater collects, and there is a place to pump the excess stormwater to such as a canal; common for developed areas	Removes water from streets, reduces flooding	Start at $1.5 to 5 million each, number unclear without more study	NPDES permits, maintenance cost, land acquisition, discharge quality
Gray	Armored sewer systems	Any area where gravity sanitary sewers are installed	Keeps stormwater out of sanitary sewer system and reduces potential for disease spread from sewage overflows	$500/manhole	Limited expense beyond capital cost
Gray	Sea walls	Barrier islands and downtown coastal areas	Protects property	$1200/ft	Private property rights, neighbors
Policy	Changes in land use	Applicable universally	Achieves flood risk mitigation by adjusting permitted land use	Low but may incur private property rights conflicts and litigation	Private property rights conflicts and litigation
Gray	Roadway base protection	Low-lying areas, coastal communities	Protects roads and access routes	$1 million per lane-mile	Cost, adjacent properties become uninsurable
Policy	Enhanced elevation of buildings	Developers would implement this for new construction	Reduced flood risk	Varies	Potential issues with building structure or latticework, and existing homes that are not elevated

2.5.3 Impacted Adjustment Areas

In the evaluation of flood risk management strategies within the framework of the National Flood Insurance Program Community Rating System (CRS), the concept of impact adjustment plays a pivotal role in determining the extent to which CRS-credited activities or elements influence the vulnerability of a community's Special Flood Hazard Area (SFHA) and the structures located within it. It is important to note that while the usual results of impact adjustment are related to the SFHA area, in this specific analysis, it was used 1-day 100-year storm event inundation area performed by FAU instead.

In this context, the following table presents a breakdown of the impact adjustment calculations for a 1-day 100-year storm event inundation. The values are expressed in acres and depict the areas of interest as well as the deductions considered in the evaluation process.

The outcomes of these calculations provide valuable insights into the impact adjustment scenarios:

With ALL State Lands:

This scenario reflects the remaining inundation area after accounting for deductions A, B, and C. It represents the effect of CRS-credited activities without considering the influence of state lands in managing flood risks.

With NO State Lands:

In this case, the remaining inundation area is determined by considering all deductions, including state lands (both open space and not open space– see **Error! Reference source not found.**).

These calculations highlight the dynamic nature of impact adjustment within the CRS framework. By accurately gauging the influence of individual elements, the system ensures that credit allocations align closely with a community's efforts in flood risk mitigation.

Table 11. Impacted Adjustment Areas for HUC 031402031102. Processed by FAU.

AREAS	**ACRES**
HUC-12 Sub-watershed: 031402031102	28288.77
All of the 1-day 100-year storm event inundation	**9114.77**
Subtract	
A. Bodies of Water in 1-day 100-year inundation > 10 acres	8256.64
B. Federal Land in 1-day 100-year inundation > 10 acres	0.00
C. Reservation/Tribal Land in 1-day 100-year inundation > 10 acres	0
D. State Land in 1-day 100-year inundation > 10 acres that is open space	636.99
E. State Land in 1-day 100-year inundation > 10 acres that is NOT open space	1.75
The remainder is either:	
With ALL State Lands: All of the 1-day 100-year inundation minus (A+B+C) or	858.13
With NO State Lands: All of the 1-day 100-year inundation minus (A+B+C+D+E)	219.39

2.5.4 Repetitive Loss Property Map

A Repetitive Loss (RL) property is a building that has had two or more loss or damage due to a specific hazard, such as floods, hurricanes, or other natural disasters, over $1,000 each, paid by the National Flood Insurance Program (NFIP) within any ten-year period since 1978. There are more than 122,000 RL properties in the nationwide (FEMA, 2005).

These data are essential for assessing the vulnerability of certain areas to recurrent losses and for developing strategies to mitigate the risks. However, due to privacy concerns, the data cannot be openly shared with the public. For this reason, the data were converted into a hot spot analysis map. These maps, instead of identifying the specific location of the repetitive loss properties, highlight clusters of repetitive loss claims and areas where the probability of repetitive losses is higher than would be expected by random chance. In other words, it helps pinpoint locations that have a higher concentration of properties prone to repetitive losses. **Error! Reference source not found.** indicates the results from hot spot analysis in point data, showing aggregated counts, and raster data, showing the estimated probability of repetitive loss.

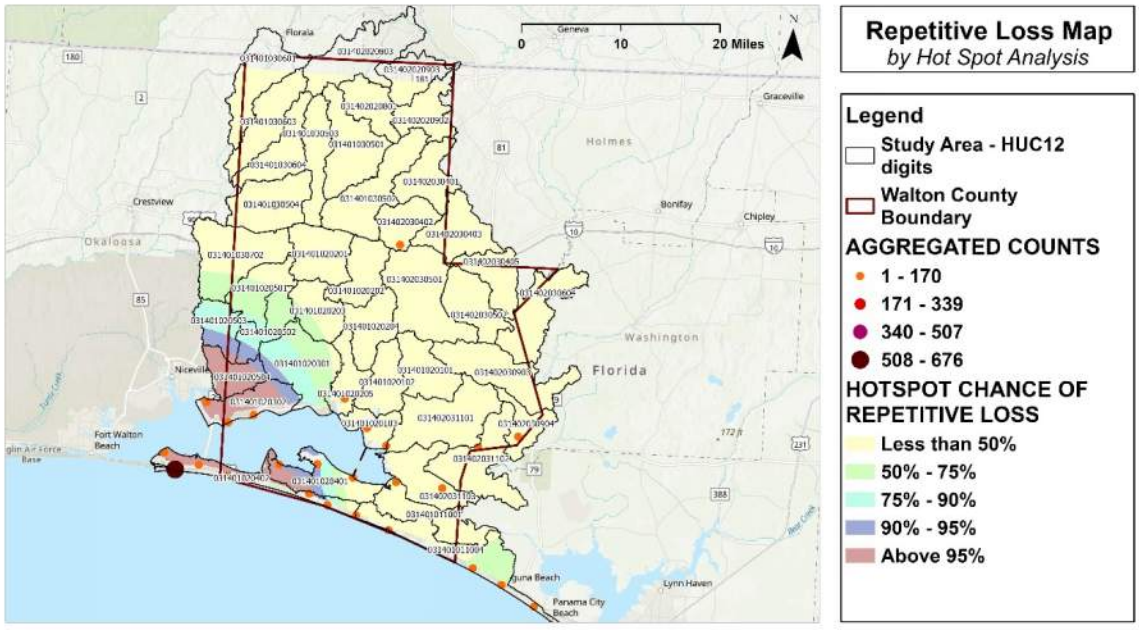

Figure 66. Repetitive Loss map for Walton County by Hot Spot Analysis. Processed by FAU. (Source Data: FEMA)

2.5.5 Priority Projects

While the basin does not have a significant amount of developed land, some parcels fall within the flood zone due to the area's susceptibility to significant flooding in both 1-day 100-year storm

events and 1-day 100-year + 5 feet sea level rise scenarios. In terms of land use priority, there are some parcels in tiers 2 (roads), 4, and 5 within the flooding zone. There is only one Tier 1 priority parcels, that fortunately is not in the flooding zone.

Examining the composite score, there are a total of 38 parcels within the flood zone that require attention. Among them, five are in the score range of 5-6, all of which are roads (Smokehouse Run, East Pocket, Smokehouse Run, Buzzards Roost, and River Shannon), representing the highest priority for intervention. Additionally, there are 13 parcels, which 5 of them are mobile homes, and 8 are also roads (B H Reddick Rd, Us Hwy 20, Choctawhatchee River Rd, Cowford Rd, Co Highway 3280, Smokehouse Lake Road, Herring Rd, and one more with no name), with scores in the range of 3-4. Finally, there are 20 parcels with scores below 3, all of which are mobile homes.

X.0 EXECUTIVE SUMMARY

The goal of the appendices to the watershed plan are to outline the issues associated with the individual HUC12s that contribute or impact the community's flood vulnerability and there for its flood protection efforts. Floodplain analysis includes developing a watershed model and identifying associated inundation polygons. It builds upon information generated from the watershed evaluation so that planning and management decisions can be formulated.

This appendix describes the issues and modeling associated with one of the HUC12s that affects Walton County. In developing the County-wide plan, this HUC 12 was analyzed so as to determine how it brings or removes floodwaters from the County. For the NFIP process the goal is to analyze all communities at the HUC12 level. From a community perspective the HUC12 is less useful to residents than a community-wide plan. Hence in all cases the HUC12 results were mosaicked into the community-wide plan. Details can be found in the HUC12 appendices, some of which were brought into the community plan.

To reduce redundancy, information of the plans, ordinances, policies and regulations were rolled up to the community-wide plan and will not be repeated in the appendices. Likewise, the community wide mapping was parced for HUC12 use.

1.0 WATERSHED CHARACTERIZATION

In this section, key aspects of the watershed are characterized. This is important for later being able to identify the most vulnerable areas and to mobilize resources to implement an action plan. Understanding the characteristics of the watershed involves gathering existing information and data sets from previous planning efforts. It is important to note that this step is iterative and ongoing as new data are generated and projects are implemented and monitored.

To assess the historical and current conditions of the study area, the following existing data sets that characterize the physical and natural features of the watershed were obtained for each HUC-12 subwatershed in the study area:

- Topographic data (LiDAR)
- Relevant waterway locations
- Groundwater levels
- Soils data
- Land uses including vacant land, wetlands, impervious, etc.
- Precipitation records
- Catchment delineations for flood routing

In addition, the FEMA flood maps must be obtained, and the storm of interest must be identified for screening purposes (1-day, 2-year, 5-year, and 100-year events as well as the 3-day 25-year storm event to achieve class 4 in the CRS Manual). In developed areas, many sources of data are already available – the key is putting the key datasets in a format that can queried for screening to identify the priority areas of the watershed. Table 6 is a summary of datasets available at cwr3.fau.edu that were used to construct this plan.

This watershed master plan is a drilldown of the larger Walton County TMDL region, which involves 42 HUC 12-digit sub-(watersheds (**Error! Reference source not found.**). **Error! Reference source not found.** shows Walton County Drainage Network and the location of urban areas (cities and towns). In **Error! Reference source not found.**, the HUC-12 (031402031103) is highlighted among all the HUCs to help identifying its location (Figure3).

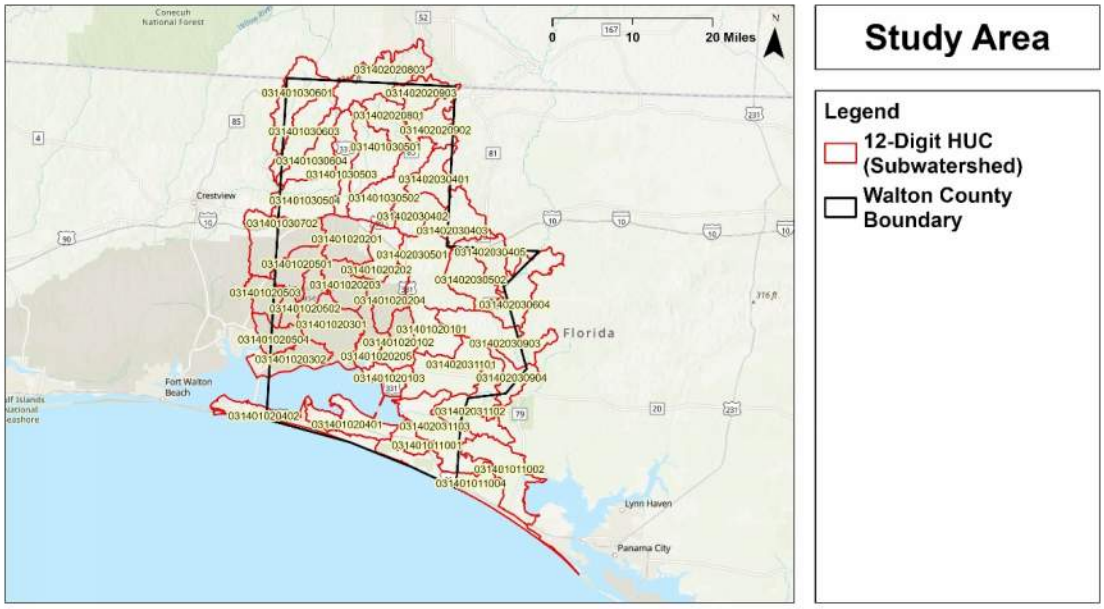

Figure 1. Walton County and all HUCs 12-digit subwatershed, processed by FAU.

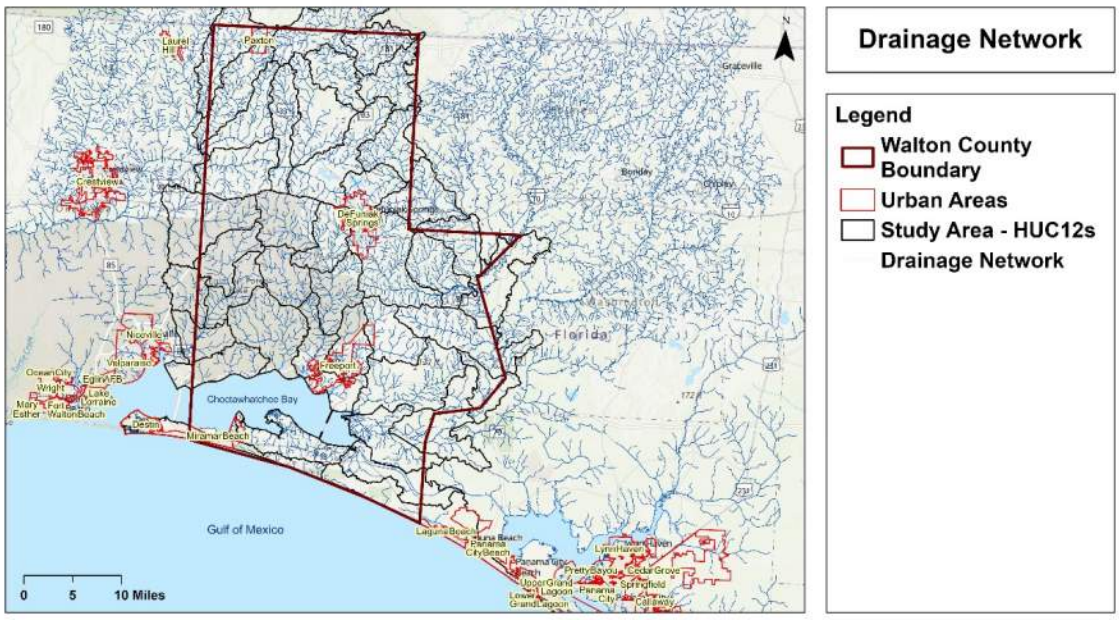

Figure 2. Walton County Drainage Network and urban areas (cities and towns), processed by FAU.

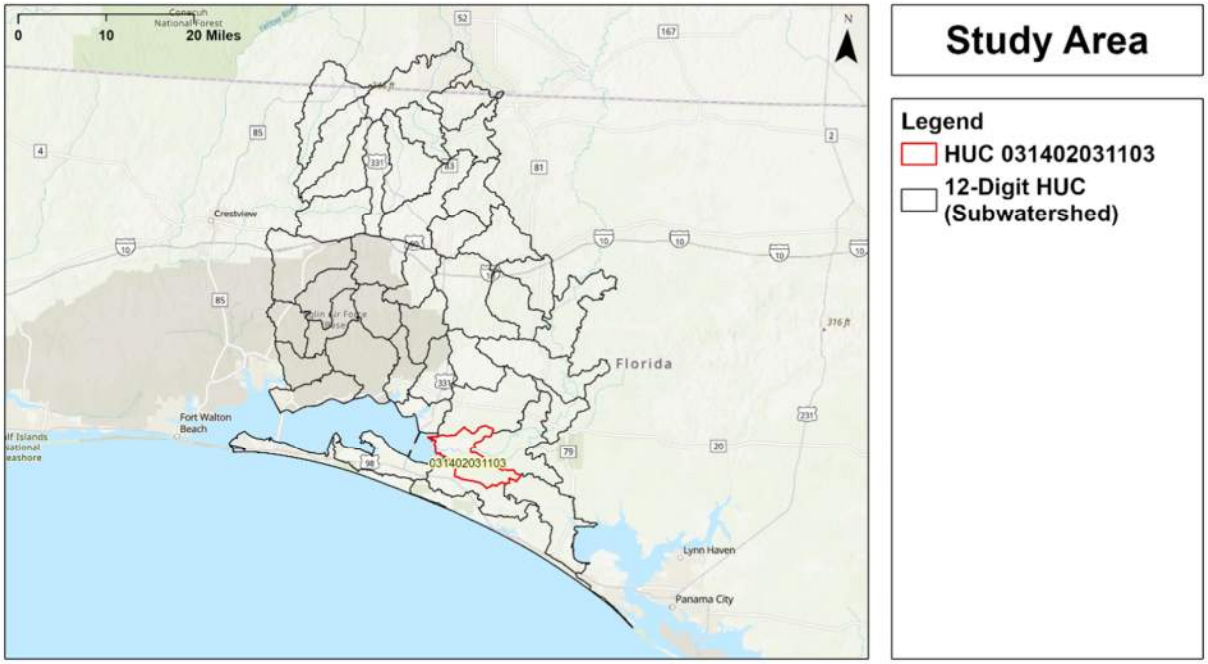

Figure 3. HUC 031402031103 sub-watershed location.

Located in the northwestern region of Florida, Walton County has 1,037.7 square miles of land and it is the 12th largest county in Florida by area, while also sits the highest point in the state,

with a height of 345 feet in its northern end. With a population of 75,305 residents according to the 2020 census and an estimate population in July of 2022 of 83,304, the county has experienced consistent growth within the past several years, driven by factors such as tourism, retirement migration, and regional population dynamics. The county was the residence for 55,043 people according to Census 2010, which leads to a percent change of 36.8% in 10 years, between 2010 and 2020, and a percentage change of 10.6% in two years, between 2020 and 2022 (United States Census Bureau).

The surge in population, particularly in the southern part of Walton County, has resulted in a corresponding expansion of infrastructure to cater to the growing needs. Essential facilities such as potable water systems, wastewater treatment plants, electrical utilities, roads, and schools have been developed to support this increasing population. However, the infrastructure expansion has brought about a significant change in the natural environment. Prior to the existing development , tropical cyclone impacts would be mitigated by natural barriers such as vegetated sand dunes, wetlands, and deserted beaches, which would absorb some of the destructive forces. Now, with the proliferation of costly infrastructure and residential dwellings in coastal areas, these storms pose a higher risk of potential damage. The very areas where development is occurring are becoming more vulnerable to the impact of severe storms, highlighting the importance of considering and implementing adequate measures to address potential storm damage in these coastal regions (Walton County Local Mitigation Strategy Plan, 2015).

Demographically, Walton County presents a heterogeneous age distribution, encompassing a blend of younger and elderly cohorts. The median age of approximately 44 years reflects the presence of both younger families and retirees seeking a serene and picturesque environment. Ethnically, the county' population is predominantly White with smaller yet notable populations of Hispanic/Latino, African American, and other racial/ ethnic groups.

Economically, the tourism sector stands as a dominant force in Walton County, constituting 23.4 percent of the workforce, according to Walton County Economic Development Alliance in 2011, due to its renowned beach destinations, such as Santa Rosa Beach, Miramar Beach, and the New Urbanist Communities of Seaside and Rosemary Beach. Following closely behind is the trade, transportation & utilities sector, accounting for 20.3 percent of employment, while construction stands at 10.0 percent in third place. Education, health care services, and public administration also play significant roles within the top five employment sectors, reflecting the diversified economic landscape of the county (Walton County Local Mitigation Strategy Plan, 2015).

The natural environment in Walton County contributes to its distinctive appeal to visitors and tourists. The county's coastal environment along the Gulf of Mexico showcases picturesque vistas, including white sand beaches, undulating dunes, and coastal dune lakes. These lakes, a rarity worldwide, provide unique ecological habitats. Walton County is also committed to environmental conservation, with designated protected areas comprising state parks, forests, and wildlife

management zones. These preserved landscapes offer abundant opportunities for recreational activities, including hiking, fishing, and birdwatching.

The presence of wetlands and waterways further enhances the natural attributes of Walton County. Various rivers and creeks alongside Choctawhatchee Bay permeate the landscape, fostering diverse ecosystems and serving as crucial habitats for a wide range of wildlife species. This rich natural heritage encourages exploration and nurtures an appreciation for the environment.

DeFuniak Springs serves as the county seat and boasts a diverse economy. Anchored by sectors such as healthcare, education, retail, government services, and a thriving small business community, DeFuniak Springs offers a range of employment opportunities. Surrounded by the natural beauty of forests, lakes, and wetlands, the city enjoys the presence of Lake DeFuniak, a noteworthy natural resource. With a population of approximately 5,100 residents, DeFuniak Springs is a vibrant city featuring a mix of economic activities. The land area of DeFuniak Springs is approximately 12.6 square miles (32.7 square kilometers).

Freeport boasts a diverse demographic profile, and a developing economy. The city is situated along the shores of Choctawhatchee Bay, which provides opportunities for recreational opportunities and supports local ecosystems. Surrounded by lush forests and intersected by waterways, Freeport enjoys a rich environmental setting. In terms of economics, Freeport's economy is in a phase of growth and diversification, with sectors including healthcare, education, retail, and small businesses. The city is also strategically positioned for future economic expansion due to its proximity to major transportation corridors. Demographically, Freeport is a close-knit community with a population of approximately 2,600 residents, comprising a mix of permanent residents, retirees, and individuals seeking a suburban or rural lifestyle. The city reflects a diverse demographic composition, showcasing a variety of cultures, and backgrounds. Freeport occupies a land area of about 13.6 square miles (35.3 square kilometers).

Further along the coast, Miramar Beach stands as a coastal gem known for its tourism and hospitality industry. Luxury resorts, vacation rentals, gourmet restaurants, high-end retail shops, and entertainment venues thrive within this bustling city. Miramar Beach's main attraction lies in its stunning white sand beaches along the Gulf of Mexico, providing endless opportunities for beach activities and water sports. Its boundaries extend into neighboring Okaloosa County, attracting a blend of permanent residents, vacation homeowners, and rental property occupants. Miramar Beach, including its neighboring areas, covers an estimated land area of around 4.7 square miles (12.2 square kilometers).

Continuing along the Gulf Coast, we encounter Santa Rosa Beach. This coastal community is renowned for its vibrant tourism industry, offering a plethora of accommodations ranging from upscale resorts to charming vacation rentals. Its demography reflects a mix of permanent residents, seasonal visitors, and individuals seeking a coastal lifestyle, resulting in a diverse and dynamic

community. Santa Rosa Beach spans a larger area compared to other cities in Walton County, with an estimated land area of approximately 31.2 square miles (80.8 square kilometers).

A summary of the existing CRS classifications for the communities in the study area is listed in **Error! Reference source not found.**. No cities in Walton County are listed in the FEMA Community Rating System Eligible Communities.

Table 1: Community Rating System for Walton County. Effective April 1, 2023.

Community #	**Community Name**	**CRS Class Rating**	**Premium Discount for SFHA**	**% Discount for Non- SFHA**	**Status**
120317	Walton County	6	20%	10	Cycle

(Source Data: FEMA)

Figures 12 and 13 is the county-wide report show the current and projected land use for the County. Based on the 2017 future land use for Walton County, only 7.07% of the land use in the county is urban and built up, and water/wetlands makes up 29.16% of the land use. The majority of land is upland forest, with 48.3%, as shown in **Error! Reference source not found.**

Table 2. Land Use in Walton County (Prepared by FAU from future land use map) versus land use in the entire watershed

Level 1 Land Use-Land Cover Type	**Area (Acres)**	**Percentage of Total**
Agriculture	52958.94669	7.17%
Barren Land	9242.05986	1.25%
Rangeland	40326.66002	5.46%
Transportation, Communication, and Utilities	11815.69287	1.60%
Upland Forest	356796.0541	48.30%
Urban and Built-Up	52194.79061	7.07%
Water	61593.80508	8.34%
Wetlands	153759.9055	20.82%
Total	**738687.9147**	**100.00%**

(Source Data: (NWFWMD 2017)

Walton County has a history of flooding and has implemented various measures for flooding mitigation over the years (see section 1.12 for more details). The County has experienced flooding primarily due to heavy rainfall events and proximity to large water bodies such as the Gulf of Mexico, Choctawhatchee Bay, and numerous rivers and creeks. The topography of the region, with low-lying areas in the coastal areas and wetlands, also contributes to flood vulnerability. The

proximity to the ocean (Gulf of Mexico) makes the county vulnerable to sea level rise. Over the years, Walton County has faced multiple flooding incidents, including:

- March 1997: Heavy rainfall led to significant flooding throughout the county, resulting in property damage and road closures.
- April 2009: Intense storms caused widespread flooding, damaging homes and infrastructure and resulting in the declaration of a state of emergency.
- April 2014: Heavy rainfall caused severe flooding, leading to the evacuation of some residents and the closure of roads.

Today,, the goal of a stormwater management system in many communities is to keep the community as a place to live and do business while limiting risk from damage due to flooding. The short-term impacts from stormwater include flooding in low-lying areas and standing water in areas with limited soil storage capacity. Less common, but of increasing frequency, is the potential for extensive inundation of some areas, especially low-lying areas, during periods with high groundwater levels and groundwater impacted by sea level rise. As a result, there is a need to understand the economic impact of flooding events and to create cost-effective stormwater infrastructure and policy solutions to protect property. This means preserving as much property and economic activity as possible without disrupting current activity or expending funds on inappropriate projects with limited long-term or social value.

1.1 Surface Topography

Topography is a key parameter that influences many of the processes involved in flood risk assessment, and thus, up-to-date, high-resolution, high-accuracy elevation data are required. In order to meet the requirements for FEMA Risk Mapping, Assessment, and Planning (RiskMAP), 1-meter (2015 to present) and 1/9 arc-second (~ 3-meter) (2010 -2015) LiDAR DEMs were acquired. The 1 m × 1 m LiDAR tiles were kriged to create a topographic map of the study area (Figure4). This accuracy meets the 3DEP Quality Level 2 vertical root mean square error accuracy threshold of ±10 cm for FEMA (Arundel et al., 2015). The LiDAR used for this basin was 2016.

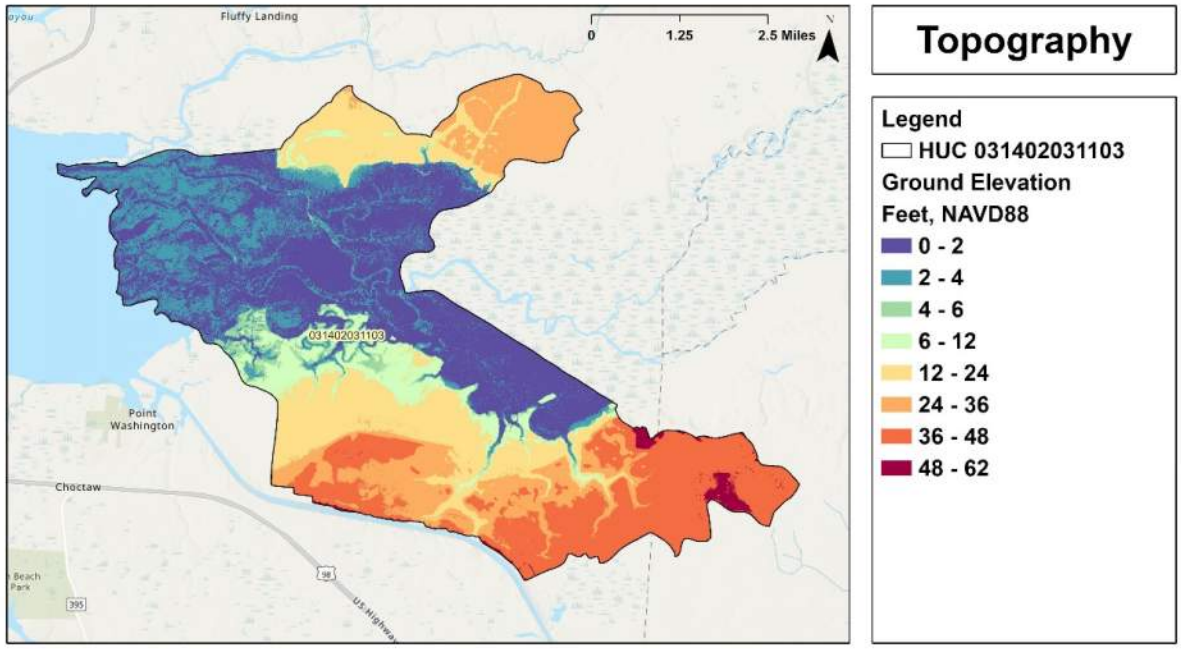

Figure 4. Topographic map of the HUC 031402031103 sub-watershed, processed by FAU. (Data Source: USGS)

1.1.1 Geomorphological Considerations

Walton County's coastal area is characterized by the presence of barrier islands, extensive sandy beaches, and coastal dune systems. These features are influenced by the dynamic processes of wave action, tidal currents, and wind-driven sediment transport. The shoreline is subject to natural changes, including erosion and accretion, which significantly shape the coastal geomorphology.

Inland Walton County exhibits a mix of wetlands, forests, rolling hills, and rivers. These landforms are influenced by a combination of factors, including underlying geology, fluvial processes, and the region's hydrological regime.

Like many areas in Florida, Walton County is underlain by limestone formations. The specific composition and properties of these limestone formations in Walton County may vary. However, limestone is generally known for its porous nature, which allows for the absorption and storage of water. Underground aquifers within the limestone formations can hold significant volumes of freshwater, contributing to the region's water resources.

For context, the FIRM panel index of HUC 031402031103 sub-watershed is shown in Figure5.

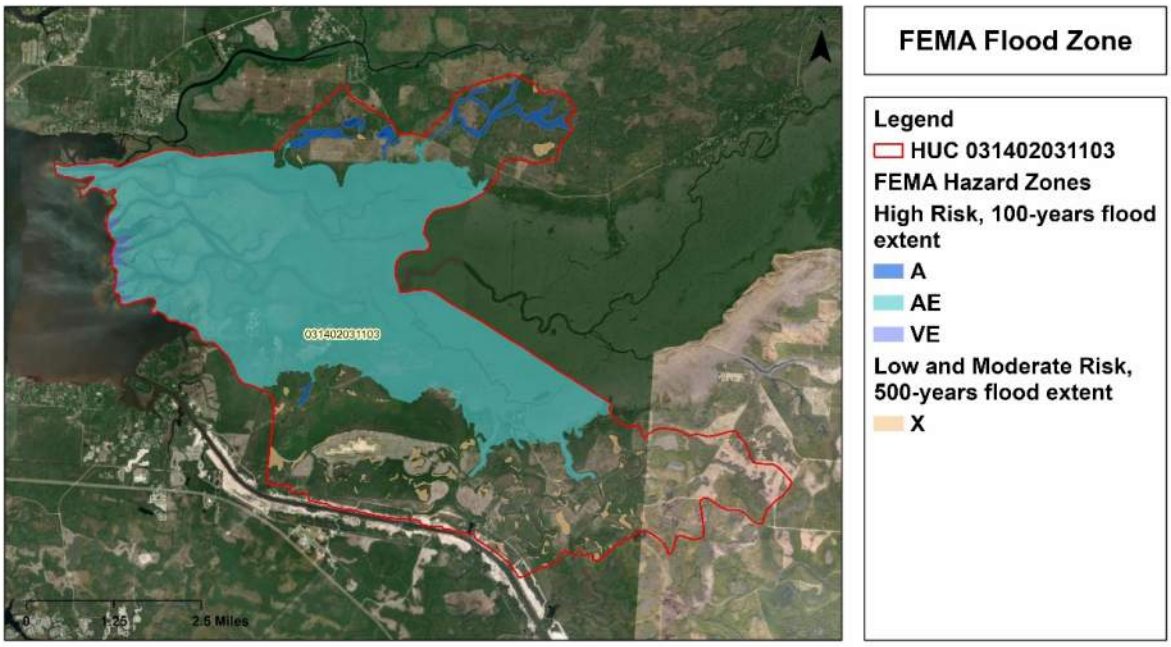

Figure 5. FEMA Flood Zone map (2020) for HUC 031402031103 sub-watershed, processed by FAU.
(Data Source: FEMA)

1.1.2 Waterway Features

In Walton County, Florida, the waterway features are primarily influenced by the presence of rivers, creeks, bayous, and the proximity to the Gulf of Mexico. To the south of Walton County lies the Gulf of Mexico. Sandy beaches, barrier islands, and the open waters of the Gulf itself characterize the coastline along the Gulf. The Gulf of Mexico influences the coastal processes, including wave action, tidal currents, and sediment transport along the shoreline. The combination between sea level rise and King tide would have detrimental consequences for the county costal area, including the sub-watershed 031402031103 as it will reach the area thought Choctawhatchee Bay.

Walton County is home to several rivers and creeks that meander through its landscape. These waterways provide drainage for the inland areas and contribute to the overall hydrological system. Examples of significant rivers in the county include the Choctawhatchee River and the Shoal River. In addition, Walton County features bayous and estuaries that connect inland water systems to the Gulf of Mexico.

Choctawhatchee Bay serves as a vital estuarine ecosystem, where freshwater from rivers and creeks mixes with the saltwater from the Gulf of Mexico, serving as a vital estuarine ecosystem. This unique brackish water environment supports a rich diversity of flora and fauna, including various fish species, shellfish, migratory birds, and wetland vegetation, contributing to the overall biodiversity of the region. It also plays a significant role in the local economy of Walton County as it supports commercial and recreational fishing industries, providing livelihoods for local fishermen and contributing to the seafood industry, while also offering a range of recreational opportunities for residents and visitors alike, such as boating, kayaking, paddle boarding, and sailing. **Error! Reference source not found.** shows the bathymetry offshore.

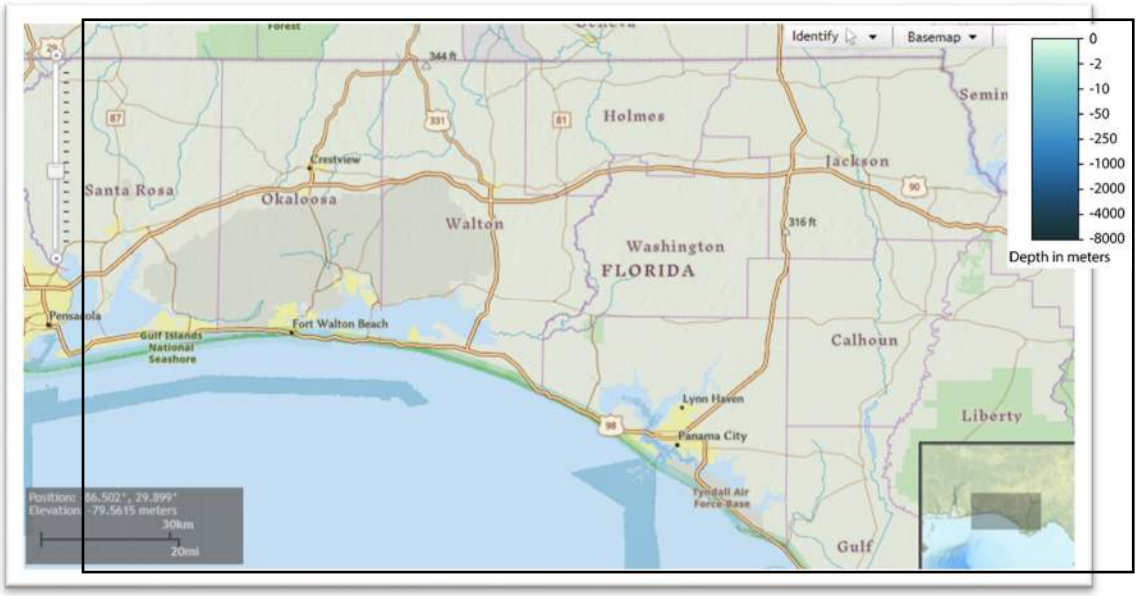

Figure 6. Bathymetry map of the shore of Walton County and surrounding counties of Florida Panhandle.
(Source: ncei.noaa.gov/maps/bathymetry/)

Numerous tributaries exist throughout both the freshwater and estuarine portions of the watershed and can influence the overall hydrology of the area depending on rainfall and regional hydrological conditions. **Error! Reference source not found.** shows the location of all four surface water stations along with ground water stations (wells) and the drainage network of Walton County.

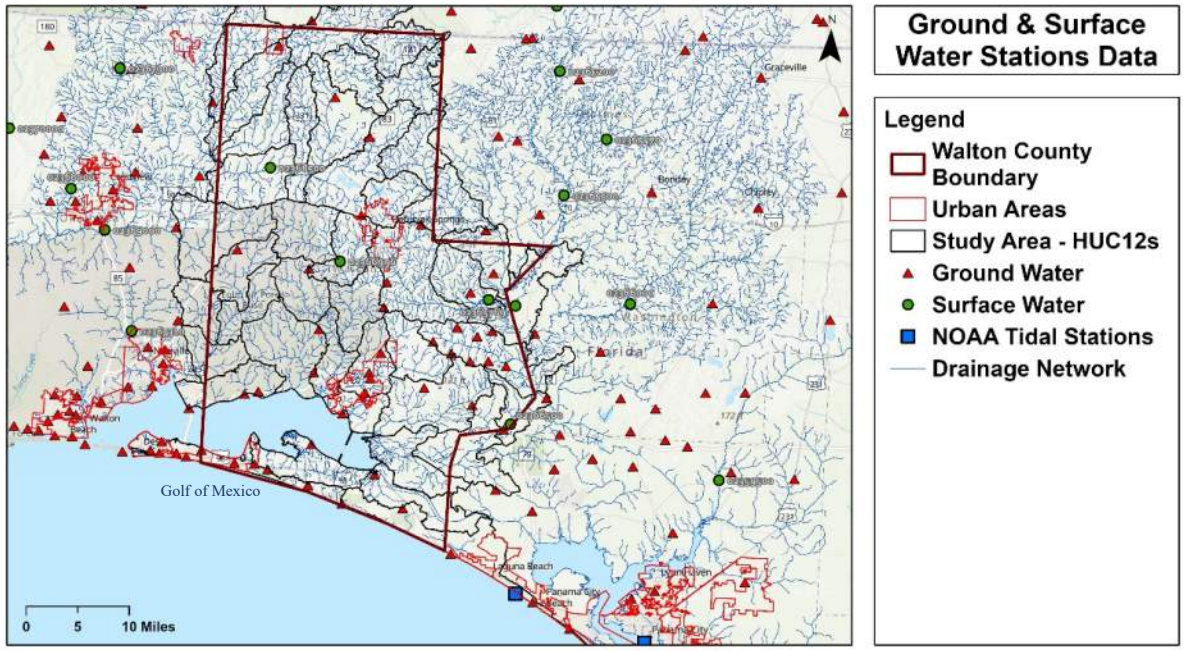

Figure 7. Ground & Surface Water Stations with drainage network for Walton County, processed by FAU.
(Data Source: USEPA – National Hydrographic Dataset (NHD) and NOAA's Tides)

1.1.3 Hydrologic Boundaries

The geographic area of the subject sub-watershed should be clearly defined to ensure that implementing the WMP will address all the major sources and causes of impairments and threats. Although there is no rigorous definition or delineation of this concept, one way to identify the geographic extent of the watershed master planning effort is to consult the United States Geological Survey (USGS) map of hydrologic units. A hydrologic unit is part of a watershed mapping classification system showing various areas of land that contribute surface water runoff to designated outlet points, such as lakes or stream segments. USGS designates drainage areas as sub-watersheds (including smaller drainages) numbered with 12-digit hydrologic unit codes (HUCs), nested within watersheds (10-digit HUCs). These are combined into larger drainage areas called subbasins (8 digits), basins (6 digits), and subregions (4 digits), which make up the large regional drainage basins (2 digits).

Region>>Subregion>>Basin>>Sub-basin>>Watershed>>Sub-watershed

The major water bodies in the sub-watershed are the Choctawhatchee Bay at the west side of the HUC-12 with the associated rivers and canals:

- Choctawhatchee River
- Mitchell River
- Indian River
- Cypress River
- Williams Lake
- Sister River
- Reedy Branch
- Tenmile Branch
- Ninemile Branch
- Roaring Creek

Given that stream flow data are critical for estimating flooding, **Error! Reference source not found.** shows the historical streamflow during June 2022 to July 2023 for USGS 02366500. However, as there are only four surface water station within Walton County, it was necessary to use the nearest station to the sub-watershed 031402031103, which is USGS 02366500 Choctawhatchee River NR Bruce FLA.

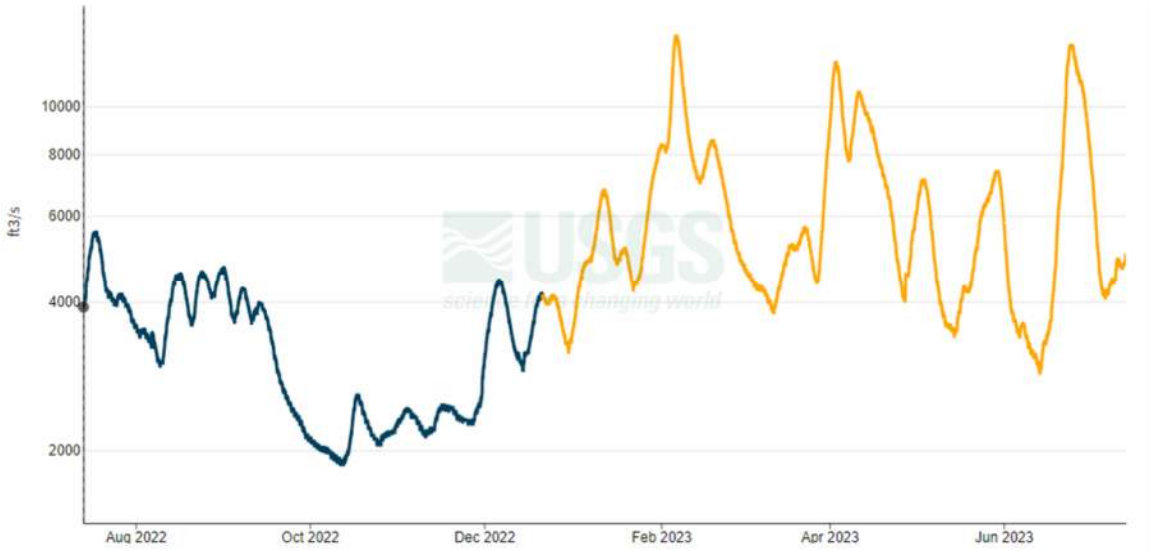

Figure 8. Average streamflow for Choctawhatchee River NR Bruce FLA (USGS 02366500 Surface-Water, June 2022 to July 2023).
(Source: USGS Water Data Services, available at https://waterdata.usgs.gov/monitoring-location/02366500/#parameterCode=00065&period=P365D)

1.2 Groundwater

In this region of Florida, there is a direct interaction between groundwater and surface water. In addition to low land elevations and topographic relief, the groundwater and surface water are controlled by the canals, rivers, and tides. Since there is a limited number of groundwater monitoring stations, the strong relationship between groundwater and surface water was leveraged to develop a 99^{th}- percentile surface of the water table elevation for mapping purposes. To establish a common date for modeling, the recorded groundwater table elevations were sorted in ascending order to determine the 98^{th} - 100^{th} percentile date of occurrence in Excel®, following the procedure detailed in Romah (2011). This procedure was automated for this effort using a python code to process the groundwater data more efficiently. Outliers and anomalous groundwater levels in the database are initially identified (e.g. catastrophic storm events) and replaced by region-specific mean values based on observations available from the nearest well. Missing date-specific data are estimated using simple temporal interpolation based on observations available in time. If a station (or monitoring well) data contains large amounts of missing data, it is not used in the generation of the groundwater surface.

In Walton County, the average annual rainfall is abundant, reaching 65 inches at DeFuniak Springs. This rainfall predominantly infiltrates the sand-and-gravel aquifer and eventually seeps into streams or the underlying artesian Floridan aquifer. The county's two major aquifers are the sand-and-gravel aquifer and the Floridan aquifer. While the sand-and-gravel aquifer provides water for rural domestic use and plays a crucial role in water storage and streamflow maintenance, it also serves as a recharge source for the Floridan aquifer. Water from the sand-and-gravel aquifer contains varying levels of dissolved solids, pH, and iron content. The Floridan aquifer, being the primary water supply source, underlies the entire county and yields around 500 to 1,000 gallons per minute from wells, except along the Gulf Coast where the permeability is lower. Recharged by leakage from the sand-and-gravel aquifer, the Floridan aquifer's movement is predominantly southward away from the potentiometric high in northwestern Walton County. It discharges through springs, seeps along the Choctawhatchee River, and by wells. In southern Alabama, the Floridan aquifer is directly recharged by rainfall when it is exposed or close to the land surface. (Bureau of Ecology, 1974).

Once a common time period is determined across the majority of shallow groundwater wells, canal data can be gathered for that common date (and two days prior, in the event the canals were deliberately lowered). Data was obtained from the NWFWMD and processed by FAU at cwr3.fau.edu. Between stations, an ArcGIS tool permits a line to be drawn to replicate the canals and establish points in a gradient between stations. The same is true for the ocean, but it is a constant head boundary. The canals form boundary conditions for the screening tool on the edges of the basin and affect localized groundwater. The tide issue is resolved by using the common date for high tide.

Error! Reference source not found. shows the drainage network of HUC 031402031103 and points out the location of the only one ground water station in the surroundings. A groundwater-surface layer for the HUC 031402031103 sub-watershed was created using several datasets including water level data from USGS and NWFWMD and groundwater elevation contour maps. The datasets were used to generate a raster surface of the groundwater elevation (**Error! Reference source not found.**).

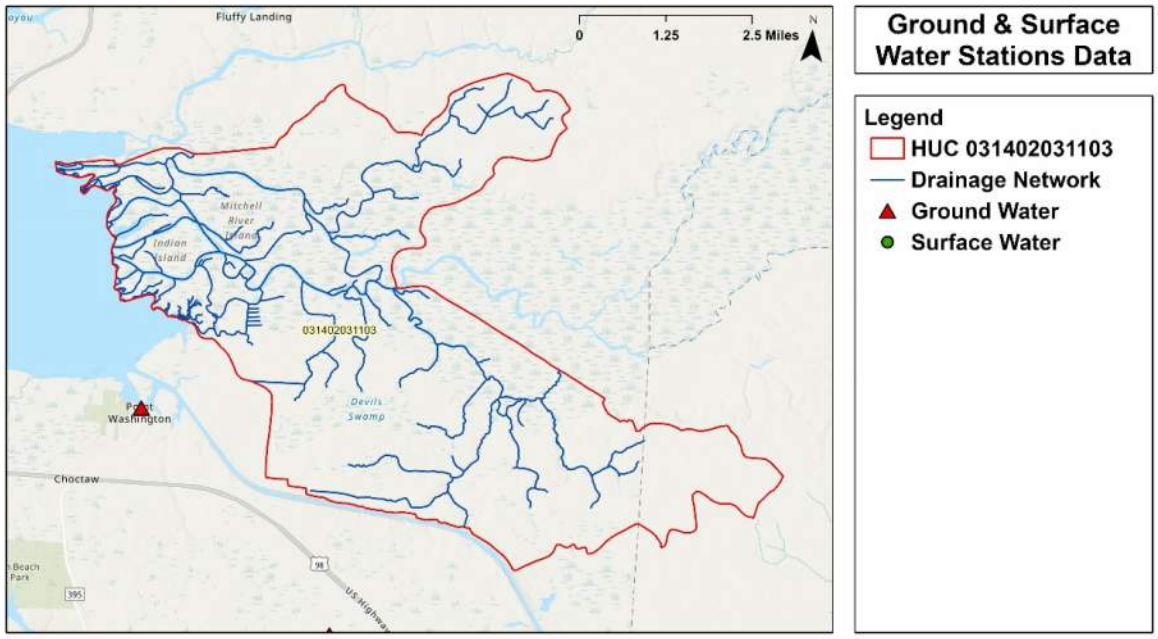

Figure 9. Ground and Surface Water Stations in the HUC 031402031103 sub-watershed, processed by FAU.

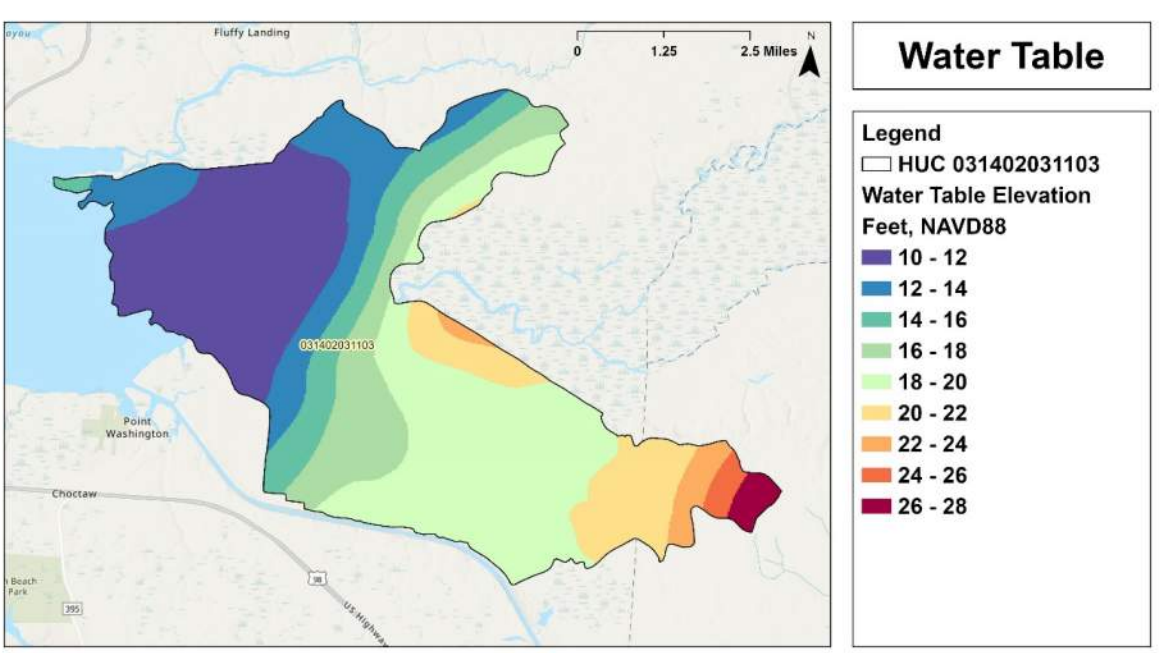

Figure 10. Elevation of the top of the surface groundwater layer for the HUC 031402031103. Created by multiple linear regression analysis – elevation NAVD88, processed by FAU. (Data Source: USGS and NWFWMD)

1.3 Surface Water/Tides

Historically, surface water and tides have been an important factor in determining how much freshwater is delivered, how fast this water enters wetlands and estuaries, and the quality of that water. Evapotranspiration and rainfall do not coincide in the study area, which makes water supply planning difficult. **Error! Reference source not found.** shows the average precipitation over Walton County for every month of the year between 2011 and 2023 - each rectangle is a month and each column is a year. The 12-month total precipitation decreased 7.5 inches from May 1900 to April 2023. From May 1900 to April 2023, the average 12-month total precipitation was 60.5 inches for the entire county.

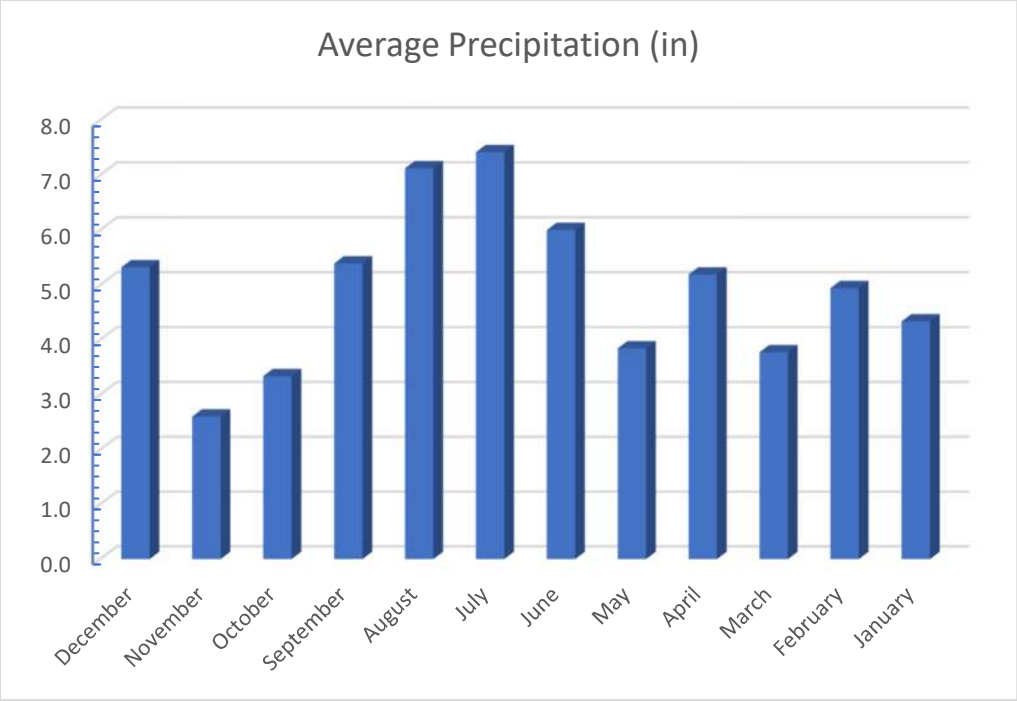

Figure 11. Monthly precipitation in Walton County, FL (2011-2023).
(Data Source: Florida Weather Data, available at https://data.usatoday.com/weather-data/walton-county/12131/1975-04-01/table/)

While the topography (Section 1.1) and native soil (Section 1.4) create an environment that is highly permeable and capable of infiltrating significant percolation into the soil, changes in land use and land cover have resulted in water falling on impervious areas, where the water collects in pools or runs off rapidly, in direct contrast to the natural condition. This runoff flowing over impermeable regions can lead to larger scale flooding.

Tidal data can be gathered from NOAA tidal gages and other gages monitored by local governments. The location of tide gages is important to ensure they accurately depict tides, as opposed to inland waters. To set a boundary for the coastal areas, the high tide on the common date from 12/03/2018 to 12/10/2018 was selected. **Error! Reference source not found.** shows the two closest tide stations to Walton County. Since there is none NOAA tide station in Walton County, the Panama City Beach station (8729210) was used.

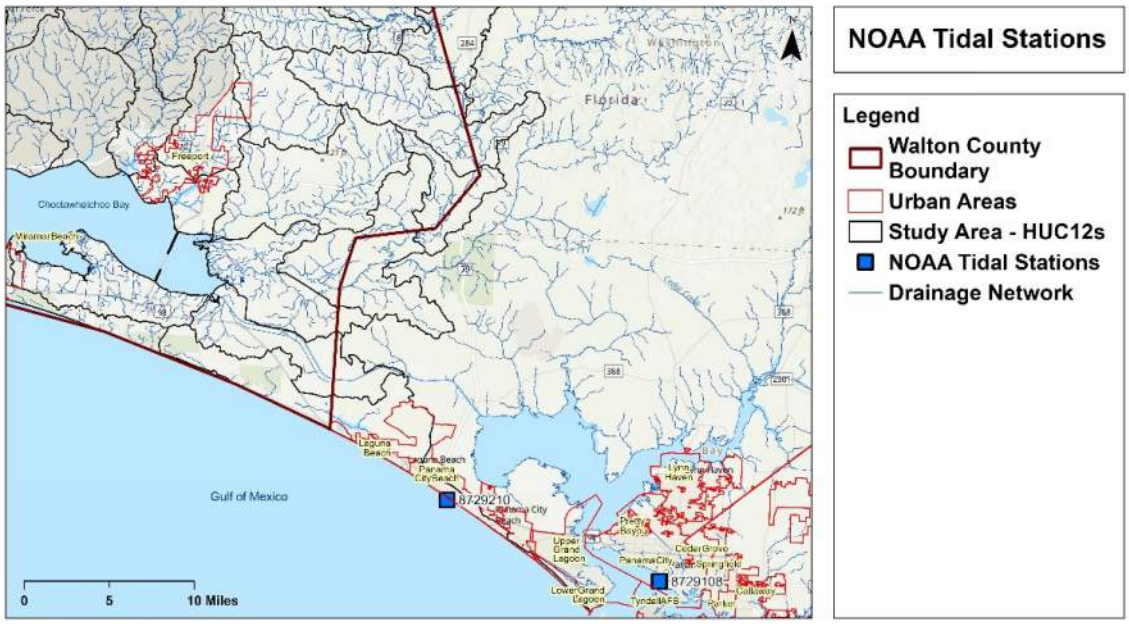

Figure 12. Locations of Florida tidal stations maintained by NOAA near to Walton County, processed by FAU.
(Data Source: USEPA – National Hydrographic Dataset (NHD) and NOAA's Tides)

1.4 Soils

Soil can store water if there is adequate distance between the topographic surface and the groundwater, and the soil types are capable of absorbing the water. Soil storage capacity is the volume of soil pores in the unsaturated zone that is available to store infiltrated stormwater (Gregory et al., 1998). Throughout Florida, it is common to have large volume storm events that fill the voids in the unsaturated zone as shown in Figure 13.

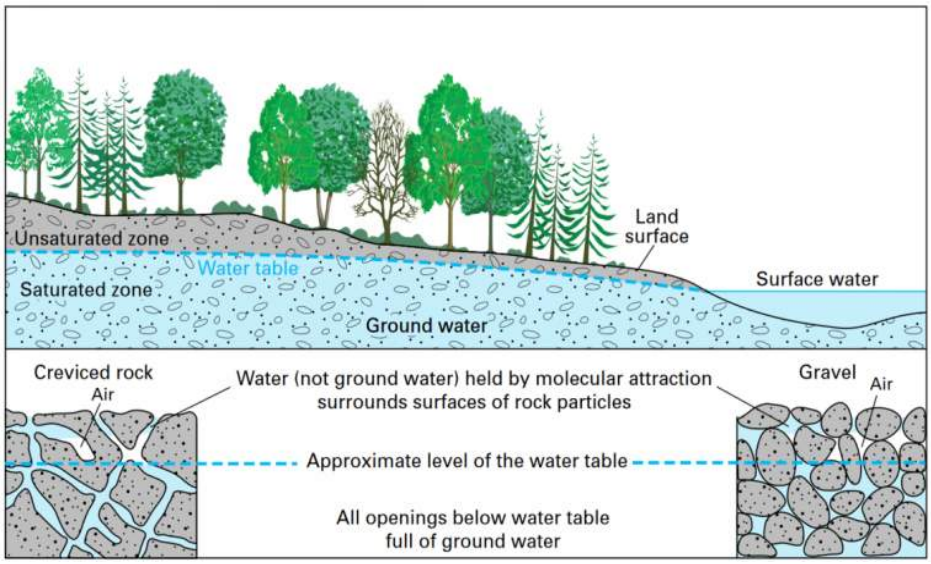

Figure 13. Zones where underground water exists.
(Source: USGS, 2020)

The unsaturated zone is the portion of the subsurface above the water table that contains soil/rock and air and water in its pores as shown in Figure 14. This zone affects the rate at which the aquifer is recharged by controlling water movement from the surface of the land downward towards the aquifer. During rain events, the soil voids fill up quickly resulting in the water table rising to the surface, and the surplus rainfall becomes runoff.

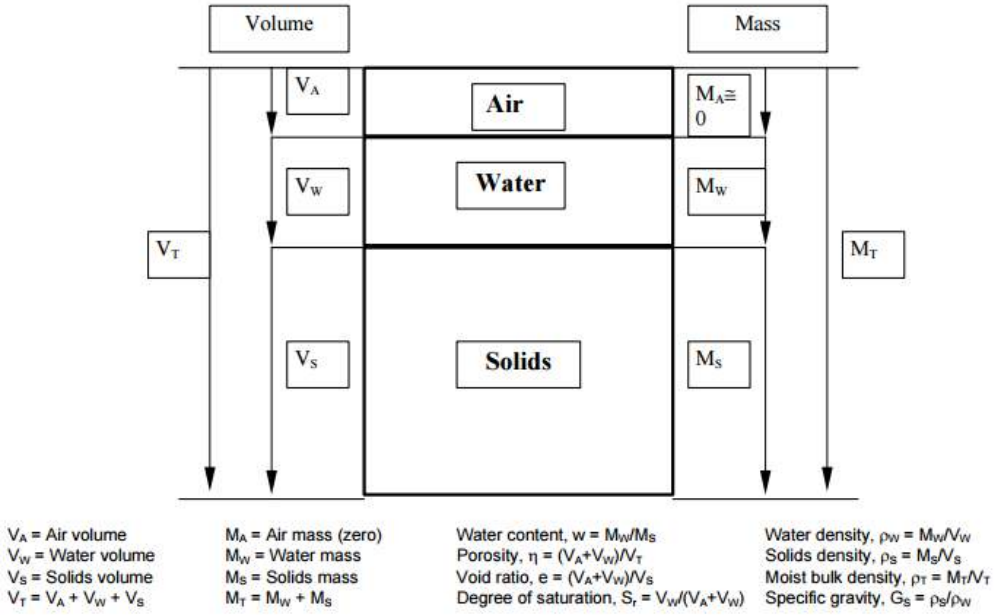

Figure 14. Saturated zone soil phase diagram and definitions.
(Source:Gregory et al., 1998)

Soil data is available from the United States Department of Agriculture (USDA) or other agencies in the form of maps that can be incorporated as a GIS layer. The Gridded SSURGO (gSSURGO) dataset from USDA is chosen. This dataset is similar to the standard product from USDA Natural Resources Conservation Service (NRCS) Soil Survey Geographic (SSURGO) database, but is in the Environmental Systems Research Institute, Inc. (ESRI®) file geodatabase format. A file geodatabase allows for statewide or even Conterminous United States (CONUS) tiling of data. The gSSURGO dataset contains all of the original soil attribute tables in SSURGO. All spatial data are stored within the geodatabase instead of externally as separate shape files. Both SSURGO and gSSURGO are considered products of the National Cooperative Soil Survey (NCSS). **Error! Reference source not found.** shows the unsaturated zone found by the difference between the groundwater elevation layer and surface topography.

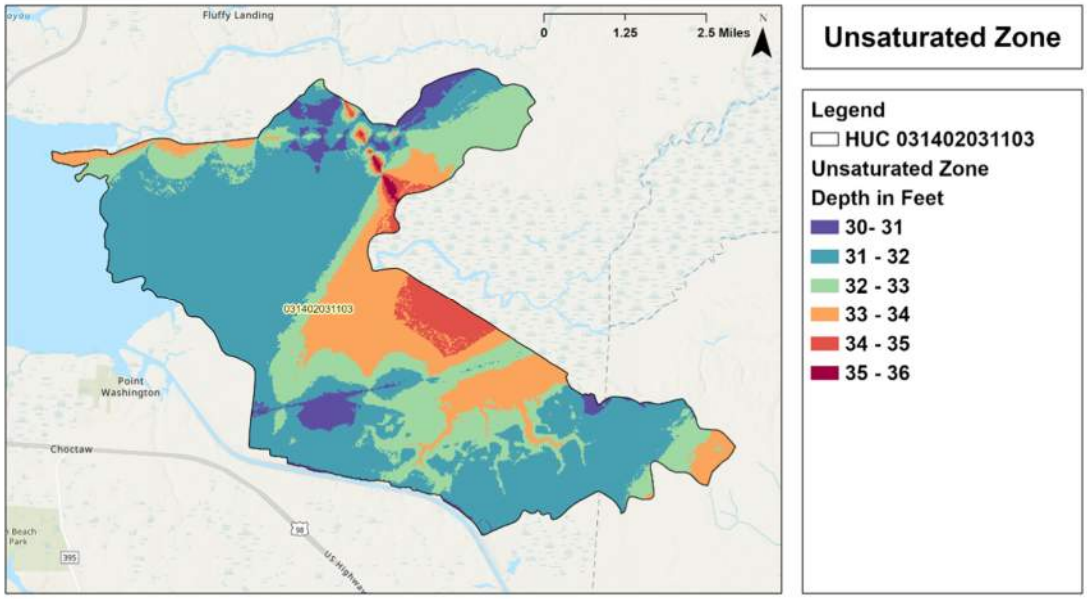

Figure 15. Unsaturated zone map for HUC 031402031103, processed by FAU.

The available water storage from USDA derived for the soil layer (0-150 cm or 0-5 ft) statewide is shown in **Error! Reference source not found.**, which covers most of Florida with a spatial resolution of 10 m. The unit is in cm. As a result of applying this layer to the study area (**Error! Reference source not found.**), the estimated soil storage capacity can be illustrated. A significant portion of the basin demonstrates a moderately favorable soil storage capacity, falling within the range of 31 to 35 feet of remaining capacity.

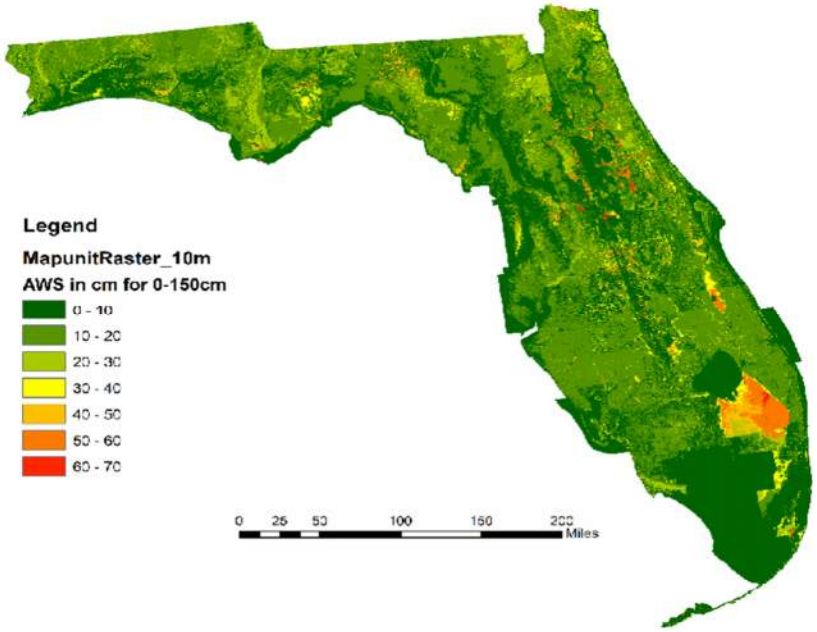

Figure 16. Available water storage derived from the gSSURGO soil database for all of Florida, as processed by FAU.
(Data Source: USDA - SSURGO)

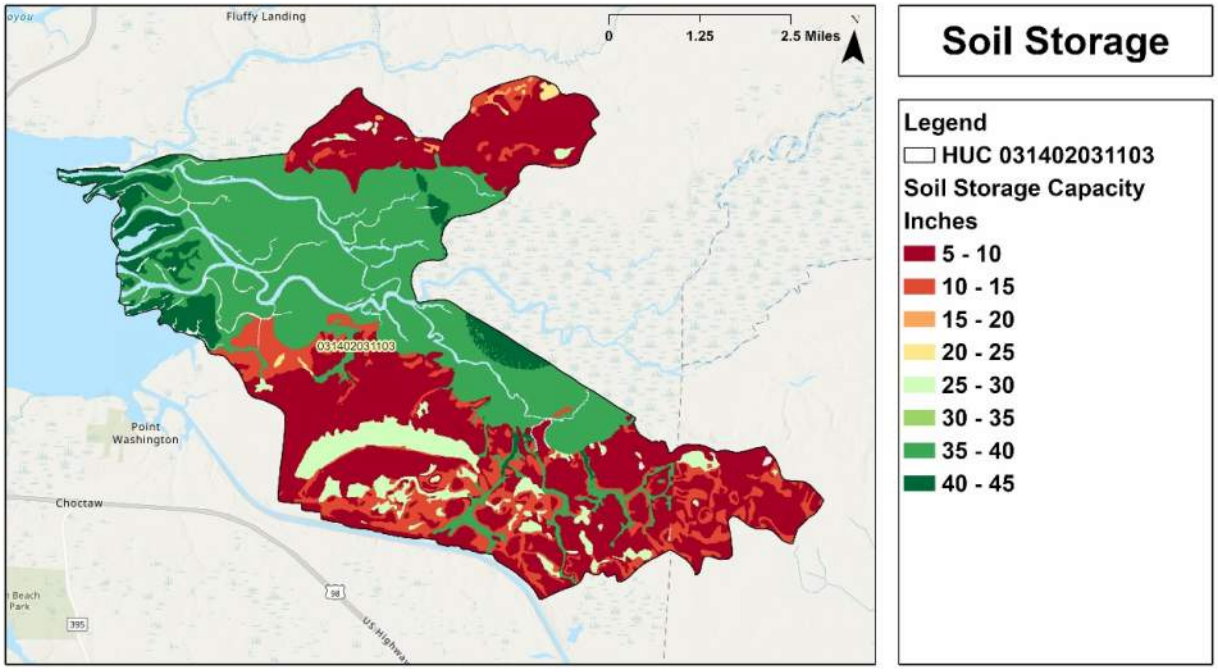

Figure 17. Water storage capacity of soil for the HUC 031402031103, processed by FAU.

Lastly, **Error! Reference source not found.** shows the water holding capacity for the basin, which refers to the capacity of a particular soil texture to retain water against the force of gravity.

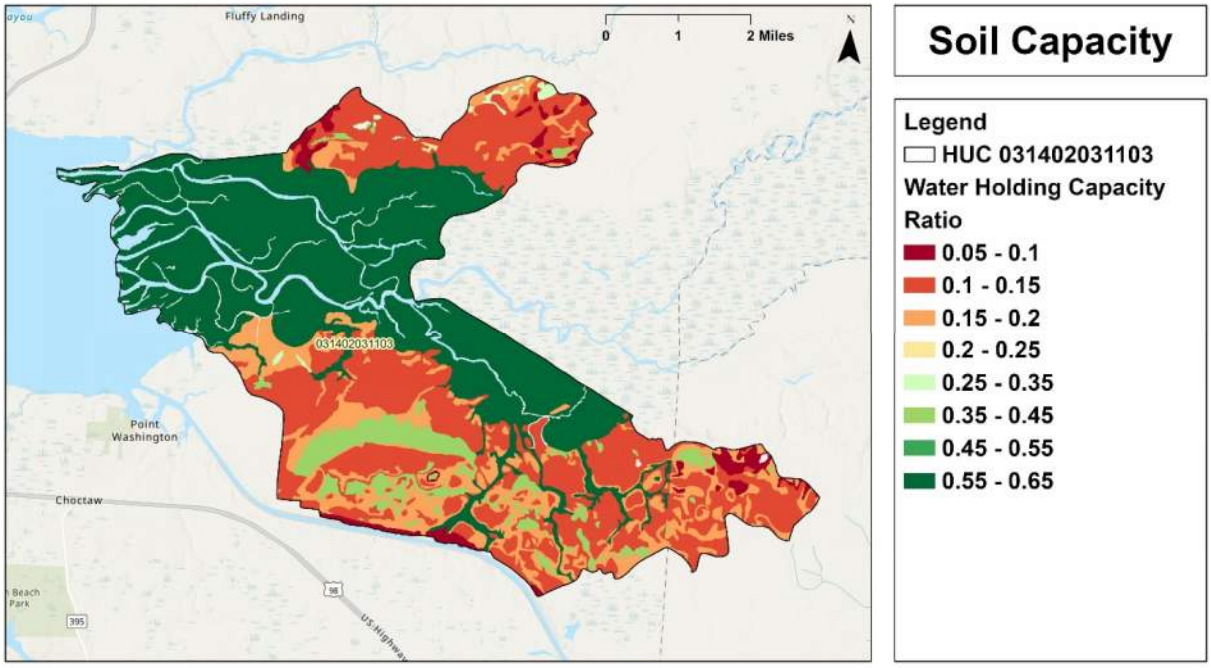

Figure 18. Water Holding Capacity (ratio) for the HUC 031402031103, processed by FAU.

1.5 Land Cover

The USGS produces the NLCD of nationwide data on land cover at a 30-m resolution with a 16-class legend based on a modified Anderson Level II classification system. NLCD is coordinated through the 10-member Multi-Resolution Land Characteristics Consortium (MRLC) to provide digital land cover information nationwide. For the conterminous United States, NLCD 2016 contains 28 different land cover products characterizing land cover and land cover change across 7 epochs from 2001-2016, urban imperviousness and urban imperviousness change across 4 epochs from 2001-2016, tree canopy and tree canopy change across 2 epochs from 2011-2016 and western U.S. shrub and grassland areas for 2016 (**Error! Reference source not found.**).

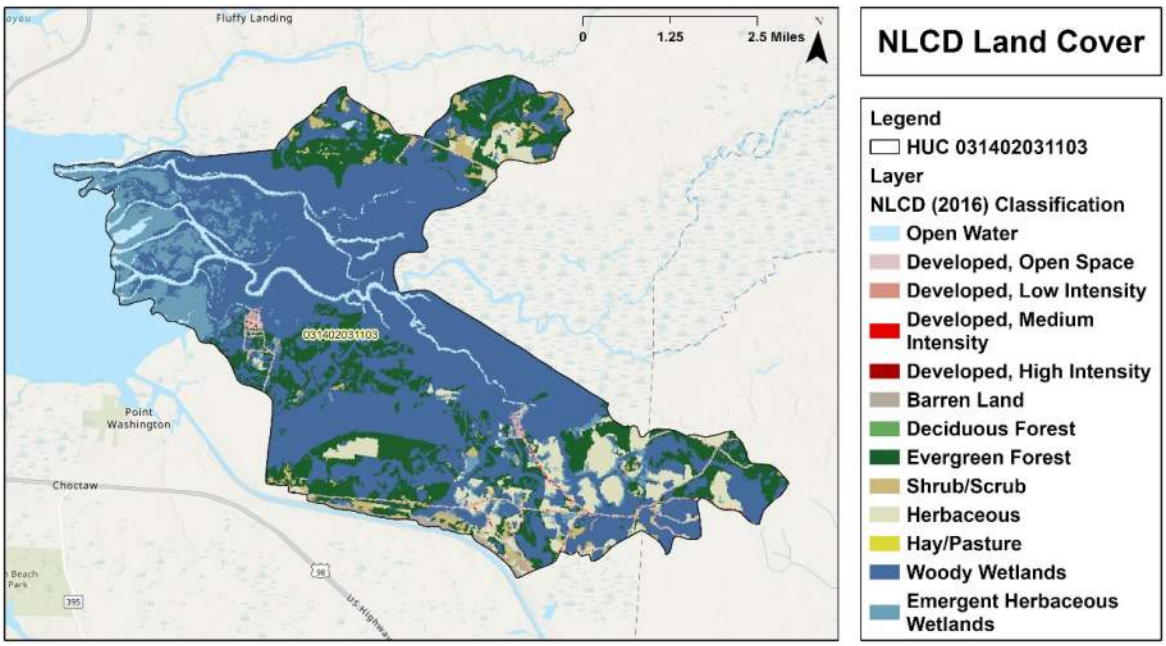

Figure 19. Land use in the HUC 031402031103 (from the NLCD 2016 database), processed by FAU.
(Source Data: NLCD, 2016)

The dataset is derived from the Florida Land Use Cover Classification System (FLUCCS), which is digitized by photo-interpretation on county-based aerial photography with varying resolution in the range of 4 in - 2 ft pixel. The NLCD2016 has a 30-meter resolution derived from Landsat imagery. Hence, the NLCD maps appear much coarser and pixelated compared to the 2023 Florida Geographic Data Library (FGDL) (https://fgdl.org/fgdlmap/) maps. A view of the latter is provided in **Error! Reference source not found.**. The future land use maps need to be used for the final land cover, as adjusted for future stormwater improvements set by regulatory standards.

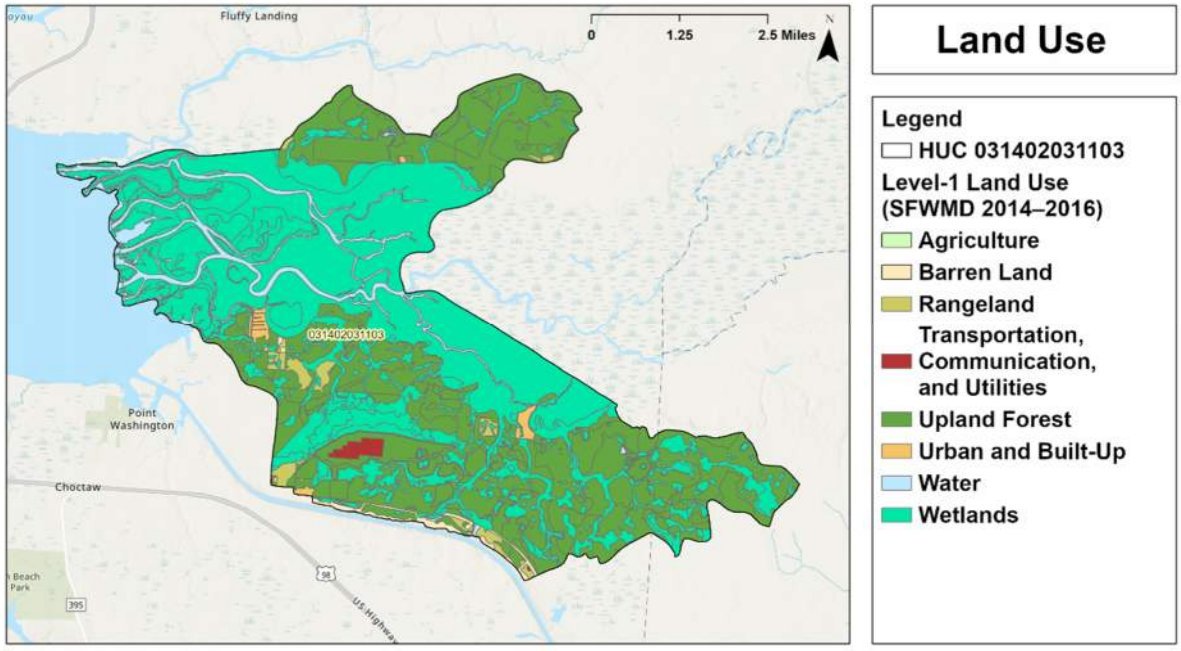

Figure 20. Land use in the HUC 031402031103, processed by FAU.
(Source Data: 2023 Florida Geographic Data Library (FGDL) database))

In the HUC 031402031103 sub-watershed, the predominant land cover is wetlands, accounting for 46.15% of the area. Upland forest comes in second at 36.84%, followed by water at 13.95. Developed land constitutes a minor portion, with only 0.48% categorized as urban and built-up, as indicated in **Error! Reference source not found.**. **Error! Reference source not found.** shows the roughness of the surface.

Table 3. Land use for HUC 031402031103 subwatershed

Level 1 Land Use Land Cover Type	**Area (Acres)**	**Percentage of Total**
Agriculture	8.36	0.02%
Barren Land	427.86	1.21%
Rangeland	375.30	1.06%
Transportation, Communication, and Utilities	101.47	0.29%
Upland Forest	13056.74	36.84%
Urban and Built-Up	171.80	0.48%
Water	4945.16	13.95%
Wetlands	16358.30	46.15%
Grand Total:	**35444.99**	**100.00%**

(Source Data: 2023 Florida Geographic Data Library (FGDL) database))

Table 4. Roughness and CN Values for Each Land Use Code.

DOR Code	Use	Impervious %	Roughness
0	Vacant	0	0.4
1	Single Family	29	0.25
2	Mobile homes	21	0.05
4	Condos	60	0.05
7	Vacant –to be developed	0	0.4
8	Multifamily	60	0.05
TH 101	Townhomes	91	0.025
94	Road Right-of-Ways	50	0.08
	Open water	100	n/a
All others	Commercial, etc.	50	0.07

1.6 Precipitation

Rainfall used in the screening tool is based on the SFWMD 3-day 25-year storm, but can be modified for any rainfall event using the accumulated rainfall table obtained from NOAA Atlas 14 Point Precipitation Frequency Estimates (https://hdsc.nws.noaa.gov/hdsc/pfds/pfds_map_cont.html). **Error! Reference source not found.** shows the 3-day 25-year rainfall map based on the NOAA Atlas 14 dataset for the whole state. **Error! Reference source not found.** to **Error! Reference source not found.** rainfall 1-day 100-year, 1-day 10-year, and 1-day 5-year storm event scenarios, in inches.

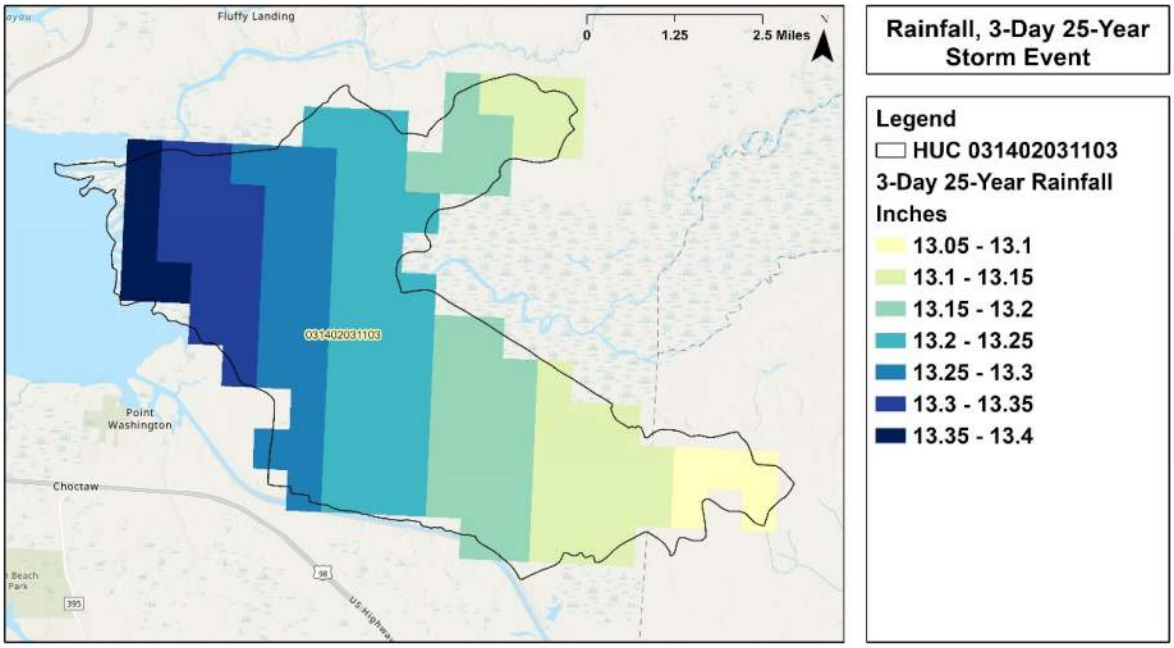

Figure 21. Rainfall distribution map across HUC 031402031103 sub-watershed, for 3-day 25-year storm event, processed by FAU.
(Source Data: NOAA Atlas 14 Database)

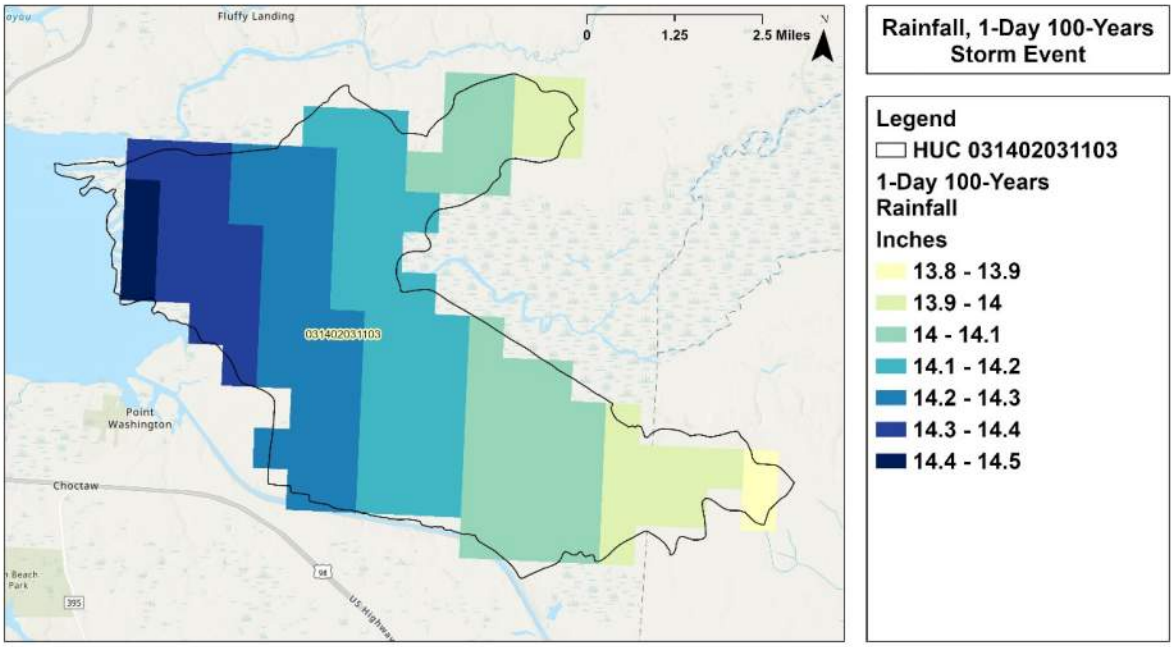

Figure 22. Rainfall distribution map across HUC 031402031103 sub-watershed, for 1-day 100-year storm event, processed by FAU.

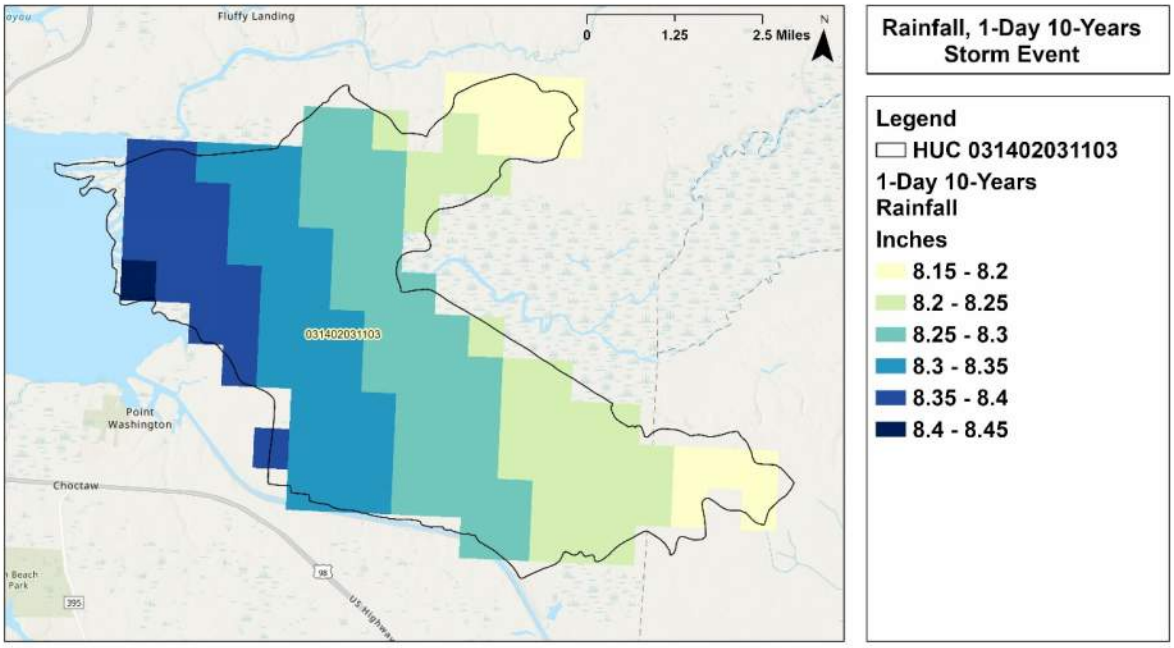

Figure 23. Rainfall distribution map across HUC 031402031103 sub-watershed, for 1-day 10-year storm event, processed by FAU.

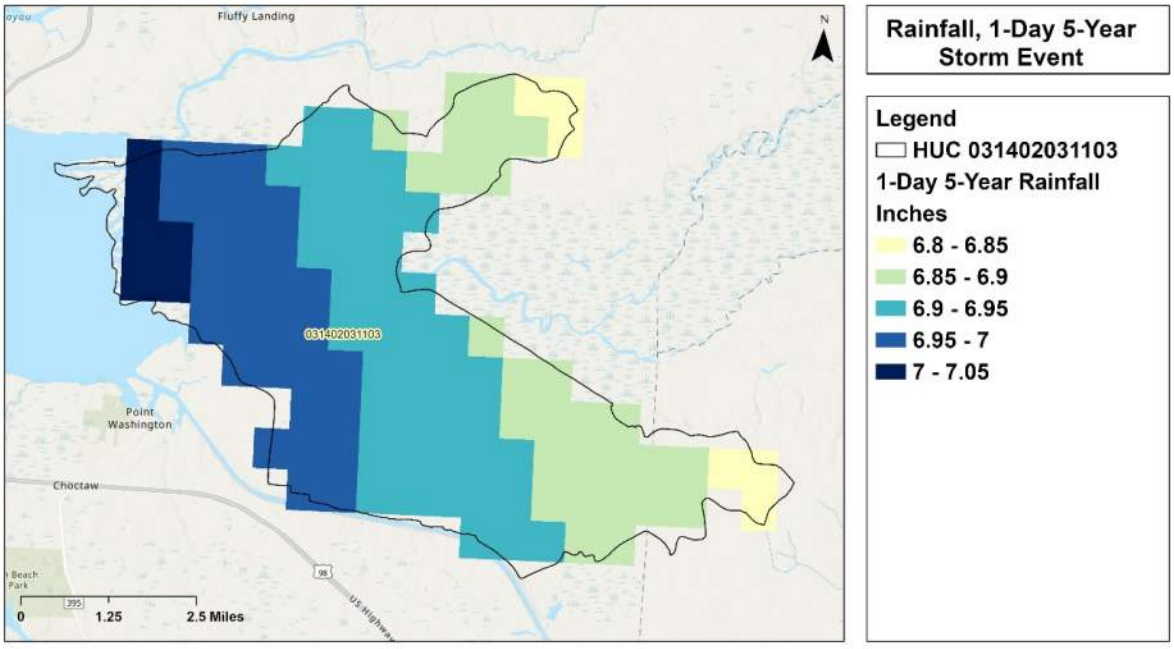

Figure 24. Rainfall distribution map across HUC 031402031103 sub-watershed, for 1-day 5-year storm event, processed by FAU.

1.7 Open Space

Open space is defined as areas that are exempted from development. Generally, this means one or more of the following qualifiers exist:

1. Land that is valuable for recreation, forestry, fishing, or conservation of wildlife or natural resources
2. Land that is a prime natural feature of the state's landscape, such as a shoreline or ridgeline
3. Land that is habitat for native plant or animal species listed as threatened, endangered, or of special concern
4. Land that is a relatively undisturbed example of an uncommon native ecological community
5. Land that is important for enhancing and conserving the water quality of lakes, rivers, and coastal water
6. Land that is valuable for preserving local agricultural heritage
7. Proximity to urban areas or areas with open space deficiencies and underserved populations
8. Vulnerability of land to development
9. Stewardship needs and management constraints
10. Preservation of forest land and water bodies that naturally absorb significant amounts of carbon dioxide

Permanent protection of sensitive areas can provide critical water quality protection and can be achieved through partnerships with landowners, municipalities, land trusts and state agencies. There is limited land in the study area that has been protected via acquisition by federal, state or local agencies, has conservation easements or is designated as wetlands or areas of critical concern. Agricultural land and other land cover will come from the land cover map (in Section 1.5). Added to this will be the water bodies discussed in Section 1.9, which serve a related condition to open space.

1.8 Impervious Areas

Impervious areas do not permit the infiltration of rainfall to groundwater, and because the water cannot infiltrate, it runs off faster. Faster runoff means that flows to water bodies and storm sewers occur faster and with higher peaks. The result is a disruption of the natural and potentially the planned hydrology. Impervious areas include pavement, buildings, and other areas that reduce runoff capacity. In other words, developed areas have much higher imperviousness than open spaces that are natural or agricultural.

The NLCD provides nationwide data on land cover and land cover change at a 30-m resolution with a 16-class legend based on a modified Anderson Level II classification system. Systematically aligned over time, the database offers the ability to understand both current and historical land cover and land cover change to enable assessment of trends. Using the NLCD 2016 dataset, a layer was created by using only three categories out of the 13 to identify impervious areas such as primary roads in urban areas, secondary roads in urban areas, and tertiary roads in urban areas. The new layer was then converted to match the 3-meter spatial resolution from the DEM and the standard State Plane Coordinate system. **Error! Reference source not found.** shows the impervious areas derived from the NLCD 2016 as updated by the future land use map.

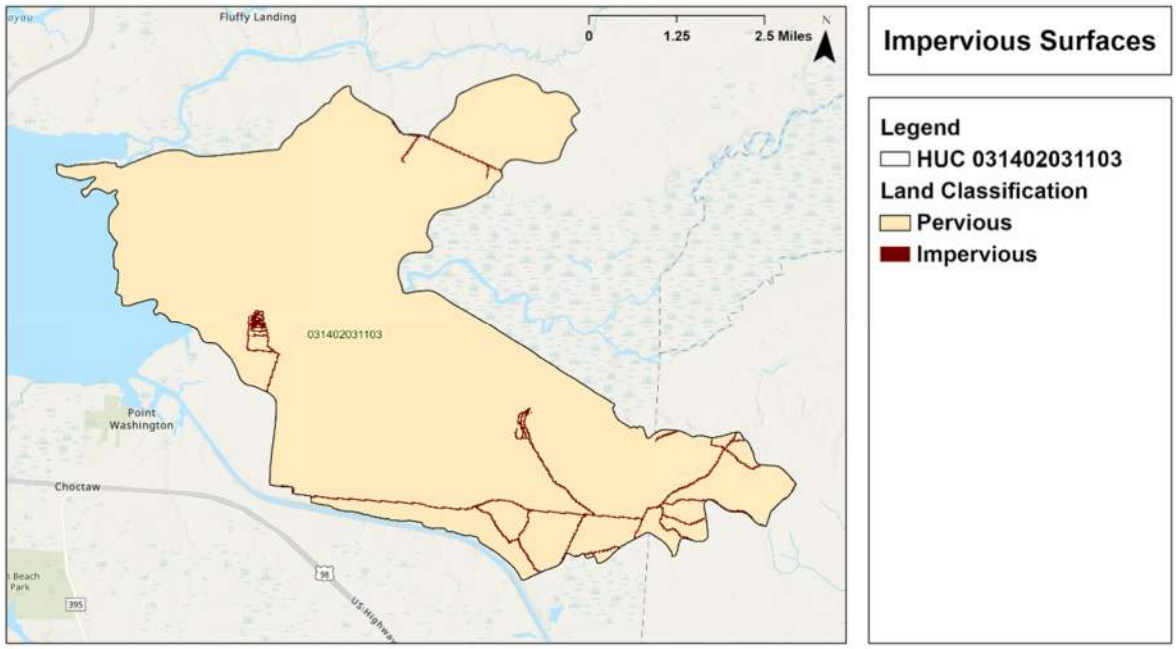

Figure 25. Impervious area map for the HUC 031402031103 sub-watershed, processed by FAU. (Source Data: NLCD, 2016)

1.9 Water bodies

Water bodies were defined in the statewide land use land cover dataset to set soil water holding capacity to zero in model simulations (**Error! Reference source not found.**). Note that tiny water bodies may be missing from the maps. Soils were discussed previously in Section 1.4.

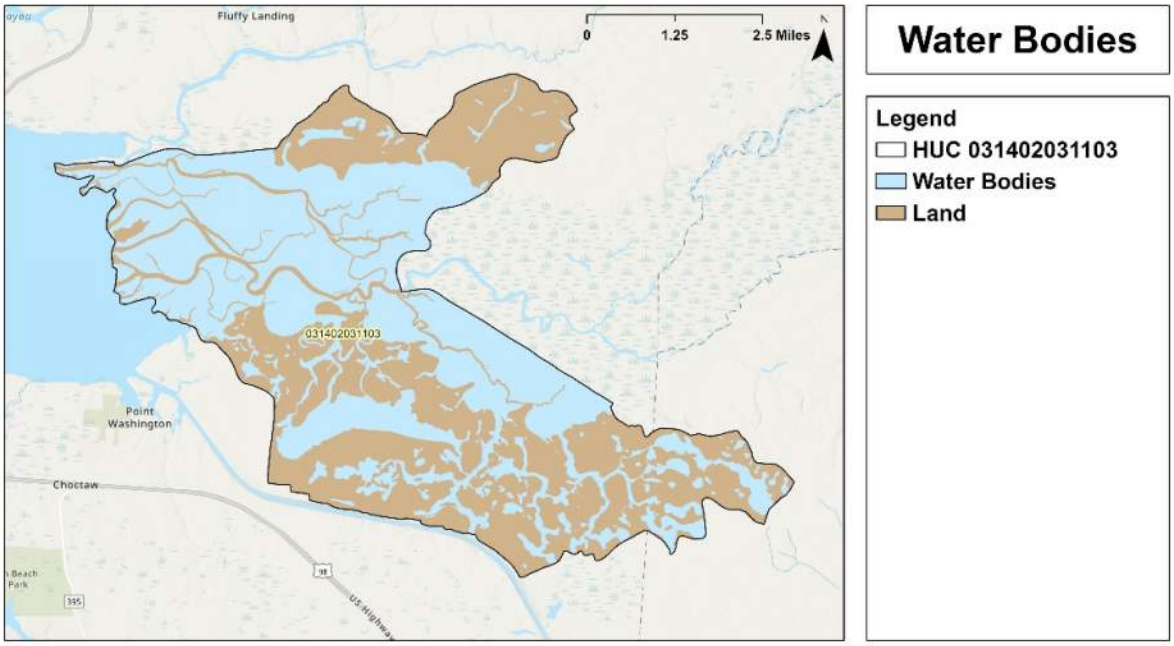

Figure 26. Water bodies map for the HUC031402031103 sub-watershed, processed by FAU. (Source Data: USEPA – National Hydrographic Dataset (NHD))

1.10 Natural Resources

Understanding the study area's natural resources is critical to identifying potential sources of water quality degradation and areas to designate for conservation, protection, and restoration. One possible goal of watershed master planning is to protect terrestrial wildlife, aquatic habitat, and buffer zones. USGS maintains important sources of information on physical and geographical features as well as soil and mineral resources, surface and ground water resources, topographic maps, and water quality monitoring data. The USDA's Natural Resources Inventory (NRI) (www.nrcs.usda.gov/technical/NRI) is a survey of information on natural resources on non-federal land in the United States that captures data on land cover and land use, soil erosion, prime farmland soils, wetlands, habitat diversity, erosion, conservation practices, and related items. Since 2001, the NRI has been updated continually with annual releases of NRI data from all 50 states. The information provided can be used for addressing agricultural and environmental issues down to the county or cataloging unit level. Therefore, this data can be used to determine erosion and site-specific soil characteristics for certain land uses such as croplands, pasturelands, forestlands, etc., but the data is typically provided as inventories, not GIS layers.

1.11 Demographics

Demographics data is important for determining several key indicators for watershed master planning such as the ability to pay for improvements, social justice issues, land acquisition costs, property/land use, and communication strategies. The US Census has databases at the census tract level. Based on the census data for the study area, **Error! Reference source not found.** outlines population and racial composition demographics.

Table 5. Demographics and Housing Characteristics of Cities and Towns in Walton County.

Demographic Parameter	**Miramar Beach**	**Freeport**	**DeFuniak Springs, City**	**Paxton**	**Rosemary Beach**	**Santa Rosa Beach***	**Walton County**
Type	CDP**	City	City - County Seat	Town	Unincorporated community		County
Area in square miles	7.02	18.94	13.95	4.01	17,021	68,722	1,038.29
Population (Census 2020)	8,002	5,861	5,919	556	2,878	20,567	75,305
Total Households	4,334	2,206	2,509	316	1,318	8,275	30,182
Median Household Income	$75,347	$75,637	$53,984	$41.750	$127,148	$94,648	$68,111
Median Age	56.3 years	41.4 years	37.1 years	50.6 years	52.4 years	43.20 years	45.0 years
White	7,688	2,086	4,021	482	2,638	17,268	89.8%

*It includes the communities of Point Washington to the East and a 15-mile stretch of the Emerald Coast from the east side of Miramar Beach to the west side of Seagrove Beach and the beach communities along 30A, including Grayton Beach and Seaside.

** Census Designated Place

1.12 Stormwater Infrastructure Inventory

Local community stormwater systems consist of drainage ditches, storm sewers, retention ponds and other facilities constructed to store runoff or carry it to a receiving stream, lake, ocean, or other waterbody. Other man-made features include yards and swales that collect runoff and direct it to the sewers and ditches. When most of these systems were built, they were typically designed to handle the amount of water expected during a 10-year storm. Larger storms overload them, and the resulting backed-up sewers and overloaded ditches produce shallow flooding. Another urban drainage problem occurs in the areas protected by levees. Being in floodplains, they are flat and do not drain naturally, especially when a levee blocks the flow to the river. To drain these areas, channels have been built and pumps installed to mechanically move the water past the levee. Often, these man-made systems do not have the capacity to handle heavy rains or intense storms.

Another challenge with stormwater infrastructure is related to recordkeeping. It is not uncommon for stormwater data to be incomplete in most jurisdictions and completely lacking in others. Quality of data differs from jurisdiction to jurisdiction; some are in GIS formats, while others are paper maps or as-builts that represent the infrastructure at a macroscale level. The condition of the assets may be lacking, and the maintenance history may not be available either. Stormwater assets may have been installed with no records, especially in rural areas, farm fields, and private property.

Walton County passed Ordinance No. 2008-06 that prohibits unauthorized discharges into storm drains or ditch systems. In addition, the Public Works Division is currently running a continuous public awareness campaign aimed at encouraging the adoption of best management practices (BMPs) for managing stormwater runoff. This initiative targets both the business community and the residents of Walton County.

To address the issue of flooding, Walton County has implemented several measures along the years, such as:

- Drainage Systems: The county has invested in the development and maintenance of drainage systems, including ditches, canals, and retention ponds, to manage stormwater runoff and reduce flood risk.
- Floodplain Management: Walton County has adopted floodplain management regulations and participates in the National Flood Insurance Program (NFIP) to encourage responsible development in flood-prone areas.
- Elevation Standards: New construction projects within flood zones are required to adhere to specific elevation standards to minimize potential flood damage.

- Emergency Response: The county has established emergency response plans to assist residents during flood events, including evacuation procedures and the provision of emergency shelters.

Key stormwater assets for the HUC and Walton County are indicated in **Error! Reference source not found.** and **Error! Reference source not found.**, respectively. Stormwater structures and management processes in the county consist of stormwater outfall, water wells, weir, pollutant control boxes, inlets catch basins, pipes culverts, ditch conveyance swales, structures, pipes and open conveyance.

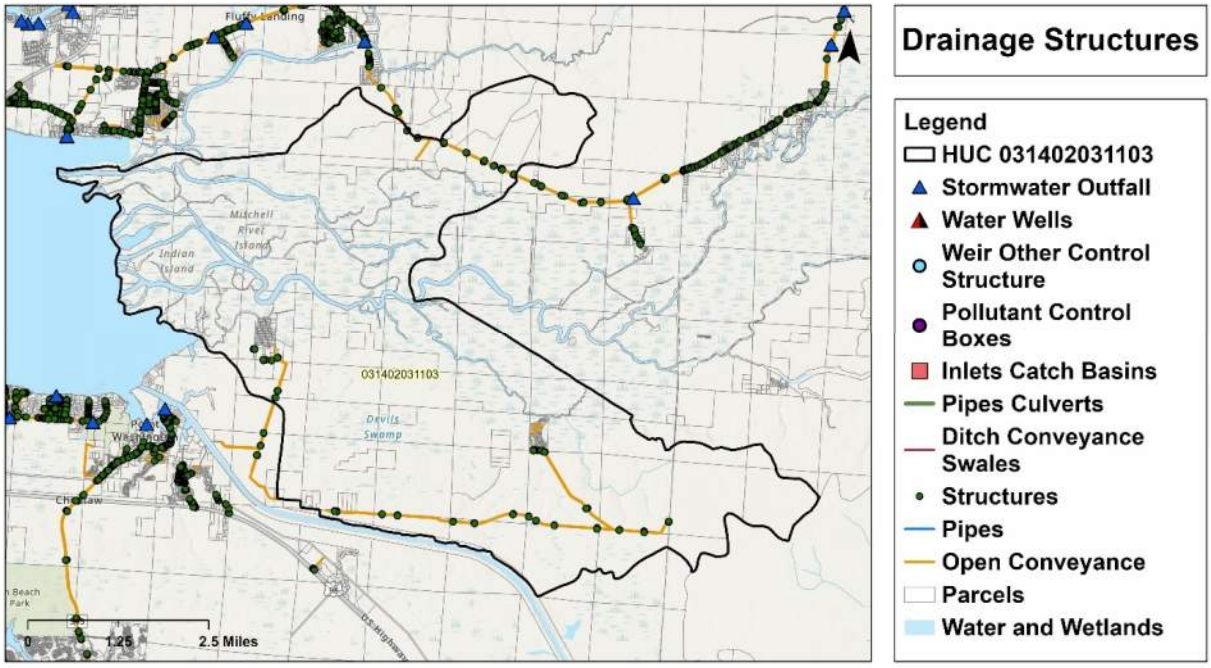

Figure 27. Stormwater Infrastructure for the HUC 031402031103. Processed by FAU.
(Source Data: Walton County Storm Asset Inventory and Stormwater Inventory)

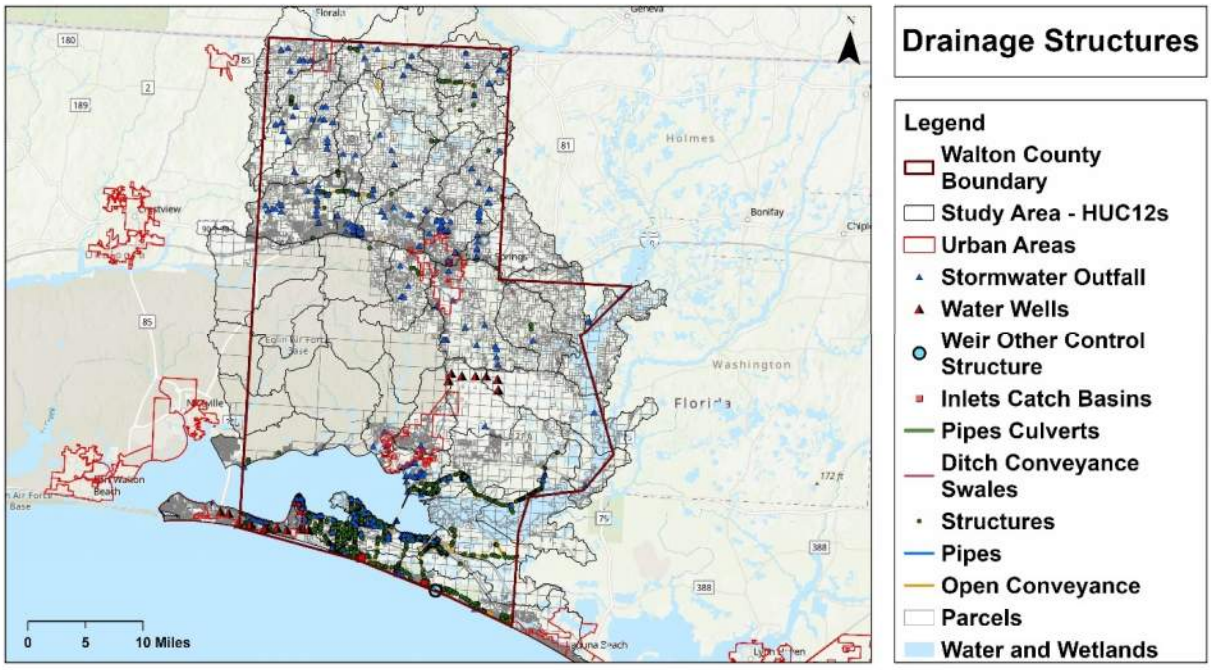

Figure 28. Stormwater Infrastructure for Walton County. Processed by FAU.
(Source Data: Walton County Storm Asset Inventory and Stormwater Inventory)

Although nature-based infrastructure might be installed, it is not certain. The stormwater system must maintain compliance with the stormwater regulations, which requires record-keeping, policy development, inspections and maintenance. The goals of such stormwater management may include:

- Best landscape practice;
- Control car washing contribution to pollution;
- Enforce the Stormwater Pollution Prevention Plan (SWPPP) by site evaluation, assessment, erosion and sediment controls, preventive maintenance, certification and inspection reporting for construction sites and city planning;
- Implement a hazardous material elimination system;
- Eliminate illicit dumping;
- Proactive and reactive catch basin inspections and maintenance;
- Street sweeping to control debris;
- Maintain swales to help prevent stormwater pollution flooding.

1.13 Data Gaps

FAU has developed comprehensive databases to address the information needed for the vulnerability assessment. These are included in Table 6. The data can be used to model the impacts

of flood routing during the storm of interest. As a result, the modeling pieces (discussed in Chapter 2) will include the following:

- Flood response model results (Cascade 2001)
- Flood risk/hazard mapping
- Vulnerability assessments to identify areas of concern for future repetitive losses

There is only one data gap for the area – existing stormwater infrastructure records are incomplete. However, for the purposes of this plan, this data gap does not limit the findings, as there are two scales: 1) the sub-watershed level and 2) community hotspots. A neighborhood level vulnerability assessment will require the local infrastructure inventory.

Table 6. List of datasets collected by FAU as of List of datasets collected by FAU for the project (12/20/2020).

2.0 ASSESSMENT OF VULNERABLE AREAS

Defining flood risk due to compounding hydrographic influences is the central concern of this WMP. Modeling and assessment of vulnerability focused on the combination of a high-water table, heavy rains, and impervious conditions that can lead to localized nuisance flooding events. Through a previous survey with local officials, the number of days of continuous nuisance flooding that the public will tolerate before that flooding is considered destructive is about 4 days (E Science 2014).

For a large study area, small parts may actually be at risk. The point is to identify where further study might be needed. A screening tool accomplishes this goal applied to the sub-watershed scale to designate areas that are susceptible to periodic flooding events. Utilizing the information collected and analyzed in Chapters 1, analysis of flood vulnerability can be performed.

2.1 Historical and Existing Challenges

Walton County has faced various historical and existing challenges as well as natural hazards over the years. Some of these include:

- Hurricane and Tropical Storms: being situated along the Gulf Coast, Walton County is vulnerable to hurricanes and tropical storms, which can lead to damage to the built and natural environment, as well as poses risks to human and wild life.
- Coastal Erosion: The county's coastline is subject to erosion due to natural processes and human activities. Erosion can lead to the loss of beaches and threaten coastal structures and properties.
- Flooding: heavy rainfall, storm surges from hurricanes, and other factors can cause localized flooding, particularly in low-lying areas. Flood events can disrupt daily life, damage property, and impact transportation.
- Water Quality and Quantity: as in many coastal areas, managing water quality and maintaining an adequate water supply are ongoing challenges. Pollution from stormwater runoff and other sources can affect water quality, and groundwater resources need to be carefully managed to sustain the growing population.
- Wetland Loss: The county's wetlands face the threat of degradation and loss due to urban development and other human activities. Protecting these essential ecosystems is vital for maintaining biodiversity and mitigating flood risks.
- Urbanization and Development: Balancing the demand for development and growth with the preservation of natural habitats and resources is a persistent challenge. Unplanned

urbanization can lead to habitat destruction, increased runoff, and exacerbate flooding risks.

- Land Use and Zoning: Proper land use planning and zoning are essential to address issues related to population growth, infrastructure development, and natural hazard mitigation. Ensuring responsible development practices can help minimize risks.
- Invasive Species: Like many regions, Walton County faces the threat of invasive plant and animal species. These invasive species can disrupt local ecosystems, negatively impacting native flora and fauna.
- Sea-Level Rise: With rising sea levels due to climate change, coastal communities like Walton County's coastal areas are at greater risk of inundation and storm surges during extreme weather events.

The fast growth of the population and urban development in the coastal areas of the county exacerbates effort to protect open space for land percolation of water. While regulations are in place to reduce the influx of stormwater, the challenges will continue with development.

2.1.1 Existing Management Efforts in the Watershed

The county is under Northwest Florida Management District (NWFMWD) jurisdiction, which covers the Florida Panhandle region. The NWFMWD is responsible for managing and protecting water resources in its designated regions, which includes issues related to water supply, water quality, flood control, and natural resource conservation. Local governments have local stormwater utility infrastructure and planning/policy tools to reduce future flood potential. Most of the major projects to date have been focused on addressing the water quality issues and flooding due to extreme rainfall.

2.1.2 Critical Target Areas Identification

By modeling the HUC 031402031103 sub-watershed flood response to a series of rainfall events and sea levels (plus king tides), and further classifying flood risk as the probability of inundation, it is possible to identify critical target areas. These areas are particularly vulnerable to flooding and are subject to further study through a scaled-down modeling approach. The screening tool is first applied at the greater watershed level to provide an initial risk assessment focused on the hydrologic response to a rainfall event given the unique characteristics and features of the sub-watershed or study area. The process is discussed later in Section 2.2 with results presented in Section 2.4.

2.1.3 Potential Preservation Areas

Walton County boasts several areas with high biodiversity value. These areas include the unique coastal dune lakes, which support diverse ecosystems and contribute to water quality along the coast. Wetlands are crucial habitats that provide refuge for a variety of plant and animal species while acting as natural water filters. State parks like Topsail Hill Preserve and Grayton Beach State Park are valuable conservation areas with diverse coastal ecosystems. Additionally, preserving the Choctawhatchee River Basin is essential for the biodiversity of the region.

2.2 Vulnerability Maps

2.2.1 Screening Tool

The screening tool utilizes topographic data from various sources (Section 1.1), water table elevations (Section 1.2) and surface water gauges (Section 1.3) downloaded from the NWFWMD DBHYDRO website, tidal information for coastal areas obtained from the NOAA Current & Tides website (Section 1.3), soil maps obtained from the USDA (Section 1.4), and another key dataset as described previously in Chapter 1. The design storms are discussed in Section 1.6. The reason this is critical is that to do any modeling (as required by the CRS program), a screening tool should be used to identify regions with a high risk of inundation based on multiple collected datasets and hydrological models. **Error! Reference source not found.** shows how the GIS layers interface in the tool and how they are combined for spatial analysis.

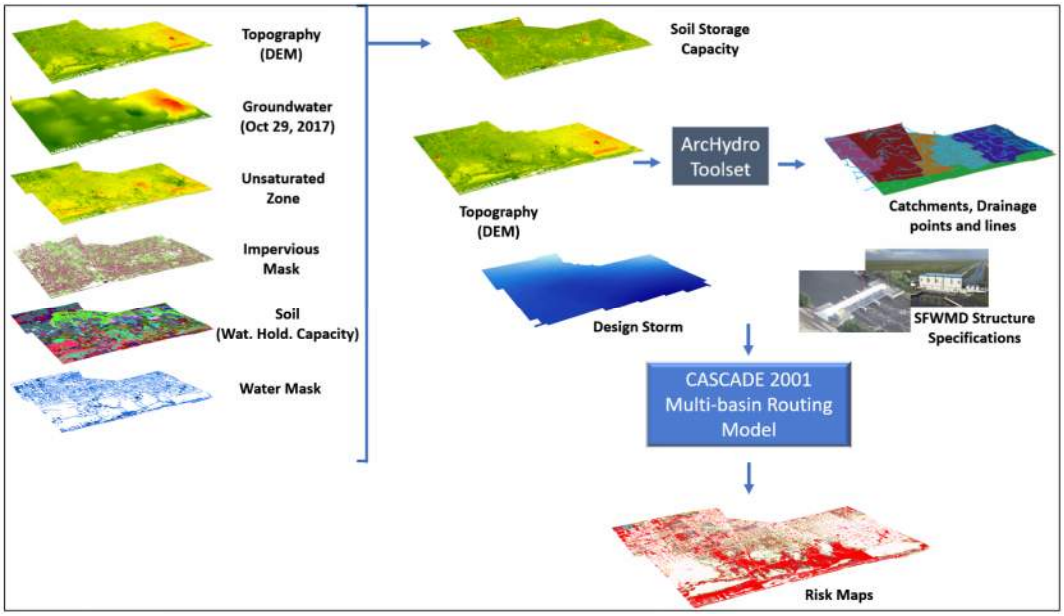

Figure 29. Screening tool methodology for creating flood risk maps.

The model chosen for this screening tool is Cascade 2001, which is a multi-basin hydrologic/hydraulic routing model developed by the SFWMD. The model permits the

investigator to run different storm events to determine flooding scenarios. The boundaries are critical for basin studies and must be chosen carefully. The following data layers collected in the prior section are processed to develop the input files for Cascade 2001:

- Topography
- Soils
- Development intensity
- Groundwater elevations
- Surface water/Outlet locations

The software creates a glass box where water rises to a certain level and then decreases. Running the simulation requires defining the basin (HUC or sub-HUC) and input of the following data:

- Area
- Portion of area above a given elevation
- Initial groundwater stage
- Longest travel time for the runoff to reach the most distance point of discharge
- Ground storage as estimated from the USDA gridded National Soil Survey Geographic Database (gNATSGO)

  Ground storage ≈ (Water holding capacity) × (Surface elevation – GW elevation)
  = 2 × (AWS for a soil layer of 0-150 cm) / 150cm × (Surface elevation – GW elevation)

- Available water storage (AWS) for a soil layer of 0-150 cm
- Average amount of precipitation that can be stored in the soil layer

The output from the model is an elevation surface that can be used to develop a flood map for the study area (**Error! Reference source not found.**), which shows the spatial distribution of probabilities of flooding during the modeled 1-day 100-year storm event.

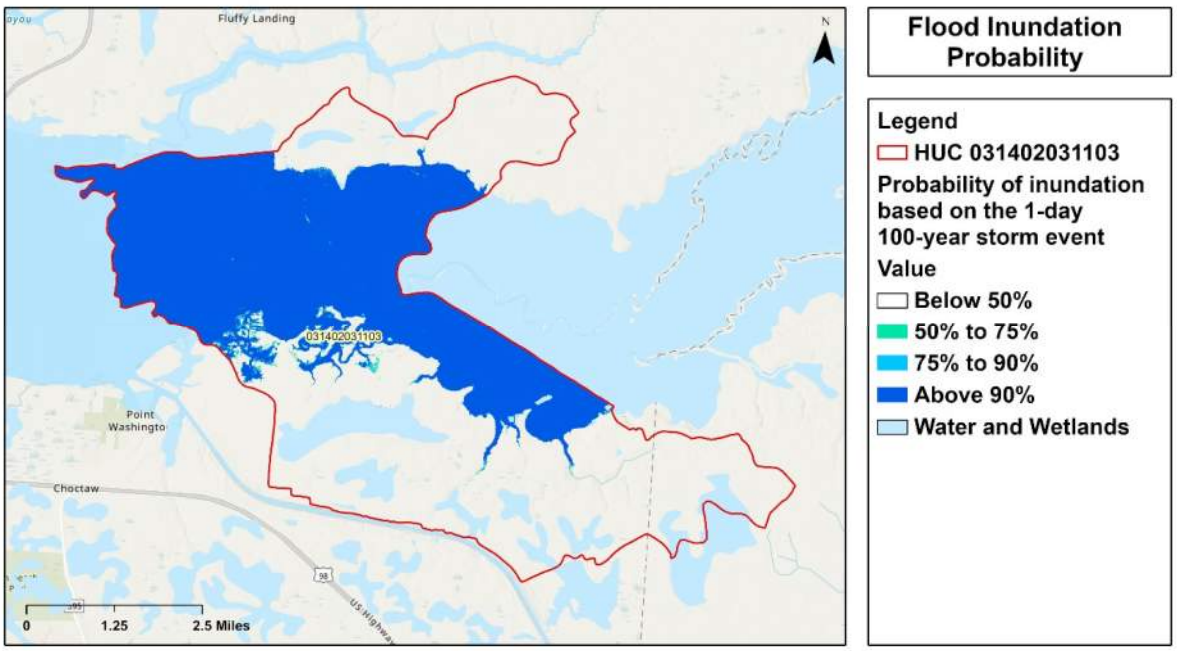

Figure 30. Probability of flood risk map during the modeled 1-day 100-year storm event for the HUC 031402031103, processed by FAU.

2.2.2 Identification of Vulnerable Areas

Given these assumptions and the Cascade 2001 outputs, the goal of this methodology is to produce a spatially-temporally quantified understanding of nuisance-destructive flood potential in the study area given observed values. Risk is a function of compounding geo-hydrological features, namely, surface water, groundwater, topography, build-out, and time of year. A GIS-based algorithm and spatial interpolation generated layers of the greatest observable hydrographic surfaces. These outputs were then compared with high resolution topographic LiDAR data to develop digital elevation models that reflect the observed risk landscape. These models can then be combined into Cascade 2001 to produce vector and volume information, in combination with soils, vegetation and impervious surfaces, allowing the observed model outputs to be extrapolated into a more predictive context.

To evaluate flood vulnerability at this scale, the analysis starts with a binary flooding surface (0 = below 50% chance of flooding; 1 = above 50% flooding) based on output from the screening tool for a specified design storm. Next, attributes of that raster based on "VALUE = 1" query are extracted using *Extract by Attributes* tool. Then the *Batch Project* tool was used to map critical facilities data to the common coordinate system (NAD83 UTM Zone 17N), unit = meters. Then a field was added using *Add Field* for [PriorityTier] = assigned Tier #1-4 value from the DOR codes and [Area_sqmeter]. The critical facilities layers were then merged into a single layer to calculate

the polygon geometry for [Area_sqmeter] using the *Merge* tool. Next, *Zonal Statistics as Table* is used to calculate the SUM of flooded values ("VALUE = 1") within each critical parcel. Output table has fields for SUM (i.e., total # of flooded pixels per critical parcel) and AREA in map units of square meters (since each pixel in the flooding surface has a cell size of 3-meters by 3-meters, each area is equal to the SUM value multiplied by 9 m^2). Using the *Join Field* tool, the SUM and AREA fields are joined to the merged critical facilities layer based on a key attribute, first renaming these fields for clarity (e.g., AREA_FLOODED_3d25y). Once all field data is included, the next step involves using *Export Table* to export the dataset as a CSV file. Note that non-flooded parcels have zero flooded area, so they receive a <Null> value from the zonal statistics tool. To replace null values with zeros, we use *Calculate Field* in the attribute table along with the following Python expression (replacing the respective field name): "0 if !AREA_FLOODED_3d25y! is None else !AREA_FLOODED_3d25y!". Next, the CSV file is saved as an Excel Workbook (.xlsx). The Range is converted to an Excel Table, and the columns are rearranged in the desired order. Finally, the "percent-flooded" columns are calculated as follows:

- PCT_FLOODED_3d25y = ([@[AREA_FLOODED_3d25y]]/[@[TotalArea_sqmeter]])*100
- PCT_FLOODED_1d100y = ([@[AREA_FLOODED_1d100y]]/[@[TotalArea_sqmeter]])*100

After this calculation, the table is sorted to show the higher priority tiers and higher percent-flooded values first. To reduce the number of critical facilities shown in the final table, a filter was created to show only critical facilities with 10% or more flooded area in the parcel during both storm events. Records with duplicate parcel ID numbers were removed from the table. The results of this procedure are discussed in Section 2.5 of this document.

With respect to dams and levees, for purposes of the NFIP, FEMA only recognizes systems that meet, and continue to meet, minimum design, operation, and maintenance standards that are consistent with comprehensive floodplain management criteria. The Code of Federal Regulations, Title 44, Section 65.10 (44 CFR 65.10) describes the information needed for FEMA to determine if a levee system reduces the risk from the 1% annual chance flood. FEMA has accredited levees and Provisionally Accredited Levees (that have a specified timeframe to obtain the necessary data to confirm the levee's certification status). If a levee system no longer meets Section 65.10, FEMA will de-accredit the levee system and issue an effective FIRM showing the levee-impacted area as a SFHA. FEMA coordinates its programs with USACE, who may inspect, maintain, and repair levee systems. USACE has authority under Public Law 84-99 to supplement local efforts to repair flood control projects that are damaged by floods. Like FEMA, USACE provides a program to allow public sponsors or operators to address levee system maintenance deficiencies. Failure to do so within the required timeframe results in the levee system being placed in an inactive status in the USACE Rehabilitation and Inspection Program. Levee systems in an inactive status are not

eligible for rehabilitation assistance under Public Law 84-99. There are no levees/dams listed in the sub-watershed study area.

2.3 Future Challenges of Sea Level Rise and Climate Change

Global observations from satellites and long-term data collection have made it possible to document and analyze patterns in the Earth's climate. Scientific analysis of the impact of these changes has helped to improve the understanding of future flood hazard driving forces and long-term impacts on human activities and watershed master planning (http://www.research.noaa.gov/climate/t_observing.html). Examples of impacts are rising global average air and ocean temperatures, increased and earlier snow and ice melt, shorter subtropical rainy seasons, shifted seasons, sea level rise and greater variations in temperature and precipitation (IPCC, 2013; Freas et al., 2008; Marshall et al., 2004; Bloetscher et al., 2010). Marshall et al. (2004) specifically focused on the Florida peninsula to predict changes in rainfall and warmer temperatures but interspersed lower low temperatures due to the potential loss of wetlands.

Future changes in climate will add to the existing impacts, at a time when the population of the state is expected to nearly double by 2030. Additional research and high-resolution climate modeling for the Florida peninsula and local jurisdictions is needed to help guide long-term plans like WMPs. Rainfall appears to be decreasing and temperatures rising (see **Error! Reference source not found.**).

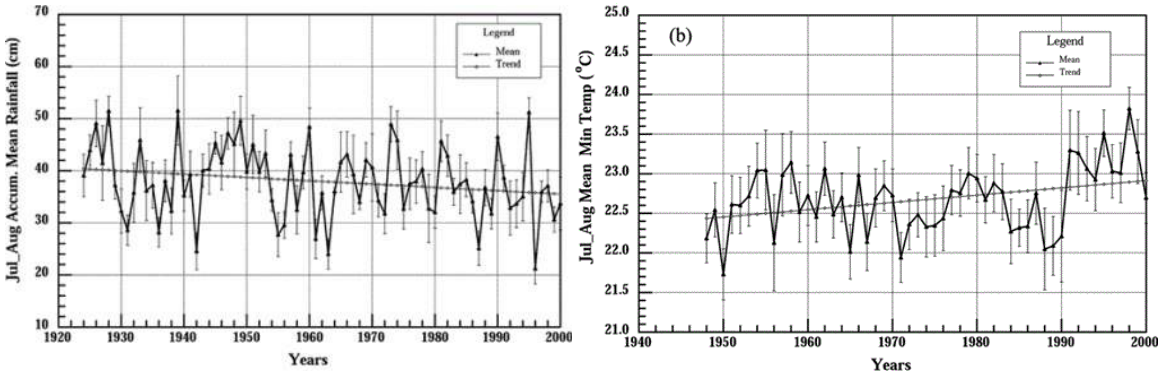

Figure 31. Change in average rainfall and change in average temp 1924 to 2000. Note the reversed trend, which means groundwater input variability is lessened.
(Source: Marshall et al., 2004)

Climate change is likely to: 1) threaten the integrity and availability of fresh water supplies and 2) increase the risk of flooding, not only in the low-lying coastal areas, but also in the interior flood plains. Other issues include a) saltwater intrusion, which may be intensified by sea level rise, b) prolonged droughts that will contribute to water supply shortages and wildfires, and c) heavier

rains during the rainy season and higher hurricane storm surge, which may increase the risk due to flooding. More frequent and damaging floods are likely to become an ever-increasing problem as sea level continues to rise because of: a) increasing groundwater table elevations and surface water gage heights, b) reduced groundwater seepage through the aquifer to the ocean, c) increasingly compromised stormwater drainage systems, and d) more frequent inundation of barrier islands and coastal areas.

NOAA and IPCC (2013) predictions suggest that by 2100, global temperatures will be on the order of 2-3°C (3-5°F) higher and sea levels will rise by up to 3 feet. Accompanying these drivers are potential changes in storm frequency and intensity, desertification, population migration, ocean acidification and coastal flooding (IPCC, 2007), exacerbated by the land cover and land use changes, which are substantially impacted by the fluxes, timing and quality of precipitation (Adrians et al., 2003; Scanlon et al., 2005; Marshall et al., 2004; Salmun and Molod, 2006), and leading to changes in the timing of peak flows and volumes (Richey and Costa-Cabral, 2006).

The results of these climatic changes are likely to: 1) threaten the integrity and availability of fresh water supplies and 2) increase the risk of flooding, not only in the low-lying coastal areas, but also in the interior flood plains. Other issues include a) saltwater intrusion, which may be intensified by sea level rise, b) prolonged droughts that will contribute to water supply shortages and wildfires, and c) heavier rains during the rainy season and higher hurricane storm surge, which may increase the risk due to flooding. More frequent and damaging floods are likely to become an ever-increasing problem as sea level continues to rise because of: a) increasing groundwater table elevations and surface water gage heights, b) reduced groundwater seepage through the aquifer to the ocean, c) increasingly An outcome of these climatic patterns is that during the past 140 years, an increase in sea levels has been observed (Bloetscher, 2012), a worrying pattern since sea level rise is a permanent phenomenon, that can be catastrophic to low lying areas in the long-term. The question is how much and how soon? Various studies (Bindoff et al., 2007; Domingues et al., 2008; Edwards, 2007; Gregory, 2008; Vermeer and Rahmstorf, 2009; Jevrejeva, Moore and Grinsted, 2010; Bloetscher, 2010, 2011; IPCC, 2007; Heimlich et al., 2009) indicate large uncertainty in projections of sea level rise by 2100. Gregory et al. (2012) note that during the last two decades, the global rate of sea level rise has been larger than the 20th-century time-mean, and Church et al. (2011) suggested that the cause was increased rates of thermal expansion, glacier mass loss, and ice discharge from icesheets. Gregory et al. (2012) suggested that there may also be increasing contributions to global sea level rise from the effects of groundwater depletion, reservoir impoundment, and loss of storage capacity in surface waters due to siltation. Measurements of Florida's east coast (Maul, 2008) show an average rate of sea level rise of 2.27 ± 0.04 mm per year from 1915 to 1992 based on tide gauge readings. Analyzing the tidal gauge readings for Florida shows that:

1. Florida average sea level rise is 2.10 ± 0.49 mm/yr

2. All but one location is within the 95% confidence limit range (the exception is Panama City where there is evidence of submergence and other land-based issues)
3. None of the Florida sea level rise rates differ statistically
4. Average global sea level rise for 1920-2000 was 2.0 mm/yr – within 95% confidence limit for Florida locations

From 1929 to 1992, over eight inches of sea, with another 6 inches added since 1992, which is already having significant impacts on coastal communities where population growth has increased the need for improved flood management strategies (Bloetscher, 2008; Parkinson, 2010; Zhang et al., 2011, 2011a; NFIP, 2011; Schmidt et al., 2011; Warner et al., 2012).

As a result, the SFRCCC (2015) adopted USACE's methodology to derive scenarios of sea level change intermediate to high rates of sea level rise for years 2030 (3" to 7") and 2060 (9" to 24") as the consensus projection to guide future planning. The path keeps increasing – now 14 inches since 1929 (**Error! Reference source not found.**) caused by thermal expansion of the ocean and melting ice caps (Jevrejeva et al., 2010; Vermeer and Rahmstorf, 2009). Sea level rise is a major concern in Florida, including Walton County, since the majority of the state's population live on the coast, involving most major commercial, residential, and economic enterprises. **Error! Reference source not found.** demonstrate the estimated sea level change for Panama City, considering the predictions of NOAA 2017. For NOAA high scenario SLR change scenario, the estimated level change is higher than 8 ft., while for the intermediate and low scenarios are about 3.9 feet and 1.7 feet respectively.

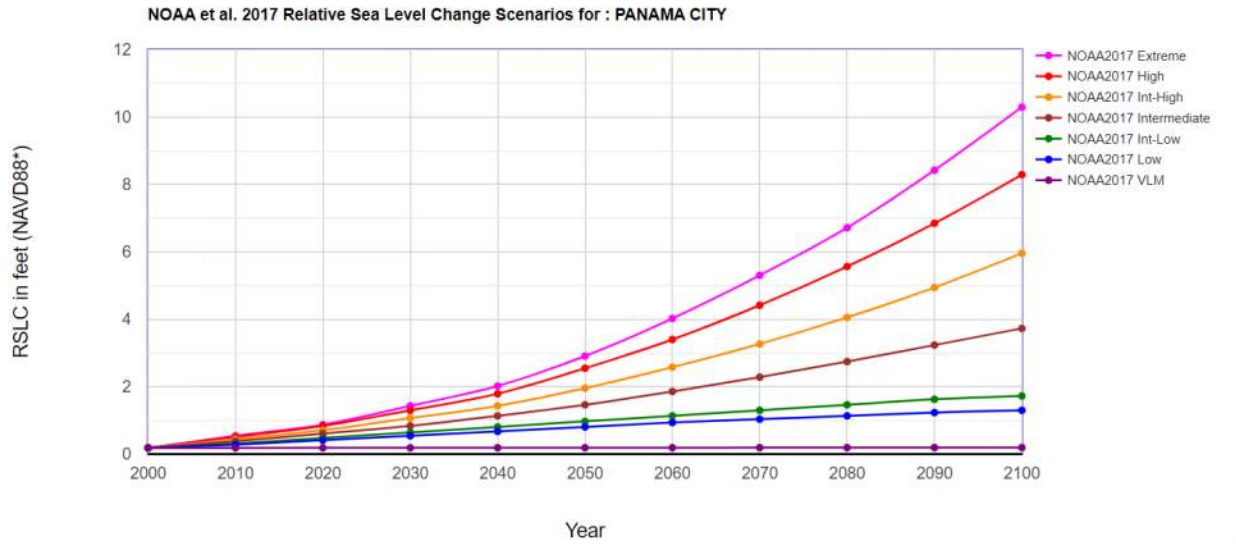

Figure 32. Relative Sea Level Change Scenarios for gauge 8729108, Panama City, FL. (Source: NOAA, 2017 available at https://cwbi-app.sec.usace.army.mil/rccslc/slcc_calc.html)

NOAA (2017) outlines five scenarios for sea level rise. The NFIP proposes the use of the intermediate high projection, which is 1.2 meters or 4 ft globally from current sea level elevations (**Error! Reference source not found.**).

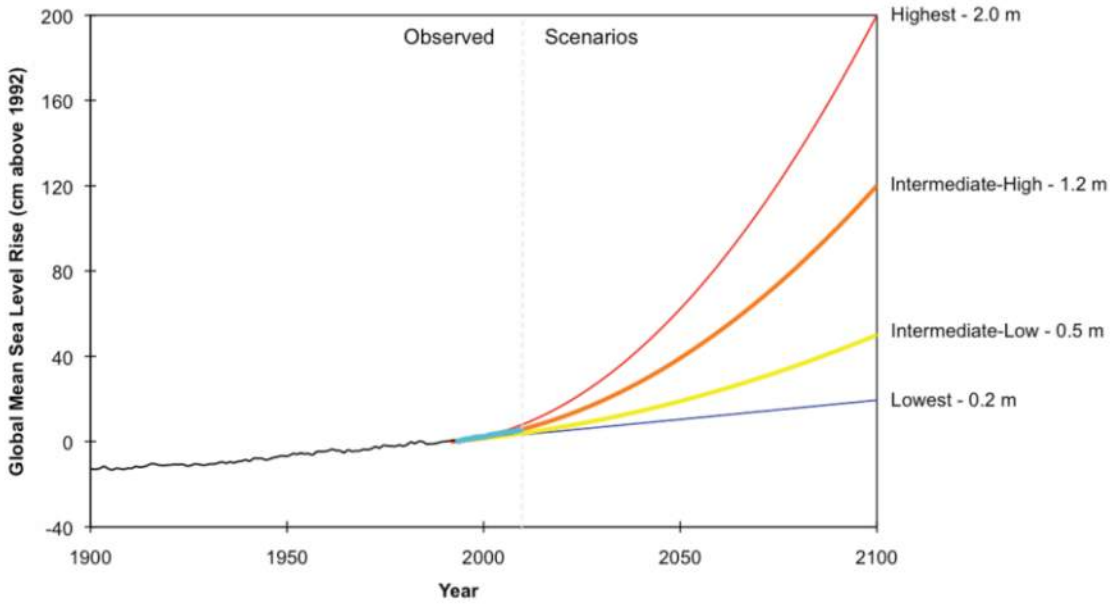

Figure 33. Graphic of global sea level rise projections from NOAA (2017).
(Source: NOAA, 2017 available at https://tidesandcurrents.noaa.gov/publications/techrpt83_Global_and_Regional_SLR_Scenarios_for_the_US_final.pdf)

As sea level rises, access to roads, bridges, rail, and transit could be at risk of flooding, causing the effects of sea level rise to spread indirectly throughout the entire transportation network, affecting the overall system performance. For example, the flooding of a critical road or facility access can cause a shifting of traffic flow causing congested conditions in other roadways that are not actually flooded. Since the roadway network would be unable to carry the traffic demand, the system would experience operational failure; as a result, causing travel times and delays. Moreover, the inundation of a critical access could cause transportation connectivity problems to essential infrastructure like ports or airports. Transportation infrastructure relies on the effectiveness of flood control and stormwater drainage systems for the transportation corridors. Road integrity relies on adequate drainage. The increased risk of severe flooding in Florida's low-lying terrain can adversely affect transportation infrastructure along the coastline; roads can be inundated, and roadway beds can be damaged. Sea level rise will cause increased water table levels (FDOT, 2012), as regional water tables cannot exist naturally below mean high tide (2 feet in Florida). Adding 3 feet of sea level rise on top of groundwater would compound the risk of flooding in low-lying areas. Road bases below 5 feet NVGD would become saturated under this scenario, likely causing premature base failure. As soil storage capacity is diminished due to rising

groundwater elevations associated with sea level rise, the potential for more frequently flooded roadways would likely damage pavements (FDOT, 2012). Hence sea level rise must be accounted for in WMPs in coastal areas. To allow flexibility in the analysis due to the range of increases within the different time periods, an approach that uses incremental increases of 1, 2, and 3 feet of sea level rise is suggested for modeling. The increments can work as threshold values in planning considerations in terms of allowing planners the ability to know ahead of time where the next set of vulnerable areas will be, to allow for a proactive response approach that can be matched to the observed future rates. Sea level rise is a major concern since nearly half the US population lives within 50 miles of the coast, involving most major commercial, residential, and economic enterprises. The effects of 5 ft sea level rise, King tide, and 1-day 100-year storm event are shown in Figure 34.

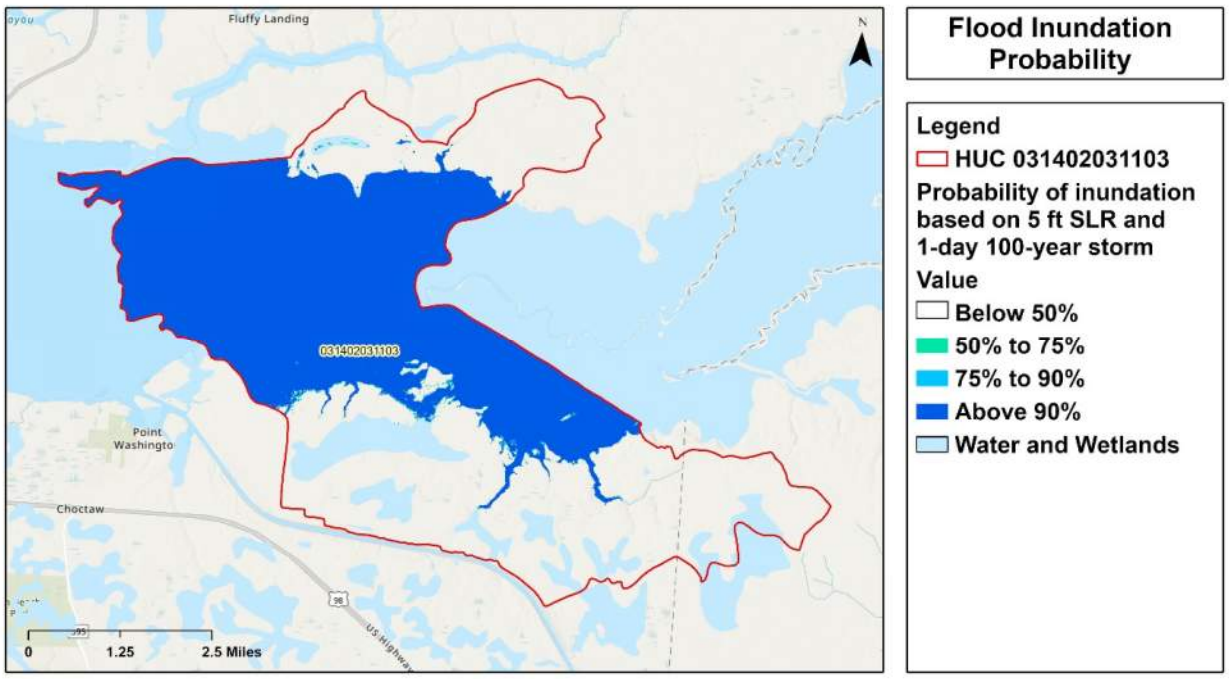

Figure 34. Flood Inundation Probability for a Sea level rise of 5 ft + 1-day 100-year storm event for HUC 031402031103 sub-watershed.
Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations.
Dark blue is area under 5 ft NAVD88 and potentially inundated at the 99th percentile tidal conditions. Processed by FAU.

2.4 Modeling Results

Error! Reference source not found. to **Error! Reference source not found.** are a series of maps that depict risk of flooding in the basin based on the following scenarios:

1. **3-day 25-year storm event**. Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 35)
2. **1-day 100-year storm event**. Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 36)
3. **1-day 10-year storm event.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 37)
4. **1-day 5-year storm event.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 38)
5. **Sea level rise of 1 ft + 3-day 25-year storm** (only coastal area and GW affected – GW layer rises 1 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 39)
6. **Sea level rise of 1 ft + 1-day 100-year storm** (only coastal area and GW affected – GW layer rises 1 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations storm (Figure 40)
7. **Sea level rise of 1 ft + 1-day 10-year storm** (only coastal area and GW affected – GW layer rises 1 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 41)
8. **Sea level rise of 1 ft + 1-day 5-year storm** (only coastal area and GW affected – GW layer rises 1 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 42)
9. **Sea level rise of 2 ft + 3-day 25-year storm** (only coastal area and GW affected – GW layer rises 2 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 43)
10. **Sea level rise of 2 ft + 1-day 100-year storm** (only coastal area and GW affected – GW layer rises 2 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 44)
11. **Sea level rise of 2 ft + 1-day 10-year storm** (only coastal area and GW affected – GW layer rises 2 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 45)
12. **Sea level rise of 2 ft + 1-day 5-year storm** (only coastal area and GW affected – GW layer rises 2 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 46)
13. **Sea level rise of 3 ft + 3-day 25-year storm** (only coastal area and GW affected – GW layer rises 3 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 47)
14. **Sea level rise of 3 ft + 1-day 100-year storm** (only coastal area and GW affected – GW layer rises 3 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 48)

15. **Sea level rise of 3 ft + 1-day 10-year storm** (only coastal area and GW affected – GW layer rises 3 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 49)
16. **Sea level rise of 3 ft + 1-day 5-year storm** (only coastal area and GW affected – GW layer rises 3 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 50)
17. **Sea level rise of 4 ft + 3-day 25-year storm** (only coastal area and GW affected – GW layer rises 4 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 51)
18. **Sea level rise of 4 ft + 1-day 100-year storm** (only coastal area and GW affected – GW layer rises 4 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 52)
19. **Sea level rise of 4 ft + 1-day 10-year storm** (only coastal area and GW affected – GW layer rises 4 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 53)
20. **Sea level rise of 4 ft + 1-day 5-year storm** (only coastal area and GW affected – GW layer rises 4 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 54)
21. **Sea level rise of 5 ft + 3-day 25-year storm** (only coastal area and GW affected – GW layer rises 5 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 55)
22. **Sea level rise of 5 ft + 1-day 100-year storm** (only coastal area and GW affected – GW layer rises 5 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 56)
23. **Sea level rise of 5 ft + 1-day 10-year storm** (only coastal area and GW affected – GW layer rises 5 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 57)
24. **Sea level rise of 5 ft + 1-day 5-year storm** (only coastal area and GW affected – GW layer rises 5 ft)**.** Note a 2.97 ft King Tide was also included based highest tide from NOAA tidal gauge stations (Figure 58)

In all scenarios, a considerable amount of flooding is noted at the river entrance to the HUC, extending to the wetland areas. As this basin connects to the ocean though Choctawhatchee River and Bay, SLR scenarios plays an important hole, implying a considered growth as the projected scenario of rising tides rises.

The design storm simulation determined that approximately 45% of the HUC total area or 14.21 mi^2 has a probability of inundation above 50% for a 3-day 25-year design storm. For comparison, approximately 45.1% of the HUC's total area, or 14.23 mi^2 would be expected to be

inundated during a 1-day 100-year design storm. Approximately 44.8% of the HUC's total area, or 14.14 mi², would be expected to be inundated during a 1-day 10-year design storm. Finally, approximately 43.8% of the HUC's total area, or 13.83 mi², would be expected to be inundated during the 1-day 5-year storm. **Error! Reference source not found.** compares the four storm events.

Table 7. HUC 031402031103 expected inundated area by storm event.

Storm Event	Area with probability of inundation below 50% (Sq Mi)	Area with probability of inundation above 50% (Sq Mi)	Area with probability of inundation below 50% (%)	Area with probability of inundation above 50% (%)
3-day 25-year	17.33	14.21	55.0%	45.0%
1-day 100-year	17.32	14.23	54.9%	45.1%
1-day 10-year	17.40	14.14	55.2%	44.8%
1-day 5-year	17.71	13.83	56.2%	43.8%

2.5 Risk and Vulnerability

The screening tool modeling exercise from the prior section identified areas within the communities that are vulnerable to flooding. Higher priority concerns should be those properties or assets that are considered essential and need to be kept in service during a flooding event. All other improvements are local. To help with prioritization, the following is suggested:

- Tier 1 - Critical facility protection (water/sewer utilities, public safety, hospitals, schools, power, shelters)
- Tier 2 - Essential facilities (groceries, pharmacies, roadways)
- Tier 3 - Economic centers (protecting jobs)
- Tier 4 - At risk communities
- Tier 5 - Other urban/suburban property
- Tier 6 - Agriculture/public property/vacant/undeveloped

Error! Reference source not found. outlines the priority of land use based on DOR land use codes from the property appraiser's office and assigns an associated priority level to each parcel. Note that for residential property, identifying at-risk communities (income, age, disability, health)

requires a further drilldown to the neighborhood level (i.e. wealthy neighborhoods with few older, poor health individuals would have a lower priority than at risk communities, which generally have lower value housing and denser development). In the latter case, more people are impacted, and those people have less ability to mitigate risk. Based on these priorities, the relative risk priority DOR land use codes were evaluated based on a scale of 1 to 6, where 1 is higher priority (more vulnerable) and 6 is the least priority (least vulnerable).

Table 8. Priority of Land Use based on (DOR) land use codes. Processed by FAU.

DOR (Use code)	**Description**	**TIER (Priority of Land Use)**
0	Vacant Residential	6

100	Parcel With no Values	6
101	Parcels With no Values (ROW - avenues, highways, arterials)	2
102	Parcels With no Values (Water)	6
103	Parcels With no Values (Rail)	2

Having assigned the risk priority from 1 to 6 in the DOR codes and the percentage of the parcel that floods during the applicable design storm, properties that are more critical to the function of the community can be identified. The methodology is to first convert the DOR code priority tier to its inverse scale by the following equation:

Consequence of risk factor = 7 – DOR Code Priority Tier

The flood risk factor from the screening tool is interpreted based on flooding probability. We take all parcels in tiers #1-4 that have a greater than 50% chance of flooding during a particular design storm and calculate the percent of the parcel that would flood during that event. The percentage is converted to a 6-point scale termed as the Flood Risk Factor, shown in **Error! Reference source not found.**.

Table 9. Flood Risk Factor Classification.

Percent of Parcel Flooded	Flood Risk Factor
90-100%	6
80-89%	5
70-79%	4
60-69%	3
50-59%	2
<50%	1

The priority is further developed by assigning 75% of the importance to the consequence of flooding and 25% importance to flood risk, or three times the importance to the consequence of flooding to come up with a composite score as follows:

Flood Risk Factor × 25% + Consequence of Risk Factor × 75% = Composite Score

Example: 1 × 25% + 6 × 75% = 4.75

Those higher priority properties that received the higher composite score are where the mitigation strategies and financial resources should focus first.

2.5.1 Results

Error! Reference source not found. to **Error! Reference source not found.** depict the HUC 031402031103 sub-watershed priority of land uses showing the critical facilities that should receive priority. The first map (**Error! Reference source not found.**) exclusively displays critical facility parcels within the HUC without any flooding. The second map (Figure 60) overlays critical facilities onto the 1-day 100-year storm event scenario, while the third map (**Error! Reference source not found.**) represents the same overlay within the context of 5 feet of sea level rise (SLR) combined with the 1-day 100-year storm event. **Error! Reference source not found.** is a mosaic showing critical facilities overlaid in the 5 feet SLR + 1-day 100-year storm event for the whole county.

Additionally, **Error! Reference source not found.** and **Error! Reference source not found.** illustrate the composite score for the HUC, which is the result of the calculations explained above, pinpointing parcels that should be prioritized. It considers only parcels classified as 1 to 4 tiers, and within the 50% probability of inundation area. **Error! Reference source not found.** represents the calculation for composite score based on 1-day 100-year storm event, while **Error! Reference source not found.** shows the calculation for composite score for the same storm event, but including a 5 feet of Sea Level Rise scenario. **Error! Reference source not found.** shows the same area zoomed out.

Please note that the composite score results display outcomes exclusively for parcels within the flooding path area. Consequently, for parcels outside this flooding path, the composite results will be null. The composite score combines the flooding path area with the land use priority results to identify the most vulnerable areas deserving of priority.

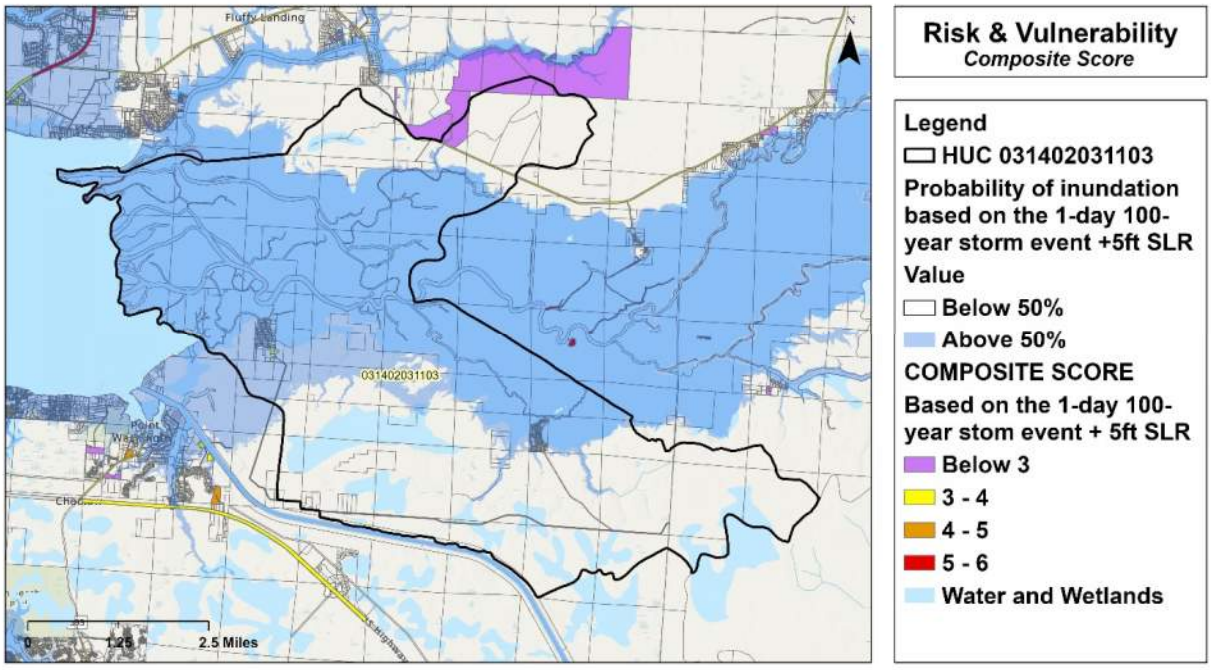

Figure 64. HUC 031402031103 sub-watershed Composite Score Risk map based on 1-day 100-year storm event + 5 ft. SRL, overlaid on the 1-day 100-year + 5 ft. SLR probability of inundation. Processed by FAU.

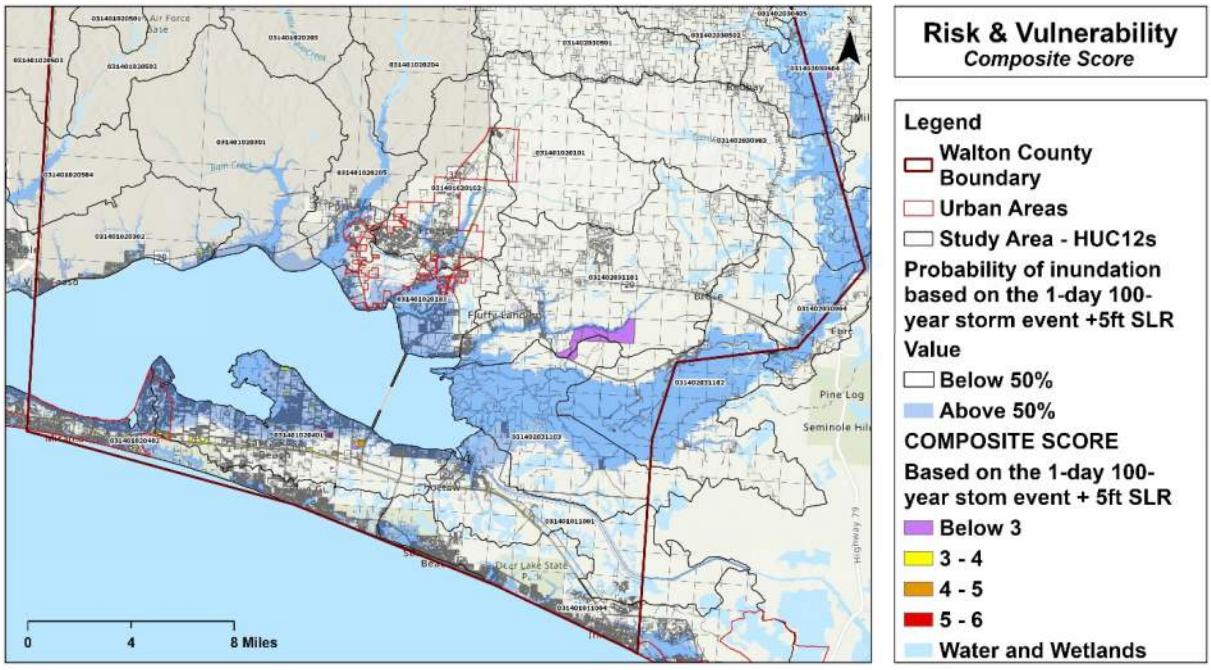

Figure 65. Coastal Area of Walton County (mosaic) - Composite Score Risk map overlaid on the 1-day 100-year + 5 ft. SLR storm event probability of inundation. Processed by FAU.

2.5.2 Solutions

Chapter 5 of the Watershed Master Plan for Walton County describes a list of possible gray and green stormwater strategies to combat flooding that can be implemented as solutions for the county. The same solutions can also be applied at the HUC level, including HUC 031402031103. A summary of these flood mitigation strategies is listed in **Error! Reference source not found.**. For more detailed information, please see Chapter 5-5.3 (Solutions).

Table 10. List of possible gray and green stormwater strategies to combat flooding.

Strategy Class	Implementation Strategy	Applications	Benefits	Cost	Barriers to Implementation
Green	Rainwater harvesting	Local, small scale, easily implemented in developed areas	Protects property, treats runoff	Under $5,000	Limited volume disposed of, so many are needed, maintenance
Gray	Pervious paving	Parking lots, patios, driveways, anything except paved roads due to traffic loading	Reduces roadway and parking lot flooding	$10-20/sf, requires bumpers and sub-base to maintain paver integrity	Must be maintained via vacuuming or the perviousness fades after 2-3 years

Strategy Class	Implementation Strategy	Applications	Benefits	Cost	Barriers to Implementation
Green	Detention	Common for new development, but difficult to retrofit; limited to open areas	Removes water from streets, reduces flooding	$200K/ac	Land availability, maintenance of pond, discharge location Uses up land that could otherwise be developed
Gray	Exfiltration Trench	Any low-lying area where stormwater collects and the water table is more than 3 ft below the surface; densely developed areas where retention is not available, roadways	Excess water drains to aquifer, some treatment provided	$250/ft	Significant damage to roadways for installation, maintenance needed, clogging issues reduce benefits
Gray	Central sewer installation	All areas where there are septic tanks. Mostly a water quality issue	Public health benefit of reducing discharges to lawns, canals, and groundwater from septic tanks	$15,000 per household	Cost, assessments against property owners, property rights issues
Green	Flood prone property acquisition	Regional agency - could be any low-lying areas	Removes flood prone areas from risk	$2K-$100K/ac depending on whether it is already developed	Difficult to implement if occupied, issues with willing sellers, cost, lack of funds for acquisition
Gray	Pump stations	Any low-lying area where stormwater collects, and there is a place to pump the excess stormwater to such as a canal; common for developed areas	Removes water from streets, reduces flooding	Start at $1.5 to 5 million each, number unclear without more study	NPDES permits, maintenance cost, land acquisition, discharge quality
Gray	Armored sewer systems	Any area where gravity sanitary sewers are installed	Keeps stormwater out of sanitary sewer system and reduces potential for disease spread from sewage overflows	$500/manhole	Limited expense beyond capital cost
Gray	Sea walls	Barrier islands and downtown coastal areas	Protects property	$1200/ft	Private property rights, neighbors

Strategy Class	Implementation Strategy	Applications	Benefits	Cost	Barriers to Implementation
Policy	Changes in land use	Applicable universally	Achieves flood risk mitigation by adjusting permitted land use	Low but may incur private property rights conflicts and litigation	Private property rights conflicts and litigation
Gray	Roadway base protection	Low-lying areas, coastal communities	Protects roads and access routes	$1 million per lane-mile	Cost, adjacent properties become uninsurable
Policy	Enhanced elevation of buildings	Developers would implement this for new construction	Reduced flood risk	Varies	Potential issues with building structure or latticework, and existing homes that are not elevated

2.5.3 Impacted Adjustment Areas

In the evaluation of flood risk management strategies within the framework of the National Flood Insurance Program Community Rating System (CRS), the concept of impact adjustment plays a pivotal role in determining the extent to which CRS-credited activities or elements influence the vulnerability of a community's Special Flood Hazard Area (SFHA) and the structures located within it. It is important to note that while the usual results of impact adjustment are related to the SFHA area, in this specific analysis, it was used 1-day 100-year storm event inundation area performed by FAU instead.

In this context, the following table presents a breakdown of the impact adjustment calculations for a 1-day 100-year storm event inundation. The values are expressed in acres and depict the areas of interest as well as the deductions considered in the evaluation process.

The outcomes of these calculations provide valuable insights into the impact adjustment scenarios:

With ALL State Lands:

This scenario reflects the remaining inundation area after accounting for deductions A, B, and C. It represents the effect of CRS-credited activities without considering the influence of state lands in managing flood risks.

With NO State Lands:

In this case, the remaining inundation area is determined by considering all deductions, including state lands (both open space and not open space– see **Error! Reference source not found.**).

These calculations highlight the dynamic nature of impact adjustment within the CRS framework. By accurately gauging the influence of individual elements, the system ensures that credit allocations align closely with a community's efforts in flood risk mitigation.

Table 11. Impacted Adjustment Areas for HUC 031402031103. Processed by FAU.

AREAS	**ACRES**
HUC-12 Sub-watershed: 031402031103	20187.04
All of the 1-day 100-year storm event inundation	**9104.14**
Subtract	
A. Bodies of Water in 1-day 100-year inundation > 10 acres	7713.99
B. Federal Land in 1-day 100-year inundation > 10 acres	0.00
C. Reservation/Tribal Land in 1-day 100-year inundation > 10 acres	0
D. State Land in 1-day 100-year inundation > 10 acres that is open space	548.71
E. State Land in 1-day 100-year inundation > 10 acres that is NOT open space	11.25
The remainder is either:	
With ALL State Lands: All of the 1-day 100-year inundation minus (A+B+C) or	1390.15
With NO State Lands: All of the 1-day 100-year inundation minus (A+B+C+D+E)	830.19

2.5.4 Repetitive Loss Property Map

A Repetitive Loss (RL) property is a building that has had two or more loss or damage due to a specific hazard, such as floods, hurricanes, or other natural disasters, over $1,000 each, paid by the National Flood Insurance Program (NFIP) within any ten-year period since 1978. There are more than 122,000 RL properties in the nationwide (FEMA, 2005).

These data are essential for assessing the vulnerability of certain areas to recurrent losses and for developing strategies to mitigate the risks. However, due to privacy concerns, the data cannot be openly shared with the public. For this reason, the data were converted into a hot spot analysis map. These maps, instead of identifying the specific location of the repetitive loss properties, highlight clusters of repetitive loss claims and areas where the probability of repetitive losses is higher than would be expected by random chance. In other words, it helps pinpoint locations that have a higher concentration of properties prone to repetitive losses. **Error! Reference source not found.** indicates the results from hot spot analysis in point data, showing aggregated counts, and raster data, showing the estimated probability of repetitive loss.

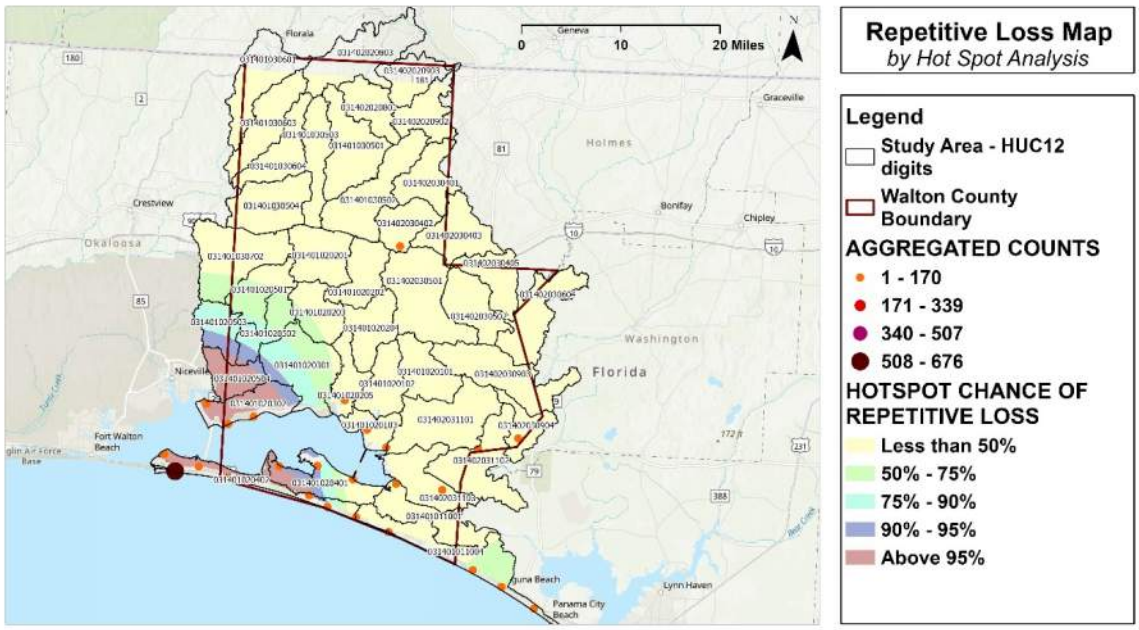

Figure 66. Repetitive Loss map for Walton County by Hot Spot Analysis. Processed by FAU. (Source Data: FEMA)

2.5.5 Priority Projects

While the basin does not have a significant amount of developed land, some parcels fall within the flood zone due to the area's susceptibility to significant flooding in both 1-day 100-year storm events and 1-day 100-year + 5 feet sea level rise scenarios. In terms of land use priority, there are numerous parcels in tiers 2 (roads), 4, and 5 within the flooding zone. Tier 1 priority parcels, however, are not affected by flooding.

Examining the composite score, there are a total of 59 parcels within the flood zone that require attention. Among them, three are in the score range of 5-6, all of which are roads (Nancy's Cut Off, Magnolia Run, and Rushing Cutoff), representing the highest priority for intervention. Additionally, there are three parcels, also roads (Steele Field Rd, Co Highway 3280, and Bunker Road), with scores in the range of 4-5, and 44 parcels with scores in the range of 3-4, all of which are mobile homes. Finally, there are 11 parcels with scores below 3, comprising 5 orphanages and 6 mobile homes.

AR.0EXECUTIVE SUMMARY

The goal of this appendix to the watershed plan is to illustrate the 25-year, 1-day modeling results using the same methodologies outlined in Section 3.2 of the watershed plan for the 1-day, 5-, 10-, and 100-yr storm events. The following figures are for informational purposes, and the events and results outlined in the watershed plan exceed the guidance criteria to include storm events that are "at least" the 25-year storm event.

1.0 25-Year, 1-Day Storm Event Results

Figure 1 through Figure 11 illustrate the 25-year, 1-day storm event results for the Walton County modeling analysis.

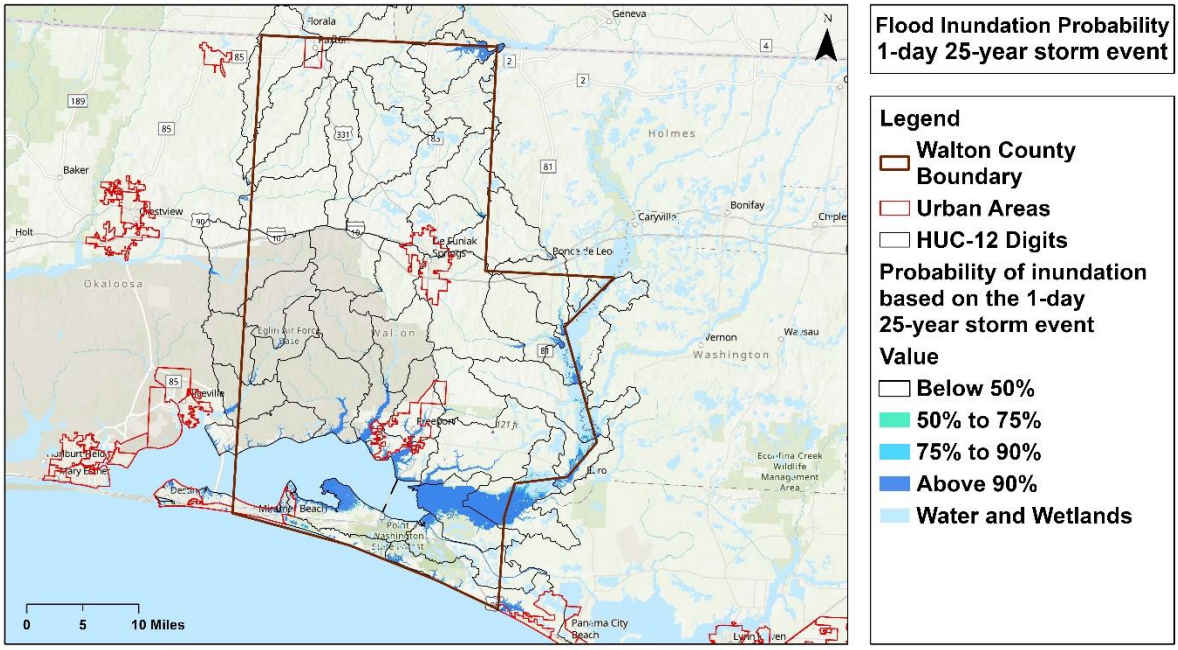

Figure 1. Probability of flood risk map for Walton County for the 1-day, 25-year storm event

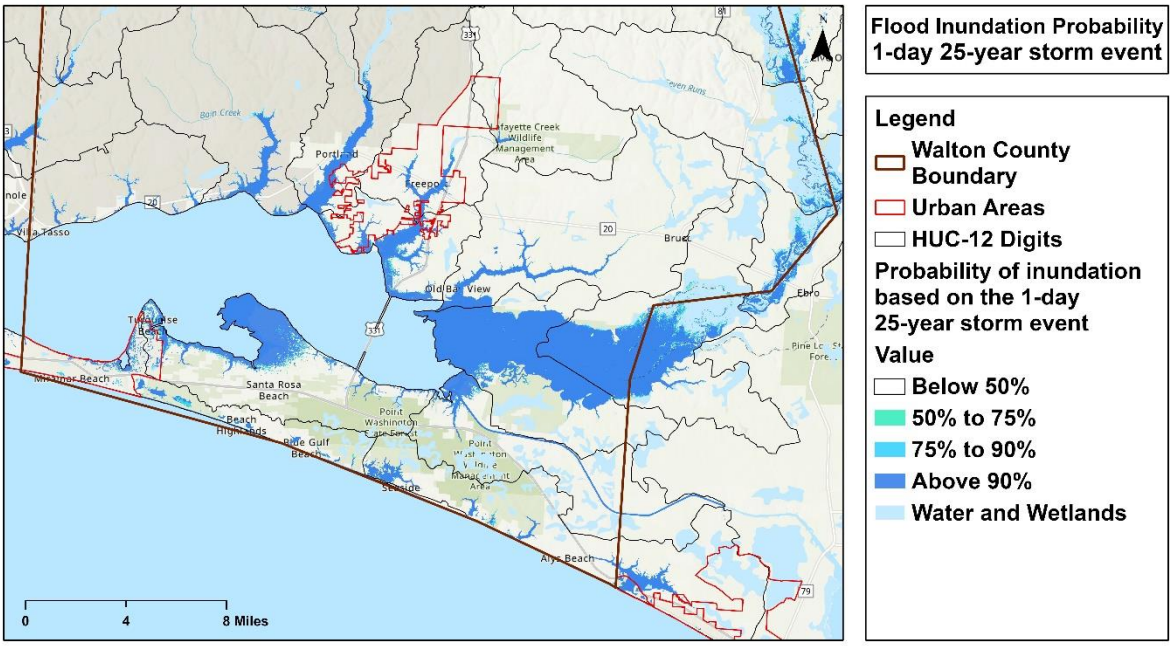

Figure 2. Probability of flood risk map for Coastal Walton County for the 1-day, 25 flood event

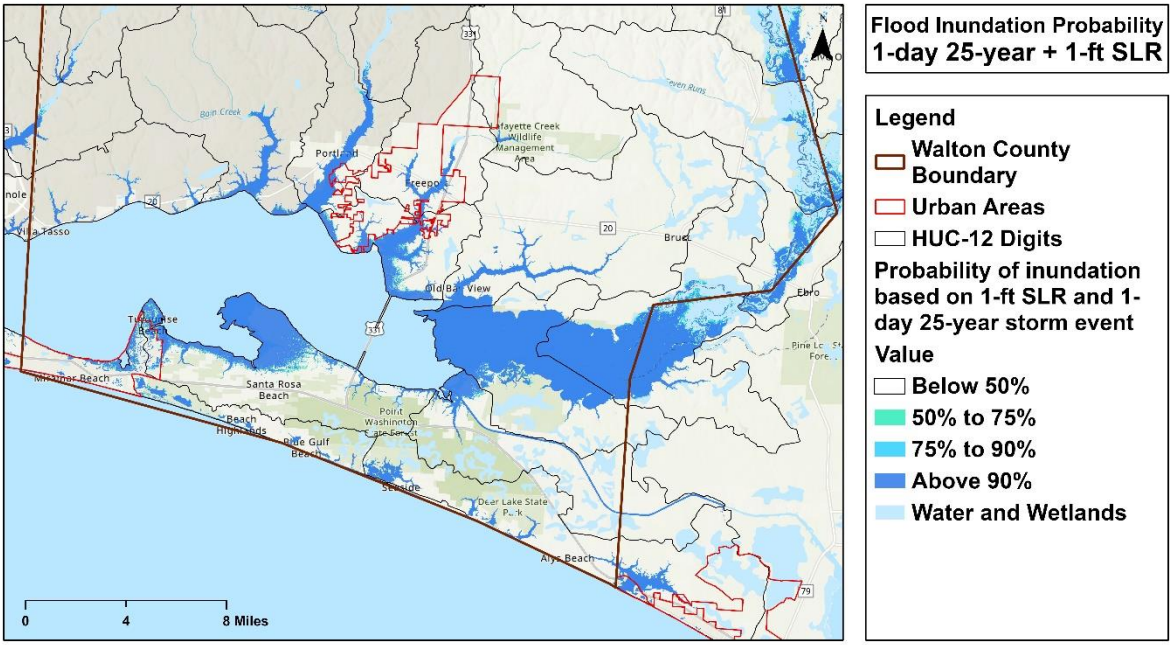

Figure 3. Probability of flood risk map for Walton County for the 1-day, 25-year flood event with 1 ft SLR
